abs : $ -> $
++ abs(x) represents the Fortran intrinsic function ABS

sqrt : $ -> $
++ sqrt(x) represents the Fortran intrinsic function SQRT

exp : $ -> $
++ exp(x) represents the Fortran intrinsic function EXP

log : $ -> $
++ log(x) represents the Fortran intrinsic function LOG

log10 : $ -> $
++ log10(x) represents the Fortran intrinsic function LOG10

sin : $ -> $
++ sin(x) represents the Fortran intrinsic function SIN

cos : $ -> $
++ cos(x) represents the Fortran intrinsic function COS

tan : $ -> $
++ tan(x) represents the Fortran intrinsic function TAN

asin : $ -> $
++ asin(x) represents the Fortran intrinsic function ASIN

acos : $ -> $
++ acos(x) represents the Fortran intrinsic function ACOS

atan : $ -> $
++ atan(x) represents the Fortran intrinsic function ATAN

sinh : $ -> $
++ sinh(x) represents the Fortran intrinsic function SINH

cosh : $ -> $
++ cosh(x) represents the Fortran intrinsic function COSH

tanh : $ -> $

```

```

++ tanh(x) represents the Fortran intrinsic function TANH

pi : () -> $
++ pi(x) represents the NAG Library function X01AAF which returns
++ an approximation to the value of pi

variables : $ -> L S
++ variables(e) return a list of all the variables in \spad{e}.

useNagFunctions : () -> Boolean
++ useNagFunctions() indicates whether NAG functions are being used
++ for mathematical and machine constants.

useNagFunctions : Boolean -> Boolean
++ useNagFunctions(v) sets the flag which controls whether NAG functions
++ are being used for mathematical and machine constants. The previous
++ value is returned.

=====

Fraction examples

=====

The Fraction domain implements quotients. The elements must belong to a domain of category IntegralDomain: multiplication must be commutative and the product of two non-zero elements must not be zero. This allows you to make fractions of most things you would think of, but don't expect to create a fraction of two matrices! The abbreviation for Fraction is FRAC.

Use / to create a fraction.

```

a := 11/12
11
--
12

```

Type: Fraction Integer

```

b := 23/24
  23
  --
  24

```

Type: Fraction Integer

The standard arithmetic operations are available.

```

3 - a*b**2 + a + b/a
313271
-----
76032

```

Type: Fraction Integer

Extract the numerator and denominator by using numer and denom, respectively.

```

numer(a)
  11

```

Type: PositiveInteger

```

denom(b)
  24

```

Type: PositiveInteger

Operations like max, min, negative?, positive? and zero? are all available if they are provided for the numerators and denominators.

Don't expect a useful answer from factor, gcd or lcm if you apply them to fractions.

```

r := (x**2 + 2*x + 1)/(x**2 - 2*x + 1)
  2
  x  + 2x + 1
  -----
  2
  x  - 2x + 1

```

Type: Fraction Polynomial Integer

Since all non-zero fractions are invertible, these operations have trivial definitions.

```

factor(r)
  2
  x  + 2x + 1
  -----
  2
  x  - 2x + 1

```

Type: Factored Fraction Polynomial Integer

Use map to apply factor to the numerator and denominator, which is probably what you mean.

```
map(factor,r)
      2
(x + 1)
-----
      2
(x - 1)
```

Type: Fraction Factored Polynomial Integer

Other forms of fractions are available. Use continuedFraction to create a continued fraction.

```
continuedFraction(7/12)
      1 |      1 |      1 |      1 |
+---+ + +---+ + +---+ + +---+
| 1      | 1      | 2      | 2
Type: ContinuedFraction Integer
```

Use partialFraction to create a partial fraction.

```
partialFraction(7,12)
      3  1
1 - -- + -
      2  3
      2
Type: PartialFraction Integer
```

Use conversion to create alternative views of fractions with objects moved in and out of the numerator and denominator.

```
g := 2/3 + 4/5%i
      2  4
- + - %i
      3  5
Type: Complex Fraction Integer

g :: FRAC COMPLEX INT
      10 + 12%i
-----
      15
Type: Fraction Complex Integer
```

— domain FRAC Fraction —

```

)abbrev domain FRAC Fraction
++ Author: Mark Botch
++ Date Last Updated: 12 February 1992
++ Basic Functions: Field, numer, denom
++ References:
++ Cor100 According to Abramowitz and Stegun or arccoth needn't be Uncouth
++ Fate01a A Critique of OpenMath and Thoughts on Encoding Mathematics
++ Description:
++ Fraction takes an IntegralDomain S and produces
++ the domain of Fractions with numerators and denominators from S.
++ If S is also a GcdDomain, then gcd's between numerator and
++ denominator will be cancelled during all operations.

```

```

++ Fractional ideals in a framed algebra.

FractionalIdeal(R, F, UP, A) : SIG == CODE where
  R : EuclideanDomain
  F : QuotientFieldCategory R
  UP : UnivariatePolynomialCategory F
  A : Join(FramedAlgebra(F, UP), RetractableTo F)

VF ==> Vector F
VA ==> Vector A
UPA ==> SparseUnivariatePolynomial A
QF ==> Fraction UP

SIG ==> Group with

  ideal : VA -> %
    ++ ideal([f1,...,fn]) returns the ideal \spad{[f1,...,fn]}.

  basis : % -> VA
    ++ basis((f1,...,fn)) returns the vector \spad{[f1,...,fn]}.

  norm : % -> F
    ++ norm(I) returns the norm of the ideal I.

  numer : % -> VA
    ++ numer(1/d * (f1,...,fn)) = the vector \spad{[f1,...,fn]}.

  denom : % -> R
    ++ denom(1/d * (f1,...,fn)) returns d.

  minimize : % -> %
    ++ minimize(I) returns a reduced set of generators for \spad{I}.

  randomLC: (NonNegativeInteger, VA) -> A
    ++ randomLC(n,x) should be local but conditional.

— domain FMONOID FreeMonoid —

```

)abbrev domain FMONOID FreeMonoid
++ Author: Stephen M. Watt
++ Date Last Updated: 6 June 1991
++ Description:
++ Free monoid on any set of generators
++ The free monoid on a set S is the monoid of finite products of
++ the form \spad{reduce(*,[si ** ni])} where the si's are in S, and the ni's
++ are nonnegative integers. The multiplication is not commutative.

FreeMonoid(S) : SIG == CODE where
  S : SetCategory

  NNI ==> NonNegativeInteger
  REC ==> Record(gen: S, exp: NonNegativeInteger)
  Ex ==> OutputForm

  SIG ==> Join(Monoid, RetractableTo S) with

    "*" : (S, $) -> $
      ++ s * x returns the product of x by s on the left.

    "*" : ($, S) -> $
      ++ x * s returns the product of x by s on the right.

    "***" : (S, NonNegativeInteger) -> $
      ++ s ** n returns the product of s by itself n times.

    hclf : ($, $) -> $
      ++ hclf(x, y) returns the highest common left factor of x and y,
      ++ the largest d such that \spad{x = d a} and \spad{y = d b}.

    hcrf : ($, $) -> $
      ++ hcrf(x, y) returns the highest common right factor of x and y,
      ++ the largest d such that \spad{x = a d} and \spad{y = b d}.

    lquo : ($, $) -> Union($, "failed")
      ++ lquo(x, y) returns the exact left quotient of x by y
      ++ q such that \spad{x = y * q},

```

```

    ++ "failed" if x is not of the form \spad{y * q}.

rquo : ($, $) -> Union($, "failed")
  ++ rquo(x, y) returns the exact right quotient of x by y
  ++ q such that \spad{x = q * y},
  ++ "failed" if x is not of the form \spad{q * y}.

divide : ($, $) -> Union(Record(lm: $, rm: $), "failed")
  ++ divide(x, y) returns the left and right exact quotients of
  ++ x by y, \spad{[l, r]} such that \spad{x = l * y * r},
  ++ "failed" if x is not of the form \spad{l * y * r}.

overlap : ($, $) -> Record(lm: $, mm: $, rm: $)
  ++ overlap(x, y) returns \spad{[l, m, r]} such that
  ++ \spad{x = l * m}, \spad{y = m * r} and l and r have no overlap,
  ++ \spad{overlap(l, r) = [l, 1, r]}.

size : $ -> NNI
  ++ size(x) returns the number of monomials in x.

factors : $ -> List Record(gen: S, exp: NonNegativeInteger)
  ++ factors(a1\^e1,...,an\^en) returns \spad{[[a1, e1],...,[an, en]]}.

nthExpon : ($, Integer) -> NonNegativeInteger
  ++ nthExpon(x, n) returns the exponent of the nth monomial of x.

nthFactor : ($, Integer) -> S
  ++ nthFactor(x, n) returns the factor of the nth monomial of x.

mapExpon : (NNI -> NNI, $) -> $
  ++ mapExpon(f, a1\^e1 ... an\^en)
  ++ returns \spad{a1\^f(e1) ... an\^f(en)}.

mapGen : (S -> S, $) -> $
  ++ mapGen(f, a1\^e1 ... an\^en) returns
  ++ \spad{f(a1)\^e1 ... f(an)\^en}.

if S has OrderedSet then OrderedSet

=====
FullPartialFractionExpansion expansion
=====
```

The domain FullPartialFractionExpansion implements factor-free conversion of quotients to full partial fractions.

Our examples will all involve quotients of univariate polynomials with rational number coefficients.

```
Fx := FRAC UP(x, FRAC INT)
      Fraction UnivariatePolynomial(x, Fraction Integer)
      Type: Domain
```

Here is a simple-looking rational function.

```
f : Fx := 36 / (x**5-2*x**4-2*x**3+4*x**2+x-2)
          36
-----
      5      4      3      2
      x  - 2x  - 2x  + 4x  + x - 2
      Type: Fraction UnivariatePolynomial(x, Fraction Integer)
```

We use fullPartialFraction to convert it to an object of type FullPartialFractionExpansion.

```
g := fullPartialFraction f
      4      4      --+      - 3%A - 6
      ---- - ---- +   >  -----
      x - 2   x + 1   --+      2
                        2      (x - %A)
                        %A  - 1= 0
      Type: FullPartialFractionExpansion(Fraction Integer,
      UnivariatePolynomial(x, Fraction Integer))
```

Use a coercion to change it back into a quotient.

```
g :: Fx
          36
-----
      5      4      3      2
      x  - 2x  - 2x  + 4x  + x - 2
```

```

x  - 2x  - 2x  + 4x  + x - 2
Type: Fraction UnivariatePolynomial(x,Fraction Integer)

```

Full partial fractions differentiate faster than rational functions.

```

g5 := D(g, 5)
      480      480      ---+      2160%A + 4320
- ---- + ---- + > ----
      6      6      ---+      7
      (x - 2)  (x + 1)  2      (x - %A)
      %A - 1 = 0
Type: FullPartialFractionExpansion(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))

```

```

f5 := D(f, 5)
      10      9      8      7      6
- 544320x  + 4354560x  - 14696640x  + 28615680x  - 40085280x
+
      5      4      3      2
46656000x  - 39411360x  + 18247680x  - 5870880x  + 3317760x + 246240
/
      20      19      18      17      16      15      14      13
x  - 12x  + 53x  - 76x  - 159x  + 676x  - 391x  - 1596x

+
      4      3      2
276x  - 1184x  + 208x  + 192x - 64
Type: Fraction UnivariatePolynomial(x,Fraction Integer)

```

We can check that the two forms represent the same function.

```

g5::Fx - f5
0
Type: Fraction UnivariatePolynomial(x,Fraction Integer)

```

Here are some examples that are more complicated.

```

f : Fx := (x**5 * (x-1)) / ((x**2 + x + 1)**2 * (x-2)**3)
      6      5
      x  - x
-----
      7      6      5      3      2
x  - 4x  + 3x  + 9x  - 6x  - 4x - 8
Type: Fraction UnivariatePolynomial(x,Fraction Integer)

```

```

g := fullPartialFraction f
      1952      464      32
----- ---- --
      179      135
- ---- %A + ----

```

$$\frac{2401}{x^2 - 2} + \frac{343}{(x - 2)^2} + \frac{49}{(x - 2)^3} + \frac{1}{(x - \%A)^2} > \frac{2401}{x - \%A}$$

$$\%A^2 + \%A + 1 = 0$$

$$+ \frac{37}{1029} \%A + \frac{20}{1029} > \frac{1}{(x - \%A)^2}$$

$$\%A^2 + \%A + 1 = 0$$

Type: FullPartialFractionExpansion(Fraction Integer,UnivariatePolynomial(x,Fraction Integer))

This verification takes much longer than the conversion to partial fractions.

```
g :: Fx - f
0
                                     Type: Fraction UnivariatePolynomial(x,Fraction Integer)
```

Use PartialFraction for standard partial fraction decompositions.

For more information, see the paper: Bronstein, M and Salvy, B.
"Full Partial Fraction Decomposition of Rational Functions,"
Proceedings of ISSAC'93, Kiev, ACM Press.

MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
=====

```

DistributedMultivariatePolynomial which is abbreviated as DMP and HomogeneousDistributedMultivariatePolynomial, which is abbreviated as HDMP, are very similar to MultivariatePolynomial except that they are represented and displayed in a non-recursive manner.

```

(d1,d2,d3) : DMP([z,y,x],FRAC INT)
              Type: Void

```

The constructor DMP orders its monomials lexicographically while HDMP orders them by total order refined by reverse lexicographic order.

```

d1 := -4*z + 4*y**2*x + 16*x**2 + 1
      2      2
      - 4z + 4y x + 16x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

```

d2 := 2*z*y**2 + 4*x + 1
      2
      2z y + 4x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

```

d3 := 2*z*x**2 - 2*y**2 - x
      2      2
      2z x - 2y - x
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

These constructors are mostly used in Groebner basis calculations.

```

groebner [d1,d2,d3]
      1568 6 1264 5 6 4 182 3 2047 2 103 2857
[z - ---- x - ---- x + --- x + --- x - ---- x - ---- x - ----,
 2745 305 305 549 610 2745 10980
 2 112 6 84 5 1264 4 13 3 84 2 1772 2
y + ---- x - --- x - ---- x - --- x + --- x + ---- x + ----,
 2745 305 305 549 305 2745 2745
 7 29 6 17 4 11 3 1 2 15 1
x + -- x - -- x - -- x + -- x + -- x + -]
 4 16 8 32 16 4
      Type: List DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

```

(n1,n2,n3) : HDMP([z,y,x],FRAC INT)
              Type: Void

```

```

n1 := d1
      2      2
    4y x + 16x - 4z + 1
Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

n2 := d2
      2
    2z y + 4x + 1
Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

n3 := d3
      2      2
    2z x - 2y - x
Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

Note that we get a different Groebner basis when we use the HDMP polynomials, as expected.

```

groebner [n1,n2,n3]
      4      3      3      2      1      1      4      29      3      1      2      7      9      1
[y + 2x - - x + - z - -, x + - x - - y - - z x - - x - -,
      2      2      8      4      8      4      16      4
      2      1      2      2      1      2      2      1
z y + 2x + -, y x + 4x - z + -, z x - y - - x,
      2      2      4      2
      2      2      2      1      3
z - 4y + 2x - - z - - x]
      4      2
Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
Fraction Integer)

```

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings. This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

Axiom can work with grlex order. For example, suppose we want grlex order on the rationals with $x > y$.

```
Grlex:=GDMP([x,y],FRAC INT,ODP(2,NNI,totalLex$ORDFUNS(2,NNI)))
```

The GDMP can be used to create an Axiom type of any monomial order, and totalLex is the function which orders exponent vectors using grlex. By declaring polynomials to be of type Grlex, you can now compute Groebner bases using grlex with $x > y$. Note that type conversion doesn't work between Grlex and the monomial orders created by DMP and HDMP, though it is possible to write type conversion routines. So

```
(1) -> Grlex:=GDMP([x,y],FRAC INT,ODP(2,NNI,totalLex$ORDFUNS(2,NNI)))
```

```
(1)
GeneralDistributedMultivariatePolynomial([x,y],Fraction(Integer),
OrderedDirectProduct(2,NonNegativeInteger,
theMap(ORDFUNS;totalLex;2VB;2,0)))
```

Type: Domain

```
(2) -> f:Grlex:=x^3 + 3*y^2
```

$$(2) \quad x^3 + 3y^2$$

```
(3) -> g:Grlex:=x^2 + y
```

$$(3) \quad x^2 + y$$

```
(4) -> h:Grlex:=x + 2*x*y
```

$$(4) \quad 2xy + x$$

```
(5) -> normalForm(f,[g,h])
```

$$(5) \quad 3y^2 + \frac{1}{2}x$$

```
(6) -> gb:=groebner([g,h])
```

$$(6) \quad [x^2 + y, xy + \frac{1}{2}x, y^2 + \frac{1}{2}y]$$

More generally, you can combine variable order and lexical order as in

```
f:=4*x*y^2*z + 4*z^2 - 5*x^3 + 7*x^2*z^2
```

$$(1) \quad (7x^2 + 4)z^2 + 4xyz^2 - 5x^3$$

```
Grlex1:=GDMP([x,y,z],FRAC INT,ODP(3,NNI,totalLex$ORDFUNS(3,NNI)))
```

```
(2)
GeneralDistributedMultivariatePolynomial([x,y,z],Fraction(Integer),
OrderedDirectProduct(3,NonNegativeInteger,
theMap(ORDFUNS;totalLex;2VB;2,443)))
```

Type: Domain

```
gr1:Grlex1:=4*x*y^2*z + 4*z^2 - 5*x^3 + 7*x^2*z^2
```

$$(3) \quad 7x^2z^2 + 4x^2yz - 5x^3 + 4z^2$$

```
Grlex2:=GDMP([y,z,x],FRAC INT,ODP(3,NNI,totalLex$ORDFUNS(3,NNI)))
```

```
(4)
GeneralDistributedMultivariatePolynomial([y,z,x],Fraction(Integer),
OrderedDirectProduct(3,NonNegativeInteger,
theMap(ORDFUNS;totalLex;2VB;2,443)))
```

Type: Domain

```
gr2:Grlex2:=4*x*y^2*z + 4*z^2 - 5*x^3 + 7*x^2*z^2
```

$$(5) \quad 4y^2zx + 7z^2x^2 - 5x^3 + 4z^2$$

```
Grlex3:=GDMP([x,y,z],FRAC INT,ODP(3,NNI,pureLex$ORDFUNS(3,NNI)))
```

```
(6)
GeneralDistributedMultivariatePolynomial([x,y,z],Fraction(Integer),
OrderedDirectProduct(3,NonNegativeInteger,
theMap(ORDFUNS;pureLex;2VB;1,443)))
```

Type: Domain

```
gr3:Grlex3:=4*x*y^2*z + 4*z^2 - 5*x^3 + 7*x^2*z^2
```

$$(7) \quad -5x^3 + 7x^2z^2 + 4x^2yz + 4z^2$$

```
Grlex4:=GDMP([y,z,x],FRAC INT,ODP(3,NNI,reverseLex$ORDFUNS(3,NNI)))
```

```
(8)
GeneralDistributedMultivariatePolynomial([y,z,x],Fraction(Integer),
OrderedDirectProduct(3,NonNegativeInteger,
theMap(ORDFUNS;reverseLex;2VB;3,443)))
```

Type: Domain

```
gr4:Grlex4:=4*x*y^2*z + 4*z^2 - 5*x^3 + 7*x^2*z^2
```

$$(9) \quad 4y^2zx + 7z^2x^2 - 5x^3 + 4z^2$$

— domain GDMP GeneralDistributedMultivariatePolynomial —

```

)abbrev domain GDMP GeneralDistributedMultivariatePolynomial
++ Author: Barry Trager
++ References:
++ Cox07 Ideals, varieties and algorithms
++ Description:
++ This type supports distributed multivariate polynomials
++ whose variables are from a user specified list of symbols.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.
++ The term ordering is specified by its third parameter.
++ Suggested types which define term orderings include:
++ \spadtype{DirectProduct}, \spadtype{HomogeneousDirectProduct},
++ \spadtype{SplitHomogeneousDirectProduct} and finally
++ \spadtype{OrderedDirectProduct} which accepts an arbitrary user
++ function to define a term ordering.

```

++   Springer-Verlag, Heidelberg, 1980
++ Description:
++ AlgebraGenericElementPackage allows you to create generic elements
++ of an algebra, the scalars are extended to include symbolic
++ coefficients

GenericNonAssociativeAlgebra(R,n,ls,gamma) : SIG == CODE where
  R : CommutativeRing
  n : PositiveInteger
  ls : List Symbol
  gamma : Vector Matrix R

NNI ==> NonNegativeInteger
V ==> Vector
PR ==> Polynomial R
FPR ==> Fraction Polynomial R
SUP ==> SparseUnivariatePolynomial
S ==> Symbol

SIG ==> Join(FramedNonAssociativeAlgebra(FPR), _
  LeftModule(SquareMatrix(n,FPR)) ) with

coerce : Vector FPR -> %
++ coerce(v) assumes that it is called with a vector
++ of length equal to the dimension of the algebra, then
++ a linear combination with the basis element is formed

leftUnits : () -> Union(Record(particular: %, basis: List %), "failed")
++ leftUnits() returns the affine space of all left units of the
++ algebra, or \spad{"failed"} if there is none

rightUnits : () -> Union(Record(particular: %, basis: List %), "failed")
++ rightUnits() returns the affine space of all right units of the
++ algebra, or \spad{"failed"} if there is none

generic : () -> %
++ generic() returns a generic element, the linear combination
++ of the fixed basis with the symbolic coefficients
++ \spad{%x1,%x2,...}

```

```

generic : Symbol -> %
++ generic(s) returns a generic element, the linear combination
++ of the fixed basis with the symbolic coefficients
++ \spad{s1,s2,...}

generic : Vector Symbol -> %
++ generic(vs) returns a generic element, the linear combination
++ of the fixed basis with the symbolic coefficients
++ \spad{vs};
++ error, if the vector of symbols is too short

generic : Vector % -> %
++ generic(ve) returns a generic element, the linear combination
++ of \spad{ve} basis with the symbolic coefficients
++ \spad{%x1,%x2,...}

generic : (Symbol, Vector %) -> %
++ generic(s,v) returns a generic element, the linear combination
++ of v with the symbolic coefficients
++ \spad{s1,s2,...}

generic : (Vector Symbol, Vector %) -> %
++ generic(vs,ve) returns a generic element, the linear combination
++ of \spad{ve} with the symbolic coefficients \spad{vs}
++ error, if the vector of symbols is shorter than the vector of
++ elements

if R has IntegralDomain then

leftRankPolynomial : () -> SparseUnivariatePolynomial FPR
++ leftRankPolynomial() returns the left minimal polynomial
++ of the generic element

genericLeftMinimalPolynomial : % -> SparseUnivariatePolynomial FPR
++ genericLeftMinimalPolynomial(a) substitutes the coefficients
++ of {em a} for the generic coefficients in
++ \spad{leftRankPolynomial()}

genericLeftTrace : % -> FPR
++ genericLeftTrace(a) substitutes the coefficients
++ of \spad{a} for the generic coefficients into the
++ coefficient of the second highest term in
++ \spadfun{leftRankPolynomial} and changes the sign.
++ This is a linear form

genericLeftNorm : % -> FPR
++ genericLeftNorm(a) substitutes the coefficients
++ of \spad{a} for the generic coefficients into the
++ coefficient of the constant term in \spadfun{leftRankPolynomial}
++ and changes the sign if the degree of this polynomial is odd.

```

```

++ This is a form of degree k

rightRankPolynomial : () -> SparseUnivariatePolynomial FPR
++ rightRankPolynomial() returns the right minimal polynomial
++ of the generic element

genericRightMinimalPolynomial : % -> SparseUnivariatePolynomial FPR
++ genericRightMinimalPolynomial(a) substitutes the coefficients
++ of \spad{a} for the generic coefficients in
++ \spadfun{rightRankPolynomial}

genericRightTrace : % -> FPR
++ genericRightTrace(a) substitutes the coefficients
++ of \spad{a} for the generic coefficients into the
++ coefficient of the second highest term in
++ \spadfun{rightRankPolynomial} and changes the sign

genericRightNorm : % -> FPR
++ genericRightNorm(a) substitutes the coefficients
++ of \spad{a} for the generic coefficients into the
++ coefficient of the constant term in \spadfun{rightRankPolynomial}
++ and changes the sign if the degree of this polynomial is odd

genericLeftTraceForm : (%,%) -> FPR
++ genericLeftTraceForm (a,b) is defined to be
++ \spad{genericLeftTrace (a*b)}, this defines
++ a symmetric bilinear form on the algebra

genericLeftDiscriminant : () -> FPR
++ genericLeftDiscriminant() is the determinant of the
++ generic left trace forms of all products of basis element,
++ if the generic left trace form is associative, an algebra
++ is separable if the generic left discriminant is invertible,
++ if it is non-zero, there is some ring extension which
++ makes the algebra separable

genericRightTraceForm : (%,%) -> FPR
++ genericRightTraceForm (a,b) is defined to be
++ \spadfun{genericRightTrace (a*b)}, this defines
++ a symmetric bilinear form on the algebra

genericRightDiscriminant : () -> FPR
++ genericRightDiscriminant() is the determinant of the
++ generic left trace forms of all products of basis element,
++ if the generic left trace form is associative, an algebra
++ is separable if the generic left discriminant is invertible,
++ if it is non-zero, there is some ring extension which
++ makes the algebra separable

conditionsForIdempotents : Vector % -> List Polynomial R

```

```

++ conditionsForIdempotents([v1,...,vn]) determines a complete list
++ of polynomial equations for the coefficients of idempotents
++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}

conditionsForIdempotents : () -> List Polynomial R
++ conditionsForIdempotents() determines a complete list
++ of polynomial equations for the coefficients of idempotents
++ with respect to the fixed \spad{R}-module basis

```

=====
GeneralSparseTable
=====

```

Sometimes when working with tables there is a natural value to use as the entry in all but a few cases. The GeneralSparseTable constructor can be used to provide any table type with a default value for entries.

Suppose we launched a fund-raising campaign to raise fifty thousand dollars. To record the contributions, we want a table with strings as keys (for the names) and integer entries (for the amount). In a data base of cash contributions, unless someone has been explicitly entered, it is reasonable to assume they have made a zero dollar contribution.

This creates a keyed access file with default entry 0.

```
patrons: GeneralSparseTable(String, Integer, KeyedAccessFile(Integer), 0) := table() ;
```

Now patrons can be used just as any other table. Here we record two gifts.

```
patrons."Smith" := 10500
```

```
patrons."Jones" := 22000
```

Now let us look up the size of the contributions from Jones and Stingy.

```
patrons."Jones"
```

```
patrons."Stingy"
```

Have we met our seventy thousand dollar goal?

```
reduce(+, entries patrons)
```

So the project is cancelled and we can delete the data base:

```
)system rm -r kaf*.sdata
```

GeneralTriangularSet examples

A domain constructor of the category TriangularSetCategory. The only requirement for a list of polynomials to be a member of such a domain is the following: no polynomial is constant and two distinct

polynomials have distinct main variables. Such a triangular set may not be auto-reduced or consistent. Triangular sets are stored as sorted lists w.r.t. the main variables of their members but they are displayed in reverse order.

GeneralUnivariatePowerSeries examples
=====

```

This is a category of univariate Puiseux series constructed from univariate Laurent series. A Puiseux series is represented by a pair $[r, f(x)]$, where r is a positive rational number and $f(x)$ is a Laurent series. This pair represents the Puiseux series $f(x)^{1/r}$.

graphImage : () -> $
++ graphImage() returns an empty graph with 0 point lists
++ of the domain \spadtype{GraphImage}. A graph image contains
++ the graph data component of a two dimensional viewport.

makeGraphImage : $ -> $
++ makeGraphImage(gi) takes the given graph, \spad{gi} of the
++ domain \spadtype{GraphImage}, and sends it's data to the
++ viewport manager where it waits to be included in a two-dimensional
++ viewport window. \spad{gi} cannot be an empty graph, and it's
++ elements must have been created using the \spadfun{point} or
++ \spadfun{component} functions, not by a previous
++ \spadfun{makeGraphImage}.

makeGraphImage : (L L P) -> $
++ makeGraphImage(llp) returns a graph of the domain
++ \spadtype{GraphImage} which is composed of the points and
++ lines from the list of lists of points, \spad{llp}, with
++ default point size and default point and line colours. The graph
++ data is then sent to the viewport manager where it waits to be
++ included in a two-dimensional viewport window.

makeGraphImage : (L L P,L PAL,L PAL,L PI) -> $
++ makeGraphImage(llp,lpal1,lpal2,lp) returns a graph of the
++ domain \spadtype{GraphImage} which is composed of the points
++ and lines from the list of lists of points, \spad{llp}, whose
++ point colors are indicated by the list of palette colors,
++ \spad{lpal1}, and whose lines are colored according to the list
++ of palette colors, \spad{lpal2}. The paramater lp is a list of
++ integers which denote the size of the data points. The graph
++ data is then sent to the viewport manager where it waits to be
++ included in a two-dimensional viewport window.

```

```

makeGraphImage : (L L P,L PAL,L PAL,L PI,L DROP) -> $
++ makeGraphImage(llp,lpal1,lpal2,lp,lopt) returns a graph of
++ the domain \spadtype{GraphImage} which is composed of the
++ points and lines from the list of lists of points, \spad{llp},
++ whose point colors are indicated by the list of palette colors,
++ \spad{lpal1}, and whose lines are colored according to the list
++ of palette colors, \spad{lpal2}. The parameter lp is a list of
++ integers which denote the size of the data points, and \spad{lopt}
++ is the list of draw command options. The graph data is then sent
++ to the viewport manager where it waits to be included in a
++ two-dimensional viewport window.

pointLists : $ -> L L P
++ pointLists(gi) returns the list of lists of points which compose
++ the given graph, \spad{gi}, of the domain \spadtype{GraphImage}.

key : $ -> I
++ key(gi) returns the process ID of the given graph, \spad{gi},
++ of the domain \spadtype{GraphImage}.

ranges : $ -> RANGEF
++ ranges(gi) returns the list of ranges of the point components from
++ the indicated graph, \spad{gi}, of the domain \spadtype{GraphImage}.

ranges : ($,RANGEF) -> RANGEF
++ ranges(gi,lr) modifies the list of ranges for the given graph,
++ \spad{gi} of the domain \spadtype{GraphImage}, to be that of the
++ list of range segments, \spad{lr}, and returns the new range list
++ for \spad{gi}.

units : $ -> UNITF
++ units(gi) returns the list of unit increments for the x and y
++ axes of the indicated graph, \spad{gi}, of the domain
++ \spadtype{GraphImage}.

units : ($,UNITF) -> UNITF
++ units(gi,lu) modifies the list of unit increments for the x and y
++ axes of the given graph, \spad{gi} of the domain
++ \spadtype{GraphImage}, to be that of the list of unit increments,
++ \spad{lu}, and returns the new list of units for \spad{gi}.

component : ($,L P,PAL,PAL,PI) -> Void
++ component(gi,lp,pal1,pal2,p) sets the components of the
++ graph, \spad{gi} of the domain \spadtype{GraphImage}, to the
++ values given. The point list for \spad{gi} is set to the list
++ \spad{lp}, the color of the points in \spad{lp} is set to
++ the palette color \spad{pal1}, the color of the lines which
++ connect the points \spad{lp} is set to the palette color
++ \spad{pal2}, and the size of the points in \spad{lp} is given
++ by the integer p.

```

```

component : ($,P) -> Void
++ component(gi,pt) modifies the graph \spad{gi} of the domain
++ \spadtype{GraphImage} to contain one point component, \spad{pt}
++ whose point color, line color and point size are determined by
++ the default functions \spadfun{pointColorDefault},
++ \spadfun{lineColorDefault}, and \spadfun{pointSizeDefault}.

component : ($,P,PAL,PAL,PI) -> Void
++ component(gi,pt,pal1,pal2,ps) modifies the graph \spad{gi} of
++ the domain \spadtype{GraphImage} to contain one point component,
++ \spad{pt} whose point color is set to the palette color \spad{pal1},
++ line color is set to the palette color \spad{pal2}, and point
++ size is set to the positive integer \spad{ps}.

appendPoint : ($,P) -> Void
++ appendPoint(gi,pt) appends the point \spad{pt} to the end
++ of the list of points component for the graph, \spad{gi}, which is
++ of the domain \spadtype{GraphImage}.

point : ($,P,PAL) -> Void
++ point(gi,pt,pal) modifies the graph \spad{gi} of the domain
++ \spadtype{GraphImage} to contain one point component, \spad{pt}
++ whose point color is set to be the palette color \spad{pal}, and
++ whose line color and point size are determined by the default
++ functions \spadfun{lineColorDefault} and \spadfun{pointSizeDefault}.

coerce : L L P -> $
++ coerce(llp)
++ component(gi,pt) creates and returns a graph of the domain
++ \spadtype{GraphImage} which is composed of the list of list
++ of points given by \spad{llp}, and whose point colors, line colors
++ and point sizes are determined by the default functions
++ \spadfun{pointColorDefault}, \spadfun{lineColorDefault}, and
++ \spadfun{pointSizeDefault}. The graph data is then sent to the
++ viewport manager where it waits to be included in a two-dimensional
++ viewport window.

coerce : $ -> E
++ coerce(gi) returns the indicated graph, \spad{gi}, of domain
++ \spadtype{GraphImage} as output of the domain \spadtype{OutputForm}.

putColorInfo : (L L P,L PAL) -> L L P
++ putColorInfo(llp,lpal) takes a list of list of points, \spad{llp},
++ and returns the points with their hue and shade components
++ set according to the list of palette colors, \spad{lpal}.

figureUnits : L L P -> UNITSF

```

)abbrev domain GOPT GuessOption
++ Author: Martin Rubey
++ Description:
++ GuessOption is a domain whose elements are various options used
++ by Guess.

GuessOption() : SIG == CODE where

  SIG ==> SetCategory with

    maxDerivative : Union(NonNegativeInteger, "arbitrary") -> %
      ++ maxDerivative(d) specifies the maximum derivative in an algebraic
      ++ differential equation. This option is expressed in the form
      ++ \spad{maxDerivative == d}.

    maxShift : Union(NonNegativeInteger, "arbitrary") -> %
      ++ maxShift(d) specifies the maximum shift in a recurrence
      ++ equation. This option is expressed in the form \spad{maxShift == d}.

    maxSubst : Union(PositiveInteger, "arbitrary") -> %
      ++ maxSubst(d) specifies the maximum degree of the monomial substituted
      ++ into the function we are looking for. That is, if \spad{maxSubst ==
      ++ d}, we look for polynomials such that $p(f(x), f(x^2), \dots,
      ++ f(x^d))=0$. equation. This option is expressed in the form
      ++ \spad{maxSubst == d}.
  
```

```

maxPower : Union(PositiveInteger, "arbitrary") -> %
++ maxPower(d) specifies the maximum degree in an algebraic differential
++ equation. For example, the degree of (f'')^3 f' is 4. maxPower(-1)
++ specifies that the maximum exponent can be arbitrary. This option is
++ expressed in the form \spad{maxPower == d}.

homogeneous : Union(PositiveInteger, Boolean) -> %
++ homogeneous(d) specifies whether we allow only homogeneous algebraic
++ differential equations. This option is expressed in the form
++ \spad{homogeneous == d}. If true, then maxPower must be
++ set, too, and ADEs with constant total degree are allowed.
++ If a PositiveInteger is given, only ADE's with this total degree are
++ allowed.

Somos : Union(PositiveInteger, Boolean) -> %
++ Somos(d) specifies whether we want that the total degree of the
++ differential operators is constant, and equal to d, or maxDerivative
++ if true. If true, maxDerivative must be set, too.

maxLevel : Union(NonNegativeInteger, "arbitrary") -> %
++ maxLevel(d) specifies the maximum number of recursion levels operators
++ guessProduct and guessSum will be applied. This option is expressed in
++ the form \spad{maxLevel == d}.

maxDegree : Union(NonNegativeInteger, "arbitrary") -> %
++ maxDegree(d) specifies the maximum degree of the coefficient
++ polynomials in an algebraic differential equation or a recursion with
++ polynomial coefficients. For rational functions with an exponential
++ term, \spad{maxDegree} bounds the degree of the denominator
++ polynomial.
++ This option is expressed in the form \spad{maxDegree == d}.

maxMixedDegree : NonNegativeInteger -> %
++ maxMixedDegree(d) specifies the maximum q-degree of the coefficient
++ polynomials in a recurrence with polynomial coefficients, in the case
++ of mixed shifts. Although slightly inconsistent, maxMixedDegree(0)
++ specifies that no mixed shifts are allowed. This option is expressed
++ in the form \spad{maxMixedDegree == d}.

allDegrees : Boolean -> %
++ allDegrees(d) specifies whether all possibilities of the degree vector
++ - taking into account maxDegree - should be tried. This is mainly
++ interesting for rational interpolation. This option is expressed in
++ the form \spad{allDegrees == d}.

safety : NonNegativeInteger -> %
++ safety(d) specifies the number of values reserved for testing any
++ solutions found. This option is expressed in the form \spad{safety ==
++ d}.

```

```

check : Union("skip", "MonteCarlo", "deterministic") -> %
++ check(d) specifies how we want to check the solution. If
++ the value is "skip", we return the solutions found by the
++ interpolation routine without checking. If the value is
++ "MonteCarlo", we use a probabilistic check. This option is
++ expressed in the form \spad{check == d}

checkExtraValues : Boolean -> %
++ checkExtraValues(d) specifies whether we want to check the
++ solution beyond the order given by the degree bounds. This
++ option is expressed in the form \spad{checkExtraValues == d}

one : Boolean -> %
++ one(d) specifies whether we are happy with one solution. This option
++ is expressed in the form \spad{one == d}.

debug : Boolean -> %
++ debug(d) specifies whether we want additional output on the
++ progress. This option is expressed in the form \spad{debug == d}.

functionName : Symbol -> %
++ functionName(d) specifies the name of the function given by the
++ algebraic differential equation or recurrence. This option is
++ expressed in the form \spad{functionName == d}.

functionNames : List(Symbol) -> %
++ functionNames(d) specifies the names for the function in
++ algebraic dependence. This option is
++ expressed in the form \spad{functionNames == d}.

variableName : Symbol -> %
++ variableName(d) specifies the variable used in by the algebraic
++ differential equation. This option is expressed in the form
++ \spad{variableName == d}.

indexName : Symbol -> %
++ indexName(d) specifies the index variable used for the formulas. This
++ option is expressed in the form \spad{indexName == d}.

displayKind : Symbol -> %
++ displayKind(d) specifies kind of the result: generating function,
++ recurrence or equation. This option should not be set by the
++ user, but rather by the HP-specification.

option : (List %, Symbol) -> Union(Any, "failed")
++ option(l, option) returns which options are given.

o)show GuessOptionFunctions0

GuessOptionFunctions0 (GOPT0)

— domain GOPT0 GuessOptionFunctions0 —

```

)abbrev domain GOPT0 GuessOptionFunctions0
++ Author: Martin Rubey
++ Description:
++ GuessOptionFunctions0 provides operations that extract the
++ values of options for Guess.

GuessOptionFunctions0() : SIG == CODE where

  LGOPT ==> List GuessOption

  SIG ==> SetCategory with

    maxDerivative : LGOPT -> Union(NonNegativeInteger, "arbitrary")
      ++ maxDerivative returns the specified maxDerivative.

    maxShift : LGOPT -> Union(NonNegativeInteger, "arbitrary")
      ++ maxShift returns the specified maxShift.

    maxSubst : LGOPT -> Union(PositiveInteger, "arbitrary")
      ++ maxSubst returns the specified maxSubst.

    maxPower : LGOPT -> Union(PositiveInteger, "arbitrary")
      ++ maxPower returns the specified maxPower.

    homogeneous : LGOPT -> Union(PositiveInteger, Boolean)
      ++ homogeneous returns whether we allow only homogeneous algebraic

```

```

    ++ differential equations, default being false

Somos : LGOPT -> Union(PositiveInteger, Boolean)
    ++ Somos returns whether we allow only Somos-like operators, default
    ++ being false

maxLevel : LGOPT -> Union(NonNegativeInteger, "arbitrary")
    ++ maxLevel returns the specified maxLevel.

maxDegree : LGOPT -> Union(NonNegativeInteger, "arbitrary")
    ++ maxDegree returns the specified maxDegree.

maxMixedDegree : LGOPT -> NonNegativeInteger
    ++ maxMixedDegree returns the specified maxMixedDegree.

allDegrees : LGOPT -> Boolean
    ++ allDegrees returns whether all possibilities of the degree vector
    ++ should be tried, the default being false.

safety : LGOPT -> NonNegativeInteger
    ++ safety returns the specified safety or 1 as default.

check : LGOPT -> Union("skip", "MonteCarlo", "deterministic")
    ++ check(d) specifies how we want to check the solution. If
    ++ the value is "skip", we return the solutions found by the
    ++ interpolation routine without checking. If the value is
    ++ "MonteCarlo", we use a probabilistic check. The default is
    ++ "deterministic".

checkExtraValues : LGOPT -> Boolean
    ++ checkExtraValues(d) specifies whether we want to check the
    ++ solution beyond the order given by the degree bounds. The
    ++ default is true.

one : LGOPT -> Boolean
    ++ one returns whether we need only one solution, default being true.

functionName : LGOPT -> Symbol
    ++ functionName returns the name of the function given by the algebraic
    ++ differential equation, default being f

variableName : LGOPT -> Symbol
    ++ variableName returns the name of the variable used in by the
    ++ algebraic differential equation, default being x

indexName : LGOPT -> Symbol
    ++ indexName returns the name of the index variable used for the
    ++ formulas, default being n

displayAsGF : LGOPT -> Boolean

```

```

++ displayAsGF specifies whether the result is a generating function
++ or a recurrence. This option should not be set by the user, but rather
++ by the HP-specification, therefore, there is no default.

debug : LGOPT -> Boolean
++ debug returns whether we want additional output on the progress,
++ default being false

checkOptions : LGOPT -> Void
++ checkOptions checks whether the given options are consistent, and
++ yields an error otherwise

=====

Heap examples

=====

The domain Heap(S) implements a priority queue of objects of type S such that the operation extract! removes and returns the maximum element. The implementation represents heaps as flexible arrays The representation and algorithms give complexity of $O(\log(n))$ for insertion and extractions, and $O(n)$ for construction.

Create a heap of five elements:

```

a:Heap INT:= heap [1,2,3,4,5]
               [5,4,2,1,3]

```

Use bag to convert a Bag into a Heap:

```
bag([1,2,3,4,5])$Heap(INT)
[5,4,3,1,2]
```

The operation copy can be used to copy a Heap:

```
c:=copy a
[5,4,2,1,3]
```

Use empty? to check if the heap is empty:

```
empty? a
false
```

Use empty to create a new, empty heap:

```
b:=empty()$(Heap INT)
[]
```

and we can see that the newly created heap is empty:

```
empty? b
true
```

The eq? function compares the reference of one heap to another:

```
eq?(a,c)
false
```

The extract! function removes largest element of the heap:

```
extract! a
5
```

Now extract! elements repeatedly until none are left, collecting the elements in a list.

```
[extract!(h) while not empty?(h)]
[9,7,3,2,- 4,- 7]
Type: List Integer
```

Another way to produce the same result is by defining a heapsort function.

```
heapsort(x) == (empty? x => []; cons(extract!(x),heapsort x))
Type: Void
```

Create another sample heap.

```
h1 := heap [17,-4,9,-11,2,7,-7]
[17,2,9,- 11,- 4,7,- 7]
Type: Heap Integer
```

Apply heapsort to present elements in order.

```
heapsort h1
[17,9,7,2,- 4,- 7,- 11]
Type: List Integer
```

Heaps can be compared with =

```
(a=c)@Boolean
false
```

and ~=

```
(a~=c)
true
```

The inspect function shows the largest element in the heap:

```
inspect a
4
```

The insert! function adds an element to the heap:

```
insert!(9,a)
[9,4,2,1,3]
```

The map function applies a function to every element of the heap and returns a new heap:

```
map(x+>x+10,a)
[19,14,12,11,13]
```

The original heap is unchanged:

```
a
[9,4,2,1,3]
```

The map! function applies a function to every element of the heap and returns the original heap with modifications:

```
map!(x+>x+10,a)
[19,14,12,11,13]
```

The original heap has been modified:

```
a
[19,14,12,11,13]
```

The max function returns the largest element in the heap:

```
max a
19
```

The merge function takes two heaps and creates a new heap with all of the elements:

```
merge(a,c)
[19,14,12,11,13,5,4,2,1,3]
```

Notice that the original heap is unchanged:

```
a
[19,14,12,11,13]
```

The merge! function takes two heaps and modifies the first heap argument to contain all of the elements:

```
merge!(a,c)
[19,14,12,11,13,5,4,2,1,3]
```

Notice that the first argument was modified:

```
a
[19,14,12,11,13,5,4,2,1,3]
```

but the second argument was not:

```
c
[5,4,2,1,3]
```

A new, empty heap can be created with sample:

```
sample()$Heap(INT)
[]
```

The # function gives the size of the heap:

```
#a
10
```

The any? function tests each element against a predicate function and returns true if any pass:

```
any?(x+>=>(x=14),a)
true
```

The every? function tests each element against a predicate function and returns true if they all pass:

```
every?(x+-->(x=11),a)
false
```

The parts function returns a list of the elements in the heap:

```
parts a
[19,14,12,11,13,5,4,2,1,3]
```

The size? predicate compares the size of the heap to a value:

```
size?(a,9)
false
```

The more? predicate asks if the heap size is larger than a value:

```
more?(a,9)
true
```

The less? predicate asks if the heap size is smaller than a value:

```
less?(a,9)
false
```

The members function returns a list of the elements of the heap:

```
members a
[19,14,12,11,13,5,4,2,1,3]
```

The member? predicate asks if an element is in the heap:

```
member?(14,a)
true
```

The count function has two forms, one of which counts the number of copies of an element in the heap:

```
count(14,a)
1
```

The second form of the count function accepts a predicate to test against each member of the heap and counts the number of true results:

```
count(x+-->(x>13),a)
2
```

=====

HexadecimalExpansion

=====

All rationals have repeating hexadecimal expansions. The operation `hex` returns these expansions of type `HexadecimalExpansion`. Operations to access the individual numerals of a hexadecimal expansion can be obtained by converting the value to `RadixExpansion(16)`. More examples of expansions are available in the `DecimalExpansion`, `BinaryExpansion`, and `RadixExpansion`.

This is a hexadecimal expansion of a rational number.

```
r := hex(22/7)
      ---
      3.249
                                     Type: HexadecimalExpansion
```

Arithmetic is exact.

```
r + hex(6/7)
      4
                                     Type: HexadecimalExpansion
```

The period of the expansion can be short or long ...

```
[hex(1/i) for i in 350..354]
      -----
      [0.00BB3EE721A54D88, 0.00BAB6561, 0.00BA2E8, 0.00B9A7862A0FF465879D5F,
      -----
      0.00B92143FA36F5E02E4850FE8DBD78]
                                     Type: List HexadecimalExpansion
```

or very long!

```
hex(1/1007)
      -----
      0.0041149783F0BF2C7D13933192AF6980619EE345E91EC2BB9D5CCA5C071E40926E54E8D
      -----
      DAE24196C0B2F8A0AAD60DBA57F5D4C8536262210C74F1
                                     Type: HexadecimalExpansion
```

These numbers are bona fide algebraic objects.

```
p := hex(1/4)*x**2 + hex(2/3)*x + hex(4/9)
      2      -      ---
      0.4x  + 0.Ax + 0.71C
                                     Type: Polynomial HexadecimalExpansion
```

```
q := D(p, x)
      -
      0.8x + 0.A
                                     Type: Polynomial HexadecimalExpansion
```

```
g := gcd(p, q)
      -
      x + 1.5
                                     Type: Polynomial HexadecimalExpansion
```

package HTMLFORM HTMLFormat

Here I have put some information about 'how to use' and 'the benefits of' this HTML formatter. Also some information for programmers if they want to extend this package.

If you want information about creating output formatters in general then, rather than duplicating content here I refer you to `mathml.spad.pamphlet` containing the `MathMLFormat` domain by Arthur C. Ralfs. This contains useful information for writers of output formatters.

Overview

This package allows users to cut and paste output from the Axiom command line to a HTML page. This output is enabled by typing:

```
)set output html on
```

After this the command line will output html (in addition to other formats that are enabled) and this html code can then be copied and pasted into a HTML document.

The HTML produced is well formed XML, that is, all tags have equivalent closing tags.

Why output to HTML?

In some ways HTMLFormat is a compromise between the standard text output and specialised formats like MathMLFormat. The potential quality is never going to be as good as output to a specialised maths renderer but on the other hand it is a lot better than the clunky fixed width font text output. The quality is not the only issue though, the direct output in any format is unlikely to be exactly what the user wants, so possibly more important than quality is the ability to edit the output.

HTMLFormat has advantages that the other output formats don't, for instance,

- It works with any browser without the need for plugins (as far as I know most computers should have the required fonts)
- Users can easily annotate and add comments using colour, bold, underline and so on.
- Annotations can easily be done with whatever html editor or text editor you are familiar with.
- Edits to the output will cause the width of columns and so on to be automatically adjusted, no need to try to insert spaces to get the superscripts to line up again!
- It is very easy to customise output so, for instance, we can fit a lot of information in a compact space on the page.

Using the formatter

We can cause the command line interpreter to output in html by typing the following:

```
)set output html on
```

After this the command line will output html (in addition to other formats that are enabled) and this html code can then be copied and pasted into an existing HTML document.

If you do not already have an html page to copy the output to then you can create one with a text editor and entering the following:

```
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"
"http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">
<html xmlns="http://www.w3.org/1999/xhtml" >
  <head>
    <title>Enter Your Title Here</title>
  </head>
  <body>
    Copy and paste the output from command line here.
  </body>
</html>
```

Or using any program that will export to html such as OpenOffice.org writer.

Form of the output

HTMLFormat does not try to interpret syntax, for instance in an example like:
 (1) `-> integral(x^x,x)`
 it just takes what OutputForm provides and does not try to replace
`%A` with the bound variable `x`.

Matrix Formatting

A big requirement for me is to fit big matrices on ordinary web pages.

At the moment the default output for a matrix is a grid, however it easy to modify this for a single matrix, or a whole page or whole site by using css (cascading style sheets). For instance we can get a more conventional looking matrix by adding the following style to the top of the page after the `<head>` tag:

```
<style type="text/css">
#matl {border-left-style:solid}
#matr {border-right-style:solid}
#matlt {border-left-style:solid;border-top-style:solid}
#matrt {border-right-style:solid;border-top-style:solid}
#matlb {border-left-style:solid;border-bottom-style:solid}
#matrb {border-right-style:solid;border-bottom-style:solid}
</style>
```

There are many other possibilities, for instance we can generate a matrix with bars either side to indicate a determinant. All we have to do is change the css for the site, page or individual element.

Programmers Guide

This package converts from OutputForm, which is a hierarchical tree structure, to html which uses tags arranged in a hierarchical tree structure. So the package converts from one tree (graph) structure to another.

This conversion is done in two stages using an intermediate Tree String structure. This Tree String structure represents HTML where:

- leafs represents unstructured text
- string in leafs contains the text
- non-leafs represents xml elements
- string in non-leafs represents xml attributes

This is created by traversing `OutputForm` while building up the `Tree String` structure.
 The second stage is to convert the `Tree Structure` to text. All text output is done using:

```
sayTeX$Lisp
```

I have not produced and output to `String` as I don't know a way to append to a long string efficiently and I don't know how to insert carriage- returns into a `String`.

Future Developments

There would be some benefits in creating a `XMLFormat` category which would contain common elements for all xml formatted outputs such as `HTMLFormat`, `MathMLFormat`, `SVGFormat` and `X3DFormat`. However programming effort might be better spent creating a version of `OutputForm` which has better syntax information.

)abbrev domain HTMLFORM HTMLFormat
++ Author: Martin J Baker, Arthur C. Ralfs, Robert S. Sutor
++ Date: January 2010
++ Description:
++ HtmlFormat provides a coercion from OutputForm to html.

HTMLFormat() : SIG == CODE where

  E ==> OutputForm
  I ==> Integer
  L ==> List
  S ==> String

  SIG ==> SetCategory with

    coerce : E -> S
      ++ coerce(o) changes o in the standard output format to html format.
      ++
      ++X coerce(sqrt(3+x)::OutputForm)$HTMLFORM

    coerceS : E -> S
      ++ coerceS(o) changes o in the standard output format to html
      ++ format and displays formatted result.
      ++
      ++X coerceS(sqrt(3+x)::OutputForm)$HTMLFORM

    coerceL : E -> S
      ++ coerceL(o) changes o in the standard output format to html
      ++ format and displays result as one long string.
      ++
      ++X coerceL(sqrt(3+x)::OutputForm)$HTMLFORM

    exprex : E -> S
      ++ exprex(o) converts \spadtype{OutputForm} to \spadtype{String}
      ++
      ++X exprex(sqrt(3+x)::OutputForm)$HTMLFORM

    display : S -> Void
      ++ display(o) prints the string returned by coerce.
      ++
      ++X display(coerce(sqrt(3+x)::OutputForm)$HTMLFORM)$HTMLFORM

-- this one doesn't have the leading integer
-- {{+}{{ZAG}{1}{7}}{{ZAG}{1}{15}}{{ZAG}{1}{1}}{{ZAG}{1}{25}}
-- {{ZAG}{1}{1}}{{ZAG}{1}{7}}{{ZAG}{1}{4}}}
--
-- ex 3. continuedFraction(3,repeating [1], repeating [3,6])
-- {{+}{3}{{ZAG}{1}{3}}{{ZAG}{1}{6}}{{ZAG}{1}{3}}{{ZAG}{1}{6}}
-- {{ZAG}{1}{3}}{{ZAG}{1}{6}}{{ZAG}{1}{3}}{{ZAG}{1}{6}}
-- {{ZAG}{1}{3}}{{ZAG}{1}{6}}{...}}
--
-- In each of these examples the args list consists of the terms
-- following the '+' op
-- so the first arg could be a "ZAG" or something
-- else, but the second arg looks like it has to be "ZAG", so maybe
-- test for #args > 1 and args.2 contains "ZAG".
-- Note that since the resulting tables are nested we need
-- to handle the whole continued fraction at once, we can't
-- just look, for example, {{ZAG}{1}{6}}
--
-- we will assume that the font starts at 16px and reduce it by 4
-- <span style='font-size:16px'>outer zag</span>
-- <span style='font-size:14px'>next zag</span>
-- <span style='font-size:12px'>next zag</span>

=====
MultivariatePolynomial
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
GeneralDistributedMultivariatePolynomial
=====

```

DistributedMultivariatePolynomial which is abbreviated as DMP and HomogeneousDistributedMultivariatePolynomial, which is abbreviated as HDMP, are very similar to MultivariatePolynomial except that they are represented and displayed in a non-recursive manner.

```

(d1,d2,d3) : DMP([z,y,x],FRAC INT)
              Type: Void

```

The constructor DMP orders its monomials lexicographically while HDMP orders them by total order refined by reverse lexicographic order.

```

d1 := -4*z + 4*y**2*x + 16*x**2 + 1
      2      2
      - 4z + 4y x + 16x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

```

d2 := 2*z*y**2 + 4*x + 1
      2
      2z y + 4x + 1
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

```

d3 := 2*z*x**2 - 2*y**2 - x
      2      2
      2z x - 2y - x
      Type: DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

```

These constructors are mostly used in Groebner basis calculations.

```

groebner [d1,d2,d3]

```

$$\begin{aligned}
& [z - \frac{1568}{2745}x^6 - \frac{1264}{305}x^5 + \frac{6}{305}x^4 + \frac{182}{549}x^3 - \frac{2047}{610}x^2 - \frac{103}{2745}x - \frac{2857}{10980}, \\
& y + \frac{2}{2745}x^{112} - \frac{6}{305}x^{84} - \frac{5}{305}x^{1264} - \frac{4}{549}x^{13} + \frac{3}{305}x^{84} + \frac{2}{2745}x^{1772} + \frac{2}{2745}, \\
& x^7 + \frac{29}{4}x^6 - \frac{17}{8}x^4 - \frac{11}{8}x^3 + \frac{1}{32}x^2 + \frac{15}{16}x + \frac{1}{4}]
\end{aligned}$$

Type: List DistributedMultivariatePolynomial([z,y,x],Fraction Integer)

(n1,n2,n3) : HDMP([z,y,x],FRAC INT)
Type: Void

n1 := d1
 $4y^2x^2 + 16x^2 - 4z + 1$
Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

n2 := d2
 $2z^2y + 4x + 1$
Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

n3 := d3
 $2z^2x^2 - 2y^2 - x$
Type: HomogeneousDistributedMultivariatePolynomial([z,y,x],Fraction Integer)

Note that we get a different Groebner basis when we use the HDMP polynomials, as expected.

groebner [n1,n2,n3]

$$\begin{aligned}
& [y^4 + 2x^3 - \frac{3}{2}x^2 + \frac{1}{2}z - \frac{1}{8}, x^4 + \frac{29}{4}x^3 - \frac{1}{8}y^2 - \frac{7}{4}zx - \frac{9}{16}x - \frac{1}{4}, \\
& z^2y^2 + 2x^2 + \frac{1}{2}, y^2x + 4x^2 - z + \frac{1}{4}, z^2x^2 - y^2 - \frac{1}{2}x, \\
& z^2 - 4y^2 + 2x^2 - \frac{1}{4}z - \frac{3}{2}x]
\end{aligned}$$

Type: List HomogeneousDistributedMultivariatePolynomial([z,y,x],
Fraction Integer)

GeneralDistributedMultivariatePolynomial is somewhat more flexible in the sense that as well as accepting a list of variables to specify the variable ordering, it also takes a predicate on exponent vectors to specify the term ordering. With this polynomial type the user can experiment with the effect of using completely arbitrary term orderings.

This flexibility is mostly important for algorithms such as Groebner basis calculations which can be very sensitive to term ordering.

HyperellipticFiniteDivisor examples

=====

This domains implements finite rational divisors on an hyperelliptic curve, that is finite formal sums $\sum(n * P)$ where the n 's are integers and the P 's are finite rational points on the curve.

The equation of the curve must be $y^2 = f(x)$ and f must have odd degree.

=====
IndexedFlexibleArray examples
=====

```

A FlexibleArray is the notion of an array intended to allow for growth at the end only. Hence the following efficient operations

```

  append(x,a) meaning append item x at the end of the array a
  delete(a,n)} meaning delete the last item from the array a

```

Flexible arrays support the other operations inherited from ExtensibleLinearAggregate. However, these are not efficient.

Flexible arrays combine the $O(1)$ access time property of arrays with growing and shrinking at the end in $O(1)$ (average) time. This is done by using an ordinary array which may have zero or more empty slots at the end. When the array becomes full it is copied

into a new larger (50% larger) array. Conversely, when the array becomes less than 1/2 full, it is copied into a smaller array. Flexible arrays provide for an efficient implementation of many data structures in particular heaps, stacks and sets.

++ \spad{delete(a,n)} meaning delete the last item from the array \spad{a}\br
++ Flexible arrays support the other operations inherited from
++ \spadtype{ExtensibleLinearAggregate}. However, these are not efficient.
++ Flexible arrays combine the \spad{0(1)} access time property of arrays
++ with growing and shrinking at the end in \spad{0(1)} (average) time.
++ This is done by using an ordinary array which may have zero or more
++ empty slots at the end. When the array becomes full it is copied
++ into a new larger (50% larger) array. Conversely, when the array
++ becomes less than 1/2 full, it is copied into a smaller array.
++ Flexible arrays provide for an efficient implementation of many
++ data structures in particular heaps, stacks and sets.

=====
 IndexedList examples
 =====

IndexedList is a basic implementation of the functions in
 ListAggregate, often using functions in the underlying LISP

system. The second parameter to the constructor (`mn`) is the beginning index of the list. That is, if `l` is a list, then `elt(l,mn)` is the first value. This constructor is probably best viewed as the implementation of singly-linked lists that are addressable by index rather than as a mere wrapper for LISP lists.

IndexedMatrix examples

=====

An IndexedMatrix is a matrix where the minimal row and column indices are parameters of the type. The domains Row and Col are both IndexedVectors.

The index of the 'first' row may be obtained by calling the function `minRowIndex`. The index of the 'first' column may be obtained by calling the function `minColIndex`. The index of the first element of a 'Row' is the same as the index of the first column in a matrix and vice versa.

domain IARRAY2 IndexedTwoDimensionalArray

An IndexedTwoDimensionalArray is a 2-dimensional array where the minimal row and column indices are parameters of the type. Rows and columns are returned as IndexedOneDimensionalArray's with minimal indices matching those of the IndexedTwoDimensionalArray. The index of the 'first' row may be obtained by calling the function 'minRowIndex'. The index of the 'first' column may be obtained by calling the function 'minColIndex'. The index of the first element of a 'Row' is the same as the index of the first column in an array and vice versa.

— domain IPADIC InnerPAdicInteger —

```

)abbrev domain IPADIC InnerPAdicInteger
++ Author: Clifton J. Williamson
++ Date Created: 20 August 1989
++ Date Last Updated: 15 May 1990
++ Description:
++ This domain implements  $\mathbb{Z}_p$ , the p-adic completion of the integers.
++ This is an internal domain.

```

```

)abbrev domain ISUPS InnerSparseUnivariatePowerSeries
++ Author: Clifton J. Williamson
++ Date Created: 28 October 1994
++ Date Last Updated: 9 March 1995
++ Description:
++ InnerSparseUnivariatePowerSeries is an internal domain
++ used for creating sparse Taylor and Laurent series.

InnerSparseUnivariatePowerSeries(Coef) : SIG == CODE where
  Coef  : Ring

  B      ==> Boolean
  COM    ==> OrderedCompletion Integer
  I      ==> Integer
  L      ==> List
  NNI    ==> NonNegativeInteger
  OUT    ==> OutputForm
  PI     ==> PositiveInteger
  REF    ==> Reference OrderedCompletion Integer
  RN     ==> Fraction Integer
  Term   ==> Record(k:Integer,c:Coef)
  SG     ==> String

```

```

ST ==> Stream Term

SIG ==> UnivariatePowerSeriesCategory(Coef,Integer) with

makeSeries: (REF,ST) -> %
  ++ makeSeries(refer,str) creates a power series from the reference
  ++ \spad{refer} and the stream \spad{str}.

getRef: % -> REF
  ++ getRef(f) returns a reference containing the order to which the
  ++ terms of f have been computed.

getStream: % -> ST
  ++ getStream(f) returns the stream of terms representing the series f.

series: ST -> %
  ++ series(st) creates a series from a stream of non-zero terms,
  ++ where a term is an exponent-coefficient pair. The terms in the
  ++ stream should be ordered by increasing order of exponents.

monomial?: % -> B
  ++ monomial?(f) tests if f is a single monomial.

multiplyCoefficients: (I -> Coef,%) -> %
  ++ multiplyCoefficients(fn,f) returns the series
  ++ \spad{sum(fn(n) * an * x^n,n = n0..)},
  ++ where f is the series \spad{sum(an * x^n,n = n0..)}.

iExquo: (%,%B) -> Union(%, "failed")
  ++ iExquo(f,g,taylor?) is the quotient of the power series f and g.
  ++ If \spad{taylor?} is \spad{true}, then we must have
  ++ \spad{order(f) >= order(g)}.

taylorQuoByVar: % -> %
  ++ taylorQuoByVar(a0 + a1 x + a2 x**2 + ...)
  ++ returns \spad{a1 + a2 x + a3 x**2 + ...}

iCompose: (%,%) -> %
  ++ iCompose(f,g) returns \spad{f(g(x))}. This is an internal function
  ++ which should only be called for Taylor series \spad{f(x)} and
  ++ \spad{g(x)} such that the constant coefficient of \spad{g(x)} is zero.

seriesToOutputForm: (ST,REF,Symbol,Coef,RN) -> OutputForm
  ++ seriesToOutputForm(st,refer,var,cen,r) prints the series
  ++ \spad{f((var - cen)^r)}.

if Coef has Algebra Fraction Integer then

integrate : % -> %
  ++ integrate(f(x)) returns an anti-derivative of the power series

```

```

++ \spad{f(x)} with constant coefficient 0.
++ Warning: function does not check for a term of degree -1.

cPower : (% , Coef) -> %
++ cPower(f,r) computes \spad{f^r}, where f has constant coefficient 1.
++ For use when the coefficient ring is commutative.

cRationalPower : (% , RN) -> %
++ cRationalPower(f,r) computes \spad{f^r}.
++ For use when the coefficient ring is commutative.

cExp : % -> %
++ cExp(f) computes the exponential of the power series f.
++ For use when the coefficient ring is commutative.

cLog : % -> %
++ cLog(f) computes the logarithm of the power series f.
++ For use when the coefficient ring is commutative.

cSin : % -> %
++ cSin(f) computes the sine of the power series f.
++ For use when the coefficient ring is commutative.

cCos : % -> %
++ cCos(f) computes the cosine of the power series f.
++ For use when the coefficient ring is commutative.

cTan : % -> %
++ cTan(f) computes the tangent of the power series f.
++ For use when the coefficient ring is commutative.

cCot : % -> %
++ cCot(f) computes the cotangent of the power series f.
++ For use when the coefficient ring is commutative.

cSec : % -> %
++ cSec(f) computes the secant of the power series f.
++ For use when the coefficient ring is commutative.

cCsc : % -> %
++ cCsc(f) computes the cosecant of the power series f.
++ For use when the coefficient ring is commutative.

cAsin : % -> %
++ cAsin(f) computes the arcsine of the power series f.
++ For use when the coefficient ring is commutative.

cAcos : % -> %

InnerTaylorSeries examples

=====

Internal package for dense Taylor series. This is an internal Taylor series type in which Taylor series are represented by a Stream of Ring elements. For univariate series, the Stream elements are the Taylor coefficients. For multivariate series, the n-th Stream element is a form of degree n in the power series variables.

)abbrev domain ITAYLOR InnerTaylorSeries
++ Author: Clifton J. Williamson
++ Date Created: 21 December 1989
++ Date Last Updated: 25 February 1989
++ Description:
++ Internal package for dense Taylor series.
  
```

```

++ This is an internal Taylor series type in which Taylor series
++ are represented by a \spadtype{Stream} of \spadtype{Ring} elements.
++ For univariate series, the \spad{Stream} elements are the Taylor
++ coefficients. For multivariate series, the \spad{n}th Stream element
++ is a form of degree n in the power series variables.

```

```

InnerTaylorSeries(Coef) : SIG == CODE where
  Coef : Ring

```

```

I ==> Integer
NNI ==> NonNegativeInteger
ST ==> Stream Coef
STT ==> StreamTaylorSeriesOperations Coef

```

```

SIG ==> Ring with

```

```

coefficients : % -> Stream Coef
  ++\spad{coefficients(x)} returns a stream of ring elements.
  ++ When x is a univariate series, this is a stream of Taylor
  ++ coefficients. When x is a multivariate series, the
  ++ \spad{n}th element of the stream is a form of
  ++ degree n in the power series variables.

```

```

series : Stream Coef -> %
  ++\spad{series(s)} creates a power series from a stream of
  ++ ring elements.
  ++ For univariate series types, the stream s should be a stream
  ++ of Taylor coefficients. For multivariate series types, the
  ++ stream s should be a stream of forms the \spad{n}th element
  ++ of which is a
  ++ form of degree n in the power series variables.

```

```

pole? : % -> Boolean
  ++\spad{pole?(x)} tests if the series x has a pole.
  ++ Note: this is false when x is a Taylor series.

```

```

order : % -> NNI
  ++\spad{order(x)} returns the order of a power series x,
  ++ that is, the degree of the first non-zero term of the series.

```

```

order : (% , NNI) -> NNI
  ++\spad{order(x,n)} returns the minimum of n and the order of x.

```

```

"*" : (Coef, %) -> %
  ++\spad{c*x} returns the product of c and the series x.

```

```

"*" : (% , Coef) -> %
  ++\spad{x*c} returns the product of c and the series x.

```

```

"*" : (% , Integer) -> %

```

```

++\spad{x*i} returns the product of integer i and the series x.

)abbrev domain INFORM InputForm
++ Author: Manuel Bronstein
++ Date Last Updated: 19 April 1991
++ Description:
++ Domain of parsed forms which can be passed to the interpreter.
++ This is also the interface between algebra code and facilities
++ in the interpreter.

--)boot $noSubsumption := true

InputForm() : SIG == CODE where

  SIG ==> Join(
    SExpressionCategory(String,Symbol,Integer,DoubleFloat,OutputForm),
    ConvertibleTo SExpression) with

  interpret: % -> Any
    ++ interpret(f) passes f to the interpreter.

  convert : SExpression -> %
    ++ convert(s) makes s into an input form.

  binary : (% , List %) -> %
  
```

```

++ \spad{binary(op, [a1,...,an])} returns the input form
++ corresponding to \spad{a1 op a2 op ... op an}.
++
++X a:=[1,2,3]::List(InputForm)
++X binary(_+::InputForm,a)

function : (% , List Symbol, Symbol) -> %
++ \spad{function(code, [x1,...,xn], f)} returns the input form
++ corresponding to \spad{f(x1,...,xn) == code}.

lambda : (% , List Symbol) -> %
++ \spad{lambda(code, [x1,...,xn])} returns the input form
++ corresponding to \spad{(x1,...,xn) +-> code} if \spad{n > 1},
++ or to \spad{x1 +-> code} if \spad{n = 1}.

"+" : (% , %) -> %
++ \spad{a + b} returns the input form corresponding to \spad{a + b}.

"*" : (% , %) -> %
++ \spad{a * b} returns the input form corresponding to \spad{a * b}.

"/" : (% , %) -> %
++ \spad{a / b} returns the input form corresponding to \spad{a / b}.

"*)" : (% , NonNegativeInteger) -> %
++ \spad{a ** b} returns the input form corresponding to \spad{a ** b}.

"*)" : (% , Integer) -> %
++ \spad{a ** b} returns the input form corresponding to \spad{a ** b}.

0 : constant -> %
++ \spad{0} returns the input form corresponding to 0.

1 : constant -> %
++ \spad{1} returns the input form corresponding to 1.

flatten : % -> %
++ flatten(s) returns an input form corresponding to s with
++ all the nested operations flattened to triples using new
++ local variables.
++ If s is a piece of code, this speeds up
++ the compilation tremendously later on.

unparse : % -> String
++ unparse(f) returns a string s such that the parser
++ would transform s to f.
++ Error: if f is not the parsed form of a string.

parse : String -> %
++ parse(s) is the inverse of unparse. It parses a string to InputForm.

```

```

declare : List % -> Symbol
  ++ declare(t) returns a name f such that f has been
  ++ declared to the interpreter to be of type t, but has
  ++ not been assigned a value yet.
  ++ Note: t should be created as \spad{devaluate(T)$Lisp} where T is the
  ++ actual type of f (this hack is required for the case where
  ++ T is a mapping type).

compile : (Symbol, List %) -> Symbol
  ++ \spad{compile(f, [t1,...,tn])} forces the interpreter to compile
  ++ the function f with signature \spad{(t1,...,tn) -> ?}.
  ++ returns the symbol f if successful.
  ++ Error: if f was not defined beforehand in the interpreter,
  ++ or if the ti's are not valid types, or if the compiler fails.

=====

Integer examples

=====

Axiom provides many operations for manipulating arbitrary precision integers. In this section we will show some of those that come from Integer itself plus some that are implemented in other packages.

\subsection{Basic Functions}

The size of an integer in Axiom is only limited by the amount of computer storage you have available. The usual arithmetic operations are available.

```

2**(5678 - 4856 + 2 * 17)
4804810770435008147181540925125924391239526139871682263473855610088084200076_
308293086342527091412083743074572278211496076276922026433435687527334980249_
539302425425230458177649495442143929053063884787051467457680738771416988598_
15495632935288783334250628775936
Type: PositiveInteger

```

There are a number of ways of working with the sign of an integer.
Let's use this x as an example.

```

x := -101
- 101
Type: Integer

```

First of all, there is the absolute value function.

```

abs(x)
101
Type: PositiveInteger

```

The sign operation returns -1 if its argument is negative, 0 if zero
and 1 if positive.

```

sign(x)
- 1
Type: Integer

```

You can determine if an integer is negative in several other ways.

```

x < 0
true
Type: Boolean

```

```

x <= -1
true
Type: Boolean

```

```

negative?(x)
true
Type: Boolean

```

Similarly, you can find out if it is positive.

```

x > 0
false
Type: Boolean

```

```

x >= 1
false
Type: Boolean

```

```
positive?(x)
false
```

Type: Boolean

This is the recommended way of determining whether an integer is zero.

```
zero?(x)
false
```

Type: Boolean

Use the zero? operation whenever you are testing any mathematical object for equality with zero. This is usually more efficient than using = (think of matrices: it is easier to tell if a matrix is zero by just checking term by term than constructing another "zero" matrix and comparing the two matrices term by term) and also avoids the problem that = is usually used for creating equations.

This is the recommended way of determining whether an integer is equal to one.

```
one?(x)
false
```

Type: Boolean

This syntax is used to test equality using =. It says that you want a Boolean (true or false) answer rather than an equation.

```
(x = -101)@Boolean
true
```

Type: Boolean

The operations odd? and even? determine whether an integer is odd or even, respectively. They each return a Boolean object.

```
odd?(x)
true
```

Type: Boolean

```
even?(x)
false
```

Type: Boolean

The operation gcd computes the greatest common divisor of two integers.

```
gcd(56788,43688)
4
```

Type: PositiveInteger

The operation lcm computes their least common multiple.

```
lcm(56788,43688)
620238536
```

Type: PositiveInteger

To determine the maximum of two integers, use max.

```
max(678,567)
678
```

Type: PositiveInteger

To determine the minimum, use min.

```
min(678,567)
567
```

Type: PositiveInteger

The reduce operation is used to extend binary operations to more than two arguments. For example, you can use reduce to find the maximum integer in a list or compute the least common multiple of all integers in the list.

```
reduce(max,[2,45,-89,78,100,-45])
100
```

Type: PositiveInteger

```
reduce(min,[2,45,-89,78,100,-45])
- 89
```

Type: Integer

```
reduce(gcd,[2,45,-89,78,100,-45])
1
```

Type: PositiveInteger

```
reduce(lcm,[2,45,-89,78,100,-45])
1041300
```

Type: PositiveInteger

The infix operator "/" is not used to compute the quotient of integers. Rather, it is used to create rational numbers as described in Fraction.

```
13 / 4
13
--
4
```

Type: Fraction Integer

The infix operation quo computes the integer quotient.

```
13 quo 4
```

```
3
```

```
Type: PositiveInteger
```

The infix operation `rem` computes the integer remainder.

```
13 rem 4
1
```

```
Type: PositiveInteger
```

One integer is evenly divisible by another if the remainder is zero.
The operation `exquo` can also be used.

```
zero?(167604736446952 rem 2003644)
true
```

```
Type: Boolean
```

The operation `divide` returns a record of the quotient and remainder
and thus is more efficient when both are needed.

```
d := divide(13,4)
[quotient= 3,remainder= 1]
Type: Record(quotient: Integer,remainder: Integer)
```

```
d.quotient
3
```

```
Type: PositiveInteger
```

See help on Records for details on Records.

```
d.remainder
1
```

```
Type: PositiveInteger
```

```
=====
Primes and Factorization
=====
```

Use the operation `factor` to factor integers. It returns an object of
type `Factored Integer`.

```
factor 102400
12 2
2 5
```

```
Type: Factored Integer
```

The operation `prime?` returns true or false depending on whether its
argument is a prime.

```
prime? 7
true
```

Type: Boolean

```
prime? 8
false
```

Type: Boolean

The operation `nextPrime` returns the least prime number greater than its argument.

```
nextPrime 100
101
```

Type: PositiveInteger

The operation `prevPrime` returns the greatest prime number less than its argument.

```
prevPrime 100
97
```

Type: PositiveInteger

To compute all primes between two integers (inclusively), use the operation `primes`.

```
primes(100,175)
[173,167,163,157,151,149,139,137,131,127,113,109,107,103,101]
```

Type: List Integer

You might sometimes want to see the factorization of an integer when it is considered a Gaussian integer.

```
factor(2 :: Complex Integer)
2
- %i (1 + %i)
```

Type: Factored Complex Integer

=====

Some Number Theoretic Functions

=====

Axiom provides several number theoretic operations for integers.

The operation `fibonacci` computes the Fibonacci numbers. The algorithm has running time $O(\log^3 n)$ for argument n .

```
[fibonacci(k) for k in 0..]
[0,1,1,2,3,5,8,13,21,34,...]
```

Type: Stream Integer

The operation `legendre` computes the Legendre symbol for its two integer arguments where the second one is prime. If you know the second argument

to be prime, use `jacobi` instead where no check is made.

```
[legendre(i,11) for i in 0..10]
[0,1,- 1,1,1,1,- 1,- 1,- 1,1,- 1]
Type: List Integer
```

The operation `jacobi` computes the Jacobi symbol for its two integer arguments. By convention, 0 is returned if the greatest common divisor of the numerator and denominator is not 1.

```
[jacobi(i,15) for i in 0..9]
[0,1,1,0,1,0,0,- 1,1,0]
Type: List Integer
```

The operation `eulerPhi` computes the values of Euler's ϕ -function where $\phi(n)$ equals the number of positive integers less than or equal to n that are relatively prime to the positive integer n .

```
[eulerPhi i for i in 1..]
[1,1,2,2,4,2,6,4,6,4,...]
Type: Stream Integer
```

The operation `moebiusMu` computes the Moebius μ function.

```
[moebiusMu i for i in 1..]
[1,- 1,- 1,0,- 1,1,- 1,0,0,1,...]
Type: Stream Integer
```

```

)abbrev domain INT Integer
++ Author: Mark Botch
++ References:
++ Corl00 According to Abramowitz and Stegun or arccoth needn't be Uncouth
++ Fate01a A Critique of OpenMath and Thoughts on Encoding Mathematics
++ Description:
++ \spadtype{Integer} provides the domain of arbitrary precision integers.

Integer() : SIG == CODE where

  SIG ==> Join(IntegerNumberSystem, ConvertibleTo String, OpenMath) with

    random : % -> %
      ++ random(n) returns a random integer from 0 to \spad{n-1}.

    canonical
      ++ mathematical equality is data structure equality.

    canonicalsClosed
      ++ two positives multiply to give positive.

    noetherian
      ++ ascending chain condition on ideals.

    infinite
      ++ nextItem never returns "failed".

— IntegrationResult.help —

IntegrationResult examples

The result of a transcendental integration.

If a function f has an elementary integral g , then g can be written in the form

$$g = h + c_1 \log(u_1) + c_2 \log(u_2) + \dots + c_n \log(u_n)$$

where h , which is in the same field than f , is called the rational part of the integral, and

$$c_1 \log(u_1) + \dots + c_n \log(u_n)$$

is called the logarithmic part of the integral. This domain manipulates integrals represented in that form, by keeping both parts separately. The logs are not explicitly computed.

=====
Kernel examples
=====

```

A kernel is a symbolic function application (such as $\sin(x+y)$) or a symbol (such as x). More precisely, a non-symbol kernel over a set S is an operator applied to a given list of arguments from S . The operator has type `BasicOperator` and the kernel object is usually part of an `Expression` object.

Kernels are created implicitly for you when you create expressions.

```

x :: Expression Integer
x
                                     Type: Expression Integer

```

You can directly create a "symbol" kernel by using the kernel operation.

```

kernel x
x
                                     Type: Kernel Expression Integer

```

This expression has two different kernels.

```

sin(x) + cos(x)
sin(x) + cos(x)
                                     Type: Expression Integer

```

The operator `kernels` returns a list of the kernels in an object of type `Expression`.

This expression also has two different kernels.

An expression need not contain any kernels.

Kernels can be nested. Use `height` to determine the nesting depth.

```
height mainKernel(sin cos (tan x + sin x))
4
Type: PositiveInteger
```

Use the operator operation to extract the operator component of the kernel. The operator has type BasicOperator.

```
operator mainKernel(sin cos (tan x + sin x))
sin
Type: BasicOperator
```

Use the name operation to extract the name of the operator component of the kernel. The name has type Symbol. This is really just a shortcut for a two-step process of extracting the operator and then calling name on the operator.

```
name mainKernel(sin cos (tan x + sin x))
sin
Type: Symbol
```

Axiom knows about functions such as sin, cos and so on and can make kernels and then expressions using them. To create a kernel and expression using an arbitrary operator, use operator.

Now f can be used to create symbolic function applications.

```
f := operator 'f
f
Type: BasicOperator

e := f(x, y, 10)
f(x,y,10)
Type: Expression Integer
```

Use the is? operation to learn if the operator component of a kernel is equal to a given operator.

```
is?(e, f)
true
Type: Boolean
```

You can also use a symbol or a string as the second argument to is?.

```
is?(e, 'f)
true
Type: Boolean
```

Use the argument operation to get a list containing the argument component of a kernel.

```
argument mainKernel e
[x,y,10]
Type: List Expression Integer
```

Conceptually, an object of type `Expression` can be thought of a quotient of multivariate polynomials, where the "variables" are kernels. The arguments of the kernels are again expressions and so the structure recurses. See `Expression` for examples of using kernels to take apart expression objects.

— domain `KERNEL` `Kernel` —

```

)abbrev domain KERNEL Kernel
++ Author: Manuel Bronstein
++ Date Created: 22 March 1988
++ Date Last Updated: 10 August 1994
++ Description:
++ A kernel over a set S is an operator applied to a given list

```

++ of arguments from S.

Kernel(S) : SIG == CODE where
S : OrderedSet

O ==> OutputForm
N ==> NonNegativeInteger
OP ==> BasicOperator
SYMBOL ==> "%symbol"
PMPRED ==> "%pmpredicate"
PMOPT ==> "%pmoptional"
PMMULT ==> "%pmmultiple"
PMCONST ==> "%pmconstant"
SPECIALDISP ==> "%specialDisp"
SPECIALEQUAL ==> "%specialEqual"
SPECIALINPUT ==> "%specialInput"

SIG ==> Join(CachableSet, Patternable S) with

name : % -> Symbol
++ name(op(a1,...,an)) returns the name of op.

operator : % -> OP
++ operator(op(a1,...,an)) returns the operator op.

argument : % -> List S
++ argument(op(a1,...,an)) returns \spad{[a1,...,an]}.

height : % -> N
++ height(k) returns the nesting level of k.

kernel : (OP, List S, N) -> %
++ kernel(op, [a1,...,an], m) returns the kernel \spad{op(a1,...,an)}
++ of nesting level m.
++ Error: if op is k-ary for some k not equal to m.

kernel : Symbol -> %
++ kernel(x) returns x viewed as a kernel.

symbolIfCan : % -> Union(Symbol, "failed")
++ symbolIfCan(k) returns k viewed as a symbol if k is a symbol, and
++ "failed" otherwise.

is? : (% , OP) -> Boolean
++ is?(op(a1,...,an), f) tests if op = f.

is? : (% , Symbol) -> Boolean
++ is?(op(a1,...,an), s) tests if the name of op is s.

if S has ConvertibleTo InputForm then ConvertibleTo InputForm

```

=====

KeyedAccessFile examples

=====

The domain KeyedAccessFile(S) provides files which can be used as associative tables. Data values are stored in these files and can be retrieved according to their keys. The keys must be strings so this type behaves very much like the StringTable(S) domain. The difference is that keyed access files reside in secondary storage while string tables are kept in memory.

Before a keyed access file can be used, it must first be opened. A new file can be created by opening it for output.

```
ey: KeyedAccessFile(Integer) := open("editor.year", "output")
```

Just as for vectors, tables or lists, values are saved in a keyed access file by setting elements.

```
ey."Char" := 1986
```

```
ey."Caviness" := 1985
```

```
ey."Fitch" := 1984
```

Values are retrieved using application, in any of its syntactic forms.

```
ey."Char"
```

```
ey("Char")
```

```
ey "Char"
```

Attempting to retrieve a non-existent element in this way causes an error. If it is not known whether a key exists, you should use the search operation.

```
search("Char", ey)
```

```
search("Smith", ey)
```

When an entry is no longer needed, it can be removed from the file.

```
remove!("Char", ey)
```

The keys operation returns a list of all the keys for a given file.

```
keys ey
```

The # operation gives the number of entries.

```
#ey
```

The table view of keyed access files provides safe operations. That is, if the Axiom program is terminated between file operations, the file is left in a consistent, current state. This means, however, that the operations are somewhat costly. For example, after each update the file is closed.

Here we add several more items to the file, then check its contents.

```
KE := Record(key: String, entry: Integer)
```

```
reopen!(ey, "output")
```

If many items are to be added to a file at the same time, then it is more efficient to use the write operation.

```
write!(ey, ["van Hulzen", 1983]$KE)
```

```
write!(ey, ["Calmet", 1982]$KE)
```

```
write!(ey, ["Wang", 1981]$KE)
```

```
close! ey
```

The read operation is also available from the file view, but it

returns elements in a random order. It is generally clearer and more efficient to use the `keys` operation and to extract elements by key.

```
keys ey
```

```
members ey
```

```

— domain KAFfile KeyedAccessFile —

```

)abbrev domain KAFfile KeyedAccessFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain allows a random access file to be viewed both as a table
++ and as a file object. The KeyedAccessFile format is a directory
++ containing a single file called ‘‘index.kaf’’. This file is a random
++ access file. The first thing in the file is an integer which is the
++ byte offset of an association list (the dictionary) at the end of
++ the file. The association list is of the form
++ ((key . byteoffset) (key . byteoffset)...)
++ where the byte offset is the number of bytes from the beginning of
++ the file. This offset contains an s-expression for the value of the key.

KeyedAccessFile(Entry) : SIG == CODE where
  Entry : SetCategory

  Name ==> FileName
  Key   ==> String

  SIG ==> Join(FileCategory(Name, Record(key: Key, entry: Entry)),
    TableAggregate(Key, Entry)) with

    finiteAggregate

  pack_! : % -> %
    ++ pack!(f) reorganizes the file f on disk to recover
    ++ unused space.

=====

Library examples

=====

The Library domain provides a simple way to store Axiom values in a file. This domain is similar to KeyedAccessFile but fewer declarations are needed and items of different types can be saved together in the same file.

To create a library, you supply a file name.

```
stuff := library "Neat.stuff"
```

Now values can be saved by key in the file. The keys should be mnemonic, just as the field names are for records. They can be given either as strings or symbols.

```

stuff.int := 32**2

stuff."poly" := x**2 + 1

stuff.str := "Hello"

```

You obtain the set of available keys using the keys operation.

```
keys stuff
```

You extract values by giving the desired key in this way.

```
stuff.poly  
  
stuff("poly")
```

When the file is no longer needed, you should remove it from the file system.

```
)system rm -rf Neat.stuff
```

)abbrev domain LIB Library
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides a simple way to save values in files.

Library() : SIG == CODE where

SIG ==> TableAggregate(String, Any) with

library : FileName -> %
++ library(ln) creates a new library file.

pack_! : % -> %
++ pack!(f) reorganizes the file f on disk to recover
++ unused space.

elt : (%, Symbol) -> Any
++ elt(lib,k) or lib.k extracts the value corresponding to
++ the key \spad{k} from the library \spad{lib}.

setelt : (%, Symbol, Any) -> Any
++ \spad{lib.k := v} saves the value \spad{v} in the library
++ \spad{lib}. It can later be extracted using the key \spad{k}.

close_! : % -> %
++ close!(f) returns the library f closed to input and output.

CODE ==> KeyedAccessFile(Any) add

Rep := KeyedAccessFile(Any)

library f == open f
```

```
elt(f:%,v:Symbol) == elt(f, string v)

setelt(f:%, v:Symbol, val:Any) == setelt(f, string v, val)
```

— COQ LIB —

```
(* domain LIB *)
(*
  KeyedAccessFile(Any) add

  Rep := KeyedAccessFile(Any)

  library : FileName -> %
  library f == open f

  ?? : (% ,Symbol) -> Any
  elt(f:%,v:Symbol) == elt(f, string v)

  setelt : (% ,Symbol,Any) -> Any
  setelt(f:%, v:Symbol, val:Any) == setelt(f, string v, val)

*)

```

)abbrev domain LEXP LieExponentials
++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ Description:
++ Management of the Lie Group associated with a
++ free nilpotent Lie algebra. Every Lie bracket with
++ length greater than \axiom{Order} are assumed to be null.
++ The implementation inherits from the \spadtype{XPBWPolynomial}
++ domain constructor: Lyndon coordinates are exponential coordinates

```

++ of the second kind.

```

LieSquareMatrix(n,R) implements the Lie algebra of the n by n matrices over the commutative ring R.

The Lie bracket (commutator) of the algebra is given by

$$a*b := (a * \$\$MATRIX(n,R) b - b * \$\$MATRIX(n,R) a)$$

where $\$\$MATRIX(n,R)$ is the usual matrix multiplication.

=====
LinearOrdinaryDifferentialOperator examples
=====
```

LinearOrdinaryDifferentialOperator(A, diff) is the domain of linear ordinary differential operators with coefficients in a ring A with a given derivation.

```
=====
Differential Operators with Series Coefficients
=====
```

Problem:

Find the first few coefficients of $\exp(x)/x^i$ of Dop phi where

```
Dop := D^3 + G/x^2 * D + H/x^3 - 1
phi := sum(s[i]*exp(x)/x^i, i = 0..)
```

Solution:

Define the differential.

```
Dx: LODO(EXPR INT, f +-> D(f, x))
      Type: Void

Dx := D()
D
Type: LinearOrdinaryDifferentialOperator(Expression Integer,
theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
SPADCALL(G1404,QUOTE x,
ELT(*1;anonymousFunction;0;frame0;internal;MV,0))))
```

Now define the differential operator Dop.

```
Dop:= Dx^3 + G/x^2*Dx + H/x^3 - 1
      3
      G   - x  + H
D  + -- D + -----
      2      3
      x      x
Type: LinearOrdinaryDifferentialOperator(Expression Integer,
theMap LAMBDA-CLOSURE(NIL,NIL,NIL,G1404 envArg,
SPADCALL(G1404,QUOTE x,
ELT(*1;anonymousFunction;0;frame0;internal;MV,0))))

n == 3
      Type: Void
```

```
phi == reduce(+,[subscript(s,[i])*exp(x)/x^i for i in 0..n])
Type: Void
```

```
phi1 == Dop(phi) / exp x
Type: Void
```

```
phi2 == phi1 *x**(n+3)
Type: Void
```

```
phi3 == retract(phi2)@(POLY INT)
Type: Void
```

```
pans == phi3 ::UP(x,POLY INT)
Type: Void
```

```
pans1 == [coefficient(pans, (n+3-i) :: NNI) for i in 2..n+1]
Type: Void
```

```
leq == solve(pans1,[subscript(s,[i]) for i in 1..n])
Type: Void
```

Evaluate this for several values of n.

=====
LinearOrdinaryDifferentialOperator1 example
=====
```

LinearOrdinaryDifferentialOperator1(A) is the domain of linear ordinary differential operators with coefficients in the differential ring A.

```
=====
Differential Operators with Rational Function Coefficients
=====
```

This example shows differential operators with rational function coefficients. In this case operator multiplication is non-commutative and, since the coefficients form a field, an operator division algorithm exists.

We begin by defining RFZ to be the rational functions in x with integer coefficients and Dx to be the differential operator for d/dx.

```
RFZ := Fraction UnivariatePolynomial('x, Integer)
      Fraction UnivariatePolynomial(x,Integer)
                        Type: Domain

x : RFZ := 'x
  x
                        Type: Fraction UnivariatePolynomial(x,Integer)

Dx : LOD01 RFZ := D()
  D
                        Type: LinearOrdinaryDifferentialOperator1
                        Fraction UnivariatePolynomial(x,Integer)
```

Operators are created using the usual arithmetic operations.

```
b : LOD01 RFZ := 3*x**2*Dx**2 + 2*Dx + 1/x
      2 2      1
      3x D  + 2D + -
                        x
                        Type: LinearOrdinaryDifferentialOperator1
                        Fraction UnivariatePolynomial(x,Integer)
```

```

a : LODO1 RFZ := b*(5*x*Dx + 7)
      3 3      2      2      7
    15x D  + (51x  + 10x)D  + 29D + -
                                   x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)

```

Operator multiplication corresponds to functional composition.

```

p := x**2 + 1/x**2
      4
      x  + 1
      ----
      2
      x
Type: Fraction UnivariatePolynomial(x,Integer)

```

Since operator coefficients depend on x, the multiplication is not commutative.

```

(a*b - b*a) p
      4
    - 75x  + 540x - 75
    -----
      4
      x
Type: Fraction UnivariatePolynomial(x,Integer)

```

When the coefficients of operator polynomials come from a field, as in this case, it is possible to define operator division. Division on the left and division on the right yield different results when the multiplication is non-commutative.

The results of leftDivide and rightDivide are quotient-remainder pairs satisfying:

```

leftDivide(a,b) = [q, r] such that a = b*q + r
rightDivide(a,b) = [q, r] such that a = q*b + r

```

In both cases, the degree of the remainder, r, is less than the degree of b.

```

ld := leftDivide(a,b)
[quotient= 5x D + 7,remainder= 0]
Type: Record(quotient: LinearOrdinaryDifferentialOperator1
              Fraction UnivariatePolynomial(x,Integer),
              remainder: LinearOrdinaryDifferentialOperator1
              Fraction UnivariatePolynomial(x,Integer))

a = b * ld.quotient + ld.remainder

```

$$15x^3 D^3 + (51x^2 + 10x)D^2 + 29D + - = 15x^3 D^3 + (51x^2 + 10x)D^2 + 29D + -$$

Type: Equation LinearOrdinaryDifferentialOperator1
 Fraction UnivariatePolynomial(x,Integer)

The operations of left and right division are so-called because the quotient is obtained by dividing a on that side by b.

```
rd := rightDivide(a,b)
[quotient= 5x D + 7,remainder= 10D + -]
Type: Record(quotient: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer),
             remainder: LinearOrdinaryDifferentialOperator1
             Fraction UnivariatePolynomial(x,Integer))

a = rd.quotient * b + rd.remainder
15x^3 D^3 + (51x^2 + 10x)D^2 + 29D + - = 15x^3 D^3 + (51x^2 + 10x)D^2 + 29D + -
Type: Equation LinearOrdinaryDifferentialOperator1
Fraction UnivariatePolynomial(x,Integer)
```

Operations rightQuotient and rightRemainder are available if only one of the quotient or remainder are of interest to you. This is the quotient from right division.

```
rightQuotient(a,b)
5x D + 7
Type: LinearOrdinaryDifferentialOperator1
Fraction UnivariatePolynomial(x,Integer)
```

This is the remainder from right division. The corresponding "left" functions, leftQuotient and leftRemainder are also available.

```
rightRemainder(a,b)
5
10D + -
x
Type: LinearOrdinaryDifferentialOperator1
Fraction UnivariatePolynomial(x,Integer)
```

For exact division, operations leftExactQuotient and rightExactQuotient are supplied. These return the quotient but only if the remainder is zero. The call rightExactQuotient(a,b) would yield an error.

```
leftExactQuotient(a,b)
5x D + 7
Type: Union(LinearOrdinaryDifferentialOperator1
            Fraction UnivariatePolynomial(x,Integer),...)
```

The division operations allow the computation of left and right greatest

common divisors, leftGcd and rightGcd via remainder sequences, and consequently the computation of left and right least common multiples, rightLcm and leftLcm.

```
e := leftGcd(a,b)
      2 2      1
    3x D  + 2D + -
              x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)
```

Note that a greatest common divisor doesn't necessarily divide a and b on both sides. Here the left greatest common divisor does not divide a on the right.

```
leftRemainder(a, e)
0
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)
```

```
rightRemainder(a, e)
      5
    10D + -
          x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)
```

Similarly, a least common multiple is not necessarily divisible from both sides.

```
f := rightLcm(a,b)
      3 3      2      2      7
    15x D  + (51x  + 10x)D  + 29D + -
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)
```

```
rightRemainder(f, b)
      5
    10D + -
          x
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)
```

```
leftRemainder(f, b)
0
Type: LinearOrdinaryDifferentialOperator1
      Fraction UnivariatePolynomial(x,Integer)
```

=====
LinearOrdinaryDifferentialOperator2
=====

```

LinearOrdinaryDifferentialOperator2(A, M) is the domain of linear ordinary differential operators with coefficients in the differential ring A and operating on M, an A-module. This includes the cases of operators which are polynomials in D acting upon scalar or vector expressions of a single variable. The coefficients of the operator polynomials can be integers, rational functions, matrices or elements of other domains.

```
=====
Differential Operators with Constant Coefficients
=====
```

This example shows differential operators with rational number coefficients operating on univariate polynomials.

We begin by making type assignments so we can conveniently refer to univariate polynomials in x over the rationals.

```
Q  := Fraction Integer
    Fraction Integer
                                Type: Domain

PQ := UnivariatePolynomial('x, Q)
    UnivariatePolynomial(x,Fraction Integer)
                                Type: Domain

x: PQ := 'x
    x
                                Type: UnivariatePolynomial(x,Fraction Integer)
```

Now we assign Dx to be the differential operator D corresponding to d/dx .

```
Dx: LODO2(Q, PQ) := D()
    D
    Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
        UnivariatePolynomial(x,Fraction Integer))
```

New operators are created as polynomials in $D()$.

```
a := Dx + 1
    D + 1
    Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
        UnivariatePolynomial(x,Fraction Integer))

b := a + 1/2*Dx**2 - 1/2
    1 2      1
    - D + D + -
    2      2
    Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
        UnivariatePolynomial(x,Fraction Integer))
```

To apply the operator a to the value p the usual function call syntax is used.

```
p := 4*x**2 + 2/3
    2 2
    4x + -
```

```

3
Type: UnivariatePolynomial(x,Fraction Integer)

a p
  2      2
4x  + 8x + -
          3
Type: UnivariatePolynomial(x,Fraction Integer)

```

Operator multiplication is defined by the identity $(a*b)p = a(b(p))$

```

(a * b) p = a b p
  2      37      2      37
2x  + 12x + --- 2x  + 12x + ---
          3          3
Type: Equation UnivariatePolynomial(x,Fraction Integer)

```

Exponentiation follows from multiplication.

```

c := (1/9)*b*(a + b)^2
  1 6    5 5    13 4    19 3    79 2    7    1
-- D + -- D + -- D + -- D + -- D + -- D + -
  72   36    24    18    72    12    8
Type: LinearOrdinaryDifferentialOperator2(Fraction Integer,
UnivariatePolynomial(x,Fraction Integer))

```

Finally, note that operator expressions may be applied directly.

```

(a**2 - 3/4*b + c) (p + 1)
  2    44    541
3x  + -- x + ---
  3      36
Type: UnivariatePolynomial(x,Fraction Integer)

```

```

=====
Differential Operators with Matrix Coefficients Operating on Vectors}
=====

```

This is another example of linear ordinary differential operators with non-commutative multiplication. Unlike the rational function case, the differential ring of square matrices (of a given dimension) with univariate polynomial entries does not form a field. Thus the number of operations available is more limited.

In this section, the operators have three by three matrix coefficients with polynomial entries.

```

PZ := UnivariatePolynomial(x,Integer)
UnivariatePolynomial(x,Integer)
Type: Domain

```

```

x:PZ := 'x
      x
                                     Type: UnivariatePolynomial(x,Integer)

Mat  := SquareMatrix(3,PZ)
      SquareMatrix(3,UnivariatePolynomial(x,Integer))
                                     Type: Domain

```

The operators act on the vectors considered as a Mat-module.

```

Vect := DPMM(3, PZ, Mat, PZ)
DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer))
                                     Type: Domain

Modo := LODO2(Mat, Vect)
LinearOrdinaryDifferentialOperator2(SquareMatrix(3,UnivariatePolynomial(x,Integer)),DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),SquareMatrix(3,UnivariatePolynomial(x,Integer)),UnivariatePolynomial(x,Integer)))
                                     Type: Domain

```

The matrix m is used as a coefficient and the vectors p and q are operated upon.

```

m:Mat := matrix [ [x^2,1,0],[1,x^4,0],[0,0,4*x^2] ]
      + 2      +
      |x  1   0 |
      |      4   |
      |1  x   0 |
      |      2   |
      +0  0   4x +
                                     Type: SquareMatrix(3,UnivariatePolynomial(x,Integer))

p:Vect := directProduct [3*x^2+1,2*x,7*x^3+2*x]
      2      3
      [3x  + 1,2x,7x  + 2x]
      Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer))

q: Vect := m * p
      4      2      5      2      5      3
      [3x  + x  + 2x,2x  + 3x  + 1,28x  + 8x ]
      Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
      SquareMatrix(3,UnivariatePolynomial(x,Integer)),
      UnivariatePolynomial(x,Integer))

```

Now form a few operators.

```

Dx : Modo := D()
D
Type: LinearOrdinaryDifferentialOperator2(
  SquareMatrix(3,UnivariatePolynomial(x,Integer)),
  DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
  SquareMatrix(3,UnivariatePolynomial(x,Integer)),
  UnivariatePolynomial(x,Integer)))

a : Modo := Dx + m
      + 2      +
      |x  1    0 |
      |        |
D + |      4    |
      |1  x    0 |
      |        |
      |        2|
      +0  0  4x +
Type: LinearOrdinaryDifferentialOperator2(
  SquareMatrix(3,UnivariatePolynomial(x,Integer)),
  DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
  SquareMatrix(3,UnivariatePolynomial(x,Integer)),
  UnivariatePolynomial(x,Integer)))

b : Modo := m*Dx + 1
      + 2      +
      |x  1    0 |      +1  0  0+
      |        |      |    |
      |      4    |D + |0  1  0|
      |1  x    0 |      |    |
      |        |      +0  0  1+
      |        2|
      +0  0  4x +
Type: LinearOrdinaryDifferentialOperator2(
  SquareMatrix(3,UnivariatePolynomial(x,Integer)),
  DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
  SquareMatrix(3,UnivariatePolynomial(x,Integer)),
  UnivariatePolynomial(x,Integer)))

c := a*b
+ 2      +      + 4      4      2      +      + 2      +
|x  1    0 |      |x  + 2x + 2  x  + x      0      |      |x  1    0 | | |
|        |  2 |      |        |      |      |      |
|      4    |D + |      4      2      8      3      |D + |      4    |
|1  x    0 |      |x  + x      x  + 4x  + 2      0      |      |1  x    0 |
|        |      |      |      |
|        2|      |      |      4      |      |      2|
+0  0  4x +      +      0      0      16x  + 8x + 1+      +0  0  4x +
Type: LinearOrdinaryDifferentialOperator2(

```

```

SquareMatrix(3,UnivariatePolynomial(x,Integer)),
DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer)))

```

These operators can be applied to vector values.

```

a p
      4      2      5      2      5      3      2
[3x  + x  + 8x, 2x  + 3x  + 3, 28x  + 8x  + 21x  + 2]
Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer))

```

```

b p
      3      2      4      4      3      2
[6x  + 3x  + 3, 2x  + 8x, 84x  + 7x  + 8x  + 2x]
Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer))

```

```

(a + b + c) (p + q)
      8      7      6      5      4      3      2
[10x  + 12x  + 16x  + 30x  + 85x  + 94x  + 40x  + 40x  + 17,
      12      9      8      7      6      5      4      3      2
10x  + 10x  + 12x  + 92x  + 6x  + 32x  + 72x  + 28x  + 49x  + 32x  + 19,
      8      7      6      5      4      3      2
2240x  + 224x  + 1280x  + 3508x  + 492x  + 751x  + 98x  + 18x  + 4]
Type: DirectProductMatrixModule(3,UnivariatePolynomial(x,Integer),
SquareMatrix(3,UnivariatePolynomial(x,Integer)),
UnivariatePolynomial(x,Integer))

```

=====
List examples
=====
```

A list is a finite collection of elements in a specified order that can contain duplicates. A list is a convenient structure to work with because it is easy to add or remove elements and the length need not be constant. There are many different kinds of lists in Axiom, but the default types (and those used most often) are created by the List constructor. For example, there are objects of type List Integer, List Float and List Polynomial Fraction Integer. Indeed, you can even have List List List Boolean (that is, lists of lists of lists of Boolean values). You can have lists of any type of Axiom object.

```
=====
Creating Lists
=====
```

The easiest way to create a list with, for example, the elements 2, 4, 5, 6 is to enclose the elements with square brackets and separate the elements with commas.

The spaces after the commas are optional, but they do improve the readability.

```
[2, 4, 5, 6]
[2,4,5,6]
```

Type: List PositiveInteger

To create a list with the single element 1, you can use either [1] or the operation list.

```
[1]
[1]
```

Type: List PositiveInteger

```
list(1)
[1]
```

Type: List PositiveInteger

Once created, two lists *k* and *m* can be concatenated by issuing `append(k,m)`. `append` does not physically join the lists, but rather produces a new list with the elements coming from the two arguments.

```
append([1,2,3],[5,6,7])
[1,2,3,5,6,7]
```

Type: List PositiveInteger

Use `cons` to append an element onto the front of a list.

```
cons(10,[9,8,7])
[10,9,8,7]
```

Type: List PositiveInteger

=====

Accessing List Elements

=====

To determine whether a list has any elements, use the operation `empty?`.

```
empty? [x+1]
false
```

Type: Boolean

Alternatively, equality with the list constant `nil` can be tested.

```
([] = nil)@Boolean
true
```

Type: Boolean

We'll use this in some of the following examples.

```
k := [4,3,7,3,8,5,9,2]
[4,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

Each of the next four expressions extracts the first element of *k*.

```
first k
4
```

Type: PositiveInteger

```
k.first
4
```

Type: PositiveInteger

```
k.1
4
```

Type: PositiveInteger

```
k(1)
4
```

Type: PositiveInteger

The last two forms generalize to $k.i$ and $k(i)$, respectively, where $1 \leq i \leq n$ and n equals the length of k .

This length is calculated by $\#$.

```
n := #k
8
```

Type: PositiveInteger

Performing an operation such as $k.i$ is sometimes referred to as indexing into k or elting into k . The latter phrase comes about because the name of the operation that extracts elements is called `elt`. That is, $k.3$ is just alternative syntax for `elt(k,3)`. It is important to remember that list indices begin with 1. If we issue $k := [1,3,2,9,5]$ then $k.4$ returns 9. It is an error to use an index that is not in the range from 1 to the length of the list.

The last element of a list is extracted by any of the following three expressions.

```
last k
2
```

Type: PositiveInteger

```
k.last
2
```

Type: PositiveInteger

This form computes the index of the last element and then extracts the element from the list.

```
k.(#k)
2
```

Type: PositiveInteger

=====

Changing List Elements

=====

We'll use this in some of the following examples.

```
k := [4,3,7,3,8,5,9,2]
[4,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

List elements are reset by using the `k.i` form on the left-hand side of an assignment. This expression resets the first element of `k` to 999.

```
k.1 := 999
999
```

Type: PositiveInteger

As with indexing into a list, it is an error to use an index that is not within the proper bounds. Here you see that `k` was modified.

```
k
[999,3,7,3,8,5,9,2]
```

Type: List PositiveInteger

The operation that performs the assignment of an element to a particular position in a list is called `setelt`. This operation is destructive in that it changes the list. In the above example, the assignment returned the value 999 and `k` was modified. For this reason, lists are called mutable objects: it is possible to change part of a list (mutate it) rather than always returning a new list reflecting the intended modifications.

Moreover, since lists can share structure, changes to one list can sometimes affect others.

```
k := [1,2]
[1,2]
```

Type: List PositiveInteger

```
m := cons(0,k)
[0,1,2]
```

Type: List Integer

Change the second element of `m`.

```
m.2 := 99
99
```

Type: PositiveInteger

See, `m` was altered.

```
m
[0,99,2]
```

Type: List Integer

But what about `k`? It changed too!

```
k
[99,2]
```

Type: List PositiveInteger

Dot, Dot

=====

Certain lists are used so often that Axiom provides an easy way of constructing them. If n and m are integers, then `expand [n..m]` creates a list containing $n, n+1, \dots m$. If $n > m$ then the list is empty. It is actually permissible to leave off the m in the dot-dot construction (see below).

The dot-dot notation can be used more than once in a list construction and with specific elements being given. Items separated by dots are called segments.

```
[1..3,10,20..23]
[1..3,10..10,20..23]
```

Type: List Segment PositiveInteger

Segments can be expanded into the range of items between the endpoints by using `expand`.

```
expand [1..3,10,20..23]
[1,2,3,10,20,21,22,23]
```

Type: List Integer

What happens if we leave off a number on the right-hand side of `..`?

```
expand [1..]
[1,2,3,4,5,6,7,8,9,10,...]
```

Type: Stream Integer

What is created in this case is a Stream which is a generalization of a list.

)abbrev domain LMOPS ListMonoidOps
++ Author: Manuel Bronstein
++ Date Created: November 1989
++ Date Last Updated: 6 June 1991
++ Description:
++ This internal package represents monoid (abelian or not, with or
++ without inverses) as lists and provides some common operations
++ to the various flavors of monoids.

ListMonoidOps(S, E, un) : SIG == CODE where
  S : SetCategory
  E : AbelianMonoid
  un : E

REC ==> Record(gen:S, exp: E)
0 ==> OutputForm

SIG ==> Join(SetCategory, RetractableTo S) with

outputForm : ($, (0, 0) -> 0, (0, 0) -> 0, Integer) -> 0
++ outputForm(l, fop, fexp, unit) converts the monoid element
++ represented by l to an \spadtype{OutputForm}.
++ Argument unit is the output form
++ for the \spadignore{unit} of the monoid (for example. 0 or 1),
++ \spad{fop(a, b)} is the
++ output form for the monoid operation applied to \spad{a} and b
++ (for example \spad{a + b}, \spad{a * b}, \spad{ab}),
++ and \spad{fexp(a, n)} is the output form
++ for the exponentiation operation applied to \spad{a} and n
++ (for example \spad{n a}, \spad{n * a}, \spad{a ** n}, \spad{a\^n}).

listOfMonoms : $ -> List REC
++ listOfMonoms(l) returns the list of the monomials forming l.

makeTerm : (S, E) -> $
++ makeTerm(s, e) returns the monomial s exponentiated by e
++ (for example, s^e or e * s).

makeMulti : List REC -> $
++ makeMulti(l) returns the element whose list of monomials is l.

```

```

nthExpon : ($, Integer) -> E
  ++ nthExpon(l, n) returns the exponent of the nth monomial of l.

nthFactor : ($, Integer) -> S
  ++ nthFactor(l, n) returns the factor of the nth monomial of l.

reverse : $ -> $
  ++ reverse(l) reverses the list of monomials forming l. This
  ++ has some effect if the monoid is non-abelian,
  ++ \spad{reverse(a1\^e1 ... an\^en) = an\^en ... a1\^e1} which is
  ++ different.

reverse_! : $ -> $
  ++ reverse!(l) reverses the list of monomials forming l, destroying
  ++ the element l.

size : $ -> NonNegativeInteger
  ++ size(l) returns the number of monomials forming l.

makeUnit : () -> $
  ++ makeUnit() returns the unit element of the monomial.

rightMult : ($, S) -> $
  ++ rightMult(a, s) returns \spad{a * s} where \spad{*}
  ++ is the monoid operation,
  ++ which is assumed non-commutative.

leftMult : (S, $) -> $
  ++ leftMult(s, a) returns \spad{s * a} where
  ++ \spad{*} is the monoid operation,
  ++ which is assumed non-commutative.

plus : (S, E, $) -> $
  ++ plus(s, e, x) returns \spad{e * s + x} where \spad{+}
  ++ is the monoid operation,
  ++ which is assumed commutative.

plus : ($, $) -> $
  ++ plus(x, y) returns \spad{x + y} where \spad{+}
  ++ is the monoid operation,
  ++ which is assumed commutative.

commutativeEquality : ($, $) -> Boolean
  ++ commutativeEquality(x,y) returns true if x and y are equal
  ++ assuming commutativity

mapExpon : (E -> E, $) -> $
  ++ mapExpon(f, a1\^e1 ... an\^en) returns \spad{a1\^f(e1) ... an\^f(en)}.

mapGen : (S -> S, $) -> $

```

```

++ mapGen(f, a1\^e1 ... an\^en) returns \spad{f(a1)\^e1 ... f(an)\^en}.

=====
LyndonWord examples
=====
```

A function f in $[0,1]$ is called acyclic if $C(F)$ consists of n different objects. The canonical representative of the orbit of an acyclic function is usually called a Lyndon Word. If f is acyclic, then all elements in the orbit $C(f)$ are acyclic as well, and we call $C(f)$ an acyclic orbit.

)abbrev domain LWORD LyndonWord
++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ References:
++ Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ Description:
++ Lyndon words over arbitrary (ordered) symbols:
++ see Free Lie Algebras by C. Reutenauer (Oxford science publications).
++ A Lyndon word is a word which is smaller than any of its right factors
++ w.r.t. the pure lexicographical ordering.
++ If \axiom{a} and \axiom{b} are two Lyndon words such that \axiom{a < b}
++ holds w.r.t lexicographical ordering then \axiom{a*b} is a Lyndon word.
++ Parenthesized Lyndon words can be generated from symbols by using the
++ following rule:\br
++ \axiom{[[a,b],c]} is a Lyndon word iff \axiom{a*b < c <= b} holds.\br
++ Lyndon words are internally represented by binary trees using the
++ \spadtype{Magma} domain constructor.
++ Two ordering are provided: lexicographic and
++ length-lexicographic.

++ Author: Michel Petitot (petitot@lifl.fr).
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Fix History: compilation v 2.1 le 13 dec 98
++ Description:
++ This type is the basic representation of
++ parenthesized words (binary trees over arbitrary symbols)
++ useful in \spadtype{LiePolynomial}.

Magma(VarSet) : SIG == CODE where
  VarSet : OrderedSet

  WORD ==> OrderedFreeMonoid(VarSet)
  EX   ==> OutputForm

  SIG ==> Join(OrderedSet,RetractableTo VarSet) with

    "*" : ($,$) -> $
    ++ \axiom{x*y} returns the tree \axiom{[x,y]}.

  coerce : $ -> WORD
    ++ \axiom{coerce(x)} returns the element of
    ++ \axiomType{OrderedFreeMonoid}(VarSet)
    ++ corresponding to \axiom{x} by removing parentheses.

```

```

first : $ -> VarSet
  ++ \axiom{first(x)} returns the first entry of the tree \axiom{x}.

left : $ -> $
  ++ \axiom{left(x)} returns left subtree of \axiom{x} or
  ++ error if retractable?(x) is true.

length : $ -> PositiveInteger
  ++ \axiom{length(x)} returns the number of entries in \axiom{x}.

lexico : ($,$) -> Boolean
  ++ \axiom{lexico(x,y)} returns \axiom{true} iff \axiom{x} is smaller
  ++ than \axiom{y} w.r.t. the lexicographical ordering induced by
  ++ \axiom{VarSet}.
  ++ N.B. This operation does not take into account the tree structure of
  ++ its arguments. Thus this is not a total ordering.

mirror : $ -> $
  ++ \axiom{mirror(x)} returns the reversed word of \axiom{x}.
  ++ That is \axiom{x} itself if retractable?(x) is true and
  ++ \axiom{mirror(z) * mirror(y)} if \axiom{x} is \axiom{y*z}.

rest : $ -> $
  ++ \axiom{rest(x)} return \axiom{x} without the first entry or
  ++ error if retractable?(x) is true.

retractable? : $ -> Boolean
  ++ \axiom{retractable?(x)} tests if \axiom{x} is a tree with
  ++ only one entry.

right : $ -> $
  ++ \axiom{right(x)} returns right subtree of \axiom{x} or
  ++ error if retractable?(x) is true.

varList : $ -> List VarSet
  ++ \axiom{varList(x)} returns the list of distinct entries of \axiom{x}

MathMLFormat examples

=====

This package is based on the TeXFormat domain by Robert S. Sutor
 MathMLFormat provides a coercion from OutputForm to MathML format.

See Also:

o)show MathMLFormat

Both this code and documentation are still under development and I don't pretend they are anywhere close to perfect or even finished. However the code does work and I hope it might be useful to somebody both for it's ability to output MathML from Axiom and as an example of how to write a new output form.

Introduction to Mathematical Markup Language

MathML exists in two forms: presentation and content. At this time (2007-02-11) the package only has a presentation package. A content package is in the works however it is more difficult. Unfortunately Axiom does not make its semantics easily available. The `OutputForm` domain mediates between the individual Axiom domains and the user visible output but `OutputForm` does not provide full semantic information. From my currently

incomplete understanding of Axiom it appears that remedying this would entail going back to the individual domains and rewriting a lot of code. However some semantics are conveyed directly by `OutputForm` and other things can be deduced from `OutputForm` or from the original user command.

Displaying MathML

The MathML string produced by `)set output mathml on` can be pasted directly into an appropriate xhtml page and then viewed in Firefox or some other MathML aware browser. The boiler plate code needed for a test page, `testmathml.xml`, is:

```
<?xml version="1.0" ?>

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 plus MathML 2.0//EN"
    "http://www.w3.org/Math/DTD/mathml2/xhtml-math11-f.dtd" [
<!ENTITY mathml "http://www.w3.org/1998/Math/MathML">
]>

<html xmlns="http://www.w3.org/1999/xhtml"
      xmlns:xlink="http://www.w3.org/1999/xlink" >

  <head>
    <title>MathML Test </title>
  </head>

  <body>

    </body>
</html>
```

Paste the MathML string into the body element and it should display nicely in Firefox.

Test Cases

Here's a list of test cases that currently format correctly:

1. $(x+y)^{**2}$
2. $\text{integrate}(x^{**x}, x)$
3. $\text{integral}(x^{**x}, x)$
4. $(5 + \sqrt{63} + \sqrt{847})^{**(1/3)}$
5. $\text{set } [1, 2, 3]$
6. $\text{multiset } [x \bmod 5 \text{ for } x \text{ in primes}(2, 1000)]$
7. $\text{series}(\sin(ax), x=0)$

8. `matrix [ [x**i + y**j for i in 1..10] for j in 1..10]`
9. `y := operator 'y a. D(y(x,z),[x,x,z,x]) b. D(y x,x,2)`
10. `x := series 'x a. sin(1+x)`
11. `series(1/log(y),y=1)`
12. `y:UTS(FLOAT,'z,0) := exp(z)`
13. a. `c := continuedFraction(314159/100000)` b. `c := continuedFraction(314159/100000)`

The `TexFormat` domain has the capability to format an object with subscripts, superscripts, presubscripts and presuperscripts however I don't know of any Axiom command that produces such an object. In fact at present I see the case of "SUPERSUB" being used for putting primes in the superscript position to denote ordinary differentiation. I also only see the "SUB" case being used to denote partial derivatives.

)set output mathml on

Making `mathml` appear as output during a normal Axiom session by invoking `)set output mathml on` proved to be a bit tedious and seems to be undocumented. I document my experience here in case it proves useful to somebody else trying to get a new output format from Axiom.

In `MathMLFormat` the functions `coerce(expr : OutputForm) : String` and `display(s : String) : Void` provide the desired `mathml` output. Note that this package was constructed by close examination of Robert Sutor's `TexFormat` domain and much remains from that source. To have `mathml` displayed as output we need to get Axiom to call `display(coerce(expr))` at the appropriate place. Here's what I did to get that to happen. Note that my starting point here was an attempt by Andrey Grozin to do the same. To figure things out I searched through files for "tex" to see what was done for the `TexFormat` domain, and used `grep` to find which files had mention of `TexFormat`.

File src/interp/setvars.boot.pamphlet

Create an output `mathml` section by analogy to the `tex` section. Remember to add the code chunk `"outputmathmlCode"` at the end.

`setvars.boot` is a bootstrap file which means that it has to be precompiled into lisp code and then that code has to be inserted back into `setvars.boot`. To do this extract the boot code by running `"notangle"` on it. I did this from the `"tmp"` directory. From inside axiom run `)lisp (boottran::boottocl "tmp/setvars.boot")` which put `"setvars.clisp"` into `"int/interp/setvars.clisp"`. Then replace the lisp in `"setvars.boot.pamphlet"` with that in the newly generated `"setvars.clisp"`.

The relevant code chunks appearing in `"setvars.boot.pamphlet"` are:

```
outputmathmlCode
setOutputMathml
describeSetOutputMathml
```

and the relevant variables are:

```
setOutputMathml
$mathmlOutputStream
$mathmlOutputFile
$mathmlFormat
describeSetOutputMathml
```

File setvar.boot.pamphlet

Create an output mathml section in "setvar.boot.pamphlet" again patterned after the tex section. I changed the default file extension from ".stex" to ".smml".

To the "sectionoutput" table I added the line

```
mathml          created output in MathML style      Off:CONSOLE
```

Added the code chunk "outputmathml" to the code chunk "output" in "sectionoutput".

Relevant code chunks:

```
outputmathml
```

Relevant variables:

```
setOutputMathml
$mathmlFormat
$mathmlOutputFile
```

Note when copying the tex stuff I changed occurrences of "tex" to "mathml", "Tex" to "Mathml" and "TeX" to "MathML".

File src/algebra/Makefile.pamphlet

The file "src/algebra/tex.spad.pamphlet" contains the domain `TexFormat` (TEX) and the package `TexFormat1` (TEX1). However the sole function of `TexFormat1` is to **coerce** objects from a domain into `OutputForm` and then apply `TexFormat` to them. It is to save programmers the trouble of doing the coercion themselves from inside spad code. It does not appear to be used for the main purpose of delivering Axiom output in TeX format. In order to keep the mathml package as simple as possible, and because I didn't see much use for this, I didn't copy the `TexFormat1` package. So no analog of the TEX1 entries in "Makefile.pamphlet" were needed. One curiosity I don't understand is why TEX1 appears in layer 4 when it seems to depend on TEX which appears in layer 14.

Initially I added "\$OUT/MMLFORM.o" to layer 14 and "mathml.spad.pamphlet" to completed spad files in layer 14. When trying to compile the build failed at MMLFORM. It left "MMLFORM.erlib" in "int/algebra" instead of "MMLFORM.NRLIB" which confused me at first because mathml.spad compiled under a running axiom. By examining the file

"obj/tmp/trace" I saw that a new dependency had been introduced, compared to `TeXFormat`, with the function `eltName` depending on the domain `FSAGG` in layer 16. So the lines had to be moved from layer 14 to layer 17.

Added appropriate lines to "SPADFILES" and "DOCFILES".

File `src/algebra/exposed.lsp.pamphlet`

Add the line "(`|MathMLFormat|` . `MMLFORM`)"

File `src/algebra/Lattice.pamphlet`

I don't see that this file is used anywhere but I made the appropriate changes anyway by searching for "TEX" and mimicing everything for `MMLFORM`.

File `src/doc/axiom.bib.pamphlet`

Added `mathml.spad` subsection to "src/doc/axiom.bib.pamphlet".

File `interp/i-output.boot.pamphlet`

This is where the `coerce` and `display` functions from `MathMLFormat` actually get called. The following was added:

```
mathmlFormat expr ==
  mml := '(MathMLFormat)
  mmlrep := '(String)
  formatFn := getFunctionFromDomain("coerce",mml,[$OutputForm])
  displayFn := getFunctionFromDomain("display",mml,[mmlrep])
  SPADCALL(SPADCALL(expr,formatFn),displayFn)
  TERPRI $mathmlOutputStream
  FORCE_-OUTPUT $mathmlOutputStream
  NIL
```

Note that compared to the `texFormat` function there are a couple of differences. Since `MathMLFormat` is currently a package rather than a domain there is the "mmlrep" variable whereas in `texFormat` the argument of the "display" function is an instance of the domain. Also the `coerce` function here only has one argument, namely "\$OutputForm".

Also for the function "output(expr,domain)" add lines for `mathml`, for example, "if \$mathml-Format then mathmlFormat expr".

After these changes Axiom compiled with `mathml` enabled under `)set output`.

Public Declarations

The declarations

```
E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)
```

provide abbreviations for domains used heavily in the code. The publicly exposed functions are:

coerce: E -> S This function is the main one for converting an expression in domain `OutputForm` into a MathML string.

coerceS: E -> S This function is for use from the command line. It converts an `OutputForm` expression into a MathML string and does some formatting so that the output is not one long line. If you take the output from this function, stick it in an emacs buffer in `nxml-mode` and then indent according to mode, you'll get something that's nicer to look at than what comes from `coerce`. Note that `coerceS` returns the same value as `coerce` but invokes a display function as well so that the result will be printed twice in different formats. The need for this is that the output from `coerce` is automatically formatted with line breaks by Axiom's output routine that are not in the right place.

coerceL: E -> S Similar to `coerceS` except that the displayed result is the MathML string in one long line. These functions can be used, for instance, to get the MathML for the previous result by typing `coerceL(`

expres: E -> S Converts `OutputForm` to `String` with the structure preserved with braces. This is useful in developing this package. Actually this is not quite accurate. The function **precondition** is first applied to the `OutputForm` expression before **expres**. Raw `OutputForm` and the nature of the **precondition** function is still obscure to me at the time of this writing (2007-02-14), however I probably need to understand it to make sure I'm not missing any semantics. The `spad` function **precondition** is just a wrapper for the lisp function `outputTran$Lisp`, which I guess is compiled from `boot`.

display: S -> Void This one prints the string returned by `coerce` as one long line, adding "math" tags: `<math ...> ... </math>`. Thus the output from this can be stuck directly into an appropriate `html/xhtml` page and will be displayed nicely by a MathML aware browser.

displayF: S -> Void This function doesn't exist yet but it would be nice to have a humanly readable formatted output as well. The basics do exist in the `coerceS` function however the formatting still needs some work to be really good.

Private Function Declarations

These are the local functions:

addBraces:S -> S

addBrackets:S -> S

atomize:E -> L E

displayElt:S -> Void function for recursively displaying mathml nicely formatted

eltLimit:(S,I,S) -> I demarcates end postion of mathml element with name:S starting at position i:I in mathml string s:S and returns end of end tag as i:I position in mathml string, find start and end of substring: <name ...>...</name>

eltName:(I,S) -> S find name of mathml element starting at position i:I in string s:S

group:S -> S

formatBinary:(S,L E, I) -> S

formatFunction:(S,L E, I) -> S

formatMatrix:L E -> S

formatNary:(S,L E, I) -> S

formatNaryNoGroup:(S,L E, I) -> S

formatNullary:S -> S

formatPlex:(S,L E, I) -> S

formatSpecial:(S,L E, I) -> S

formatUnary:(S, E, I) -> S

formatMml:(E,I) -> S

newWithNum:I -> \$ this is a relic from tex.spad and is not used here so far. I'll probably remove it.

parenthesize:S -> S

precondition:E -> E this function is applied to the OutputForm expression before doing anything else.

postcondition:S -> S this function is applied after all other OutputForm -> MathML transformations. In the TexFormat domain the ungroup function first peels off the outermost set of braces however I have replaced braces with <mrow>s here and sometimes the outermost set of <mrow>s is necessary to get proper display in Firefox. For instance with getting the correct size of brackets on a matrix the whole expression needs to be enclosed in a mrow element. It also checks for +- and removes the +.

stringify:E -> S

tagEnd:(S,I,S) -> I finds closing ">" of start or end tag for mathML element for formatting MathML string for human readability. No analog in TexFormat.

ungroup:S -> S

Public Function Definitions

Note that I use the function `sayTeX$Lisp` much as I would `printf` in a C program. I've noticed in grepping the code that there are other "say" functions, `sayBrightly` and `sayMessage` for instance, but I have no idea what the difference is between them at this point. `sayTeX$Lisp` does the job so for the time being I'll use that until I learn more.

The functions `coerceS` and `coerceL` should probably be changed to display functions, `displayS` and `displayL`, returning `Void`. I really only need the one `coerce` function.

— public function definitions —

```
-- public function definitions

Formatting Functions

Still need to format `\zag` in `formatSpecial`!

In `formatPlex` the case `op = "INTSIGN"` is now passed off to `formatIntSign` which is a change from the `TexFormat` domain. This is done here for presentation mark up to replace the ugly bound variable that Axiom delivers. For content mark up this has to be done anyway.

The `formatPlex` function also allows for `op = "INDEFINTEGRAL"`. However I don't know what Axiom command gives rise to this case. The `INTSIGN` case already allows for both definite and indefinite integrals.

In the function `formatSpecial` various cases are handled including `SUB` and `SUPERSUB`. These cases are now caught in `formatMml` and so the code in `formatSpecial` doesn't get executed. The only cases I know of using these are partial derivatives for `SUB` and ordinary derivatives or `SUPERSUB` however in `TexFormat` the capability is there to handle multi-scripts, an object with subscripts, superscripts, pre-subscripts and pre-superscripts but I am so far unaware of any Axiom command that produces such a multiscripted object.

Another question is how to represent derivatives. At present I have differential notation for partials and prime notation for ordinary derivatives, but it would be nice to allow for different derivative notations in different circumstances, maybe some options to `)set output mathml on`.

Ordinary derivatives are formatted in `formatSuperSub` and there are 2 versions, `formatSuperSub` and `formatSuperSub1`, which at this point have to be switched by swapping names.

=====
MathMLFormat examples
=====

```

MathML is an HTML-like markup language for mathematics. It uses the "knuckle" syntax of HTML such as "<mo>" to introduce a math operator and "</mo>" to mark the end of the operator. Axiom can generate MathML output and does so when it communicates to the browser front end.

This output is enabled by

```
)set output mathml on
```

after which you'll see the MathML markup as well as the algebra. Note that you can turn off the algebra output with

```
)set output algebra off
```

but we don't do that here so you can compare the output.

— Matrix.help —

=====

Matrix examples

=====

The Matrix domain provides arithmetic operations on matrices and standard functions from linear algebra. This domain is similar to the TwoDimensionalArray domain, except that the entries for Matrix must belong to a Ring.

=====

Creating Matrices

=====

There are many ways to create a matrix from a collection of values or from existing matrices.

If the matrix has almost all items equal to the same value, use `new` to create a matrix filled with that value and then reset the entries that are different.

```
m : Matrix(Integer) := new(3,3,0)
+0  0  0+
|      |
|0  0  0|
|      |
+0  0  0+
Type: Matrix Integer
```

To change the entry in the second row, third column to 5, use `setelt`.

```
setelt(m,2,3,5)
5
Type: PositiveInteger
```

An alternative syntax is to use assignment.

```
m(1,2) := 10
10
Type: PositiveInteger
```

The matrix was destructively modified.

```
m
+0  10  0+
|      |
|0  0  5|
|      |
+0  0  0+
Type: Matrix Integer
```

If you already have the matrix entries as a list of lists, use `matrix`.

```
matrix [ [1,2,3,4],[0,9,8,7] ]
+1  2  3  4+
|      |
+0  9  8  7+
Type: Matrix Integer
```

If the matrix is diagonal, use `diagonalMatrix`.

```
dm := diagonalMatrix [1,x**2,x**3,x**4,x**5]
+1  0  0  0  0 +
|      |
|      2      |
|0  x  0  0  0 |
|      |
```

```

|      3      |
|0  0  x  0  0|
|      |
|      4      |
|0  0  0  x  0|
|      |
|      5      |
+0  0  0  0  x +

```

Type: Matrix Polynomial Integer

Use `setRow` and `setColumn` to change a row or column of a matrix.

```
setRow!(dm,5,vector [1,1,1,1,1])
```

```

+1  0  0  0  0+
|
|      2      |
|0  x  0  0  0|
|      |
|      3      |
|0  0  x  0  0|
|      |
|      4      |
|0  0  0  x  0|
|      |
+1  1  1  1  1+

```

Type: Matrix Polynomial Integer

```
setColumn!(dm,2,vector [y,y,y,y,y])
```

```

+1  y  0  0  0+
|
|0  y  0  0  0|
|      |
|      3      |
|0  y  x  0  0|
|      |
|      4      |
|0  y  0  x  0|
|      |
+1  y  1  1  1+

```

Type: Matrix Polynomial Integer

Use `copy` to make a copy of a matrix.

```
cdm := copy(dm)
```

```

+1  y  0  0  0+
|
|0  y  0  0  0|
|      |
|      3      |
|0  y  x  0  0|

```

```

|
|      4
|0 y 0 x 0|
|
+1 y 1 1 1+
Type: Matrix Polynomial Integer

```

This is useful if you intend to modify a matrix destructively but want a copy of the original.

```

setelt(dm,4,1,1-x**7)
7
- x  + 1
Type: Polynomial Integer

[dm,cdm]
+ 1 y 0 0 0+ +1 y 0 0 0+
| | | |
| 0 y 0 0 0| |0 y 0 0 0|
| | | |
| 3 | | 3 |
| | | |
| 0 y x 0 0| |0 y x 0 0|
| | | |
| 7 4 | | 4 |
|- x + 1 y 0 x 0| |0 y 0 x 0|
| | | |
+ 1 y 1 1 1+ +1 y 1 1 1+
Type: List Matrix Polynomial Integer

```

Use `subMatrix` to extract part of an existing matrix. The syntax is `subMatrix(m, firstrow, lastrow, firstcol, lastcol)`.

```

subMatrix(dm,2,3,2,4)
+y 0 0+
| |
| 3 |
+y x 0+
Type: Matrix Polynomial Integer

```

To change a submatrix, use `setsubMatrix`.

```

d := diagonalMatrix [1.2,-1.3,1.4,-1.5]
+1.2 0.0 0.0 0.0 +
|
|0.0 - 1.3 0.0 0.0|
|
|0.0 0.0 1.4 0.0|
|
+0.0 0.0 0.0 - 1.5+
Type: Matrix Float

```

If e is too big to fit where you specify, an error message is displayed. Use `subMatrix` to extract part of e , if necessary.

```
e := matrix [ [6.7,9.11],[-31.33,67.19] ]
      + 6.7    9.11 +
      |          |
      +- 31.33 67.19+
                        Type: Matrix Float
```

This changes the submatrix of d whose upper left corner is at the first row and second column and whose size is that of e .

```
setsubMatrix!(d,1,2,e)
      +1.2    6.7    9.11    0.0 +
      |          |          |
      |0.0 - 31.33 67.19  0.0 |
      |          |          |
      |0.0    0.0    1.4    0.0 |
      |          |          |
      +0.0    0.0    0.0 - 1.5+
                        Type: Matrix Float
```

```
d
      +1.2    6.7    9.11    0.0 +
      |          |          |
      |0.0 - 31.33 67.19  0.0 |
      |          |          |
      |0.0    0.0    1.4    0.0 |
      |          |          |
      +0.0    0.0    0.0 - 1.5+
                        Type: Matrix Float
```

Matrices can be joined either horizontally or vertically to make new matrices.

```
a := matrix [ [1/2,1/3,1/4],[1/5,1/6,1/7] ]
      +1  1  1+
      |- - -|
      |2  3  4|
      |    |
      |1  1  1|
      |- - -|
      +5  6  7+
                        Type: Matrix Fraction Integer
```

```
b := matrix [ [3/5,3/7,3/11],[3/13,3/17,3/19] ]
      +3  3  3+
      |- - --|
      |5  7  11|
```

```

|      |
| 3   3   3|
|--  --  --|
+13  17  19+

```

Type: Matrix Fraction Integer

Use `horizConcat` to append them side to side. The two matrices must have the same number of rows.

```

horizConcat(a,b)
+1  1  1  3   3   3+
|-  -  -  -   -  --|
|2  3  4  5   7  11|
|      |
|1  1  1  3   3   3|
|-  -  -  --  --  --|
+5  6  7  13  17  19+

```

Type: Matrix Fraction Integer

Use `vertConcat` to stack one upon the other. The two matrices must have the same number of columns.

```

vab := vertConcat(a,b)
+1  1  1  +
|-  -  -  |
|2  3  4  |
|      |
|1  1  1  |
|-  -  -  |
|5  6  7  |
|      |
|3  3  3  |
|-  -  --|
|5  7  11|
|      |
| 3  3  3|
|--  --  --|
+13  17  19+

```

Type: Matrix Fraction Integer

The operation `transpose` is used to create a new matrix by reflection across the main diagonal.

```

transpose vab
+1  1  3   3+
|-  -  -  --|
|2  5  5  13|
|      |
|1  1  3   3|
|-  -  -  --|

```

```

|3  6  7  17|
|      |
|1  1  3  3|
|-  -  -- --|
+4  7  11 19+

```

Type: Matrix Fraction Integer

=====

Operations on Matrices

=====

Axiom provides both left and right scalar multiplication.

```

m := matrix [ [1,2],[3,4] ]
      +1  2+
      |    |
      +3  4+

```

Type: Matrix Integer

```

4 * m * (-5)
+- 20  - 40+
|      |
+- 60  - 80+

```

Type: Matrix Integer

You can add, subtract, and multiply matrices provided, of course, that the matrices have compatible dimensions. If not, an error message is displayed.

```

n := matrix([ [1,0,-2],[-3,5,1] ])
      + 1  0  - 2+
      |      |
      +- 3  5  1 +

```

Type: Matrix Integer

This following product is defined but $n * m$ is not.

```

m * n
+- 5  10  0 +
|      |
+- 9  20  - 2+

```

Type: Matrix Integer

The operations `nrows` and `ncols` return the number of rows and columns of a matrix. You can extract a row or a column of a matrix using the operations `row` and `column`. The object returned is a Vector.

Here is the third column of the matrix `n`.

```

vec := column(n,3)

```

```
[- 2,1]
```

```
Type: Vector Integer
```

You can multiply a matrix on the left by a "row vector" and on the right by a "column vector".

```
vec * m
[1,0]
```

```
Type: Vector Integer
```

Of course, the dimensions of the vector and the matrix must be compatible or an error message is returned.

```
m * vec
[0,- 2]
```

```
Type: Vector Integer
```

The operation `inverse` computes the inverse of a matrix if the matrix is invertible, and returns "failed" if not.

This Hilbert matrix is invertible.

```
hilb := matrix([ [1/(i + j) for i in 1..3] for j in 1..3])
+1  1  1+
|-  -  -|
|2  3  4|
|   |
|1  1  1|
|-  -  -|
|3  4  5|
|   |
|1  1  1|
|-  -  -|
+4  5  6+
```

```
Type: Matrix Fraction Integer
```

```
inverse(hilb)
+ 72  - 240  180 +
|      |
|- 240  900  - 720|
|      |
+ 180  - 720  600 +
Type: Union(Matrix Fraction Integer,...)
```

This matrix is not invertible.

```
mm := matrix([ [1,2,3,4], [5,6,7,8], [9,10,11,12], [13,14,15,16] ])
+1  2  3  4 +
|      |
|5  6  7  8|
```

```

|      |
|9   10  11  12|
|      |
+13  14  15  16+

```

Type: Matrix Integer

```
inverse(mm)
"failed"
```

Type: Union("failed",...)

The operation determinant computes the determinant of a matrix provided that the entries of the matrix belong to a CommutativeRing.

The above matrix mm is not invertible and, hence, must have determinant 0.

```
determinant(mm)
0
```

Type: NonNegativeInteger

The operation trace computes the trace of a square matrix.

```
trace(mm)
34
```

Type: PositiveInteger

The operation rank computes the rank of a matrix: the maximal number of linearly independent rows or columns.

```
rank(mm)
2
```

Type: PositiveInteger

The operation nullity computes the nullity of a matrix: the dimension of its null space.

```
nullity(mm)
2
```

Type: PositiveInteger

The operation nullSpace returns a list containing a basis for the null space of a matrix. Note that the nullity is the number of elements in a basis for the null space.

```
nullSpace(mm)
[[1,- 2,1,0],[2,- 3,0,1]]
```

Type: List Vector Integer

The operation rowEchelon returns the row echelon form of a matrix. It is easy to see that the rank of this matrix is two and that its nullity is also two.

```

rowEchelon(mm)
      +1  2  3  4 +
      |      |
      |0  4  8 12|
      |      |
      |0  0  0  0|
      |      |
      +0  0  0  0 +
                                     Type: Matrix Integer

```

— domain MATRIX Matrix —

```

)abbrev domain MATRIX Matrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{Matrix} is a matrix domain where 1-based indexing is used
++ for both rows and columns.

Matrix(R) : SIG == CODE where
  R : Ring

  Row ==> Vector R
  Col ==> Vector R
  mnRow ==> 1
  mnCol ==> 1
  MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)
  MATSTOR ==> StorageEfficientMatrixOperations(R)

  SIG ==> MatrixCategory(R,Row,Col) with

    diagonalMatrix : Vector R -> $
      ++ \spad{diagonalMatrix(v)} returns a diagonal matrix where the elements
      ++ of v appear on the diagonal.

    if R has ConvertibleTo InputForm then ConvertibleTo InputForm

    if R has Field then

      inverse : $ -> Union($,"failed")
      ++ \spad{inverse(m)} returns the inverse of the matrix m.
      ++ If the matrix is not invertible, "failed" is returned.

```

```

++ Error: if the matrix is not square.

=====

MonoidRing examples

=====

MonoidRing(R,M), implements the algebra of all maps from the monoid M to the commutative ring R with finite support.

Multiplication of two maps f and g is defined to map an element c of M to the (convolution) sum over f(a)g(b) such that ab = c. Thus M can be identified with a canonical basis and the maps can also be considered as formal linear combinations of the elements in M. Scalar multiples of a basis element are called monomials. A prominent example is the class of polynomials where the monoid is a direct product of the natural numbers with pointwise addition. When M is FreeMonoid Symbol, one gets polynomials in infinitely many non-commuting variables. Another application area is representation theory of finite groups G, where modules over MonoidRing(R,G) are studied.

=====

Multiset examples

=====

The domain Multiset(R) is similar to Set(R) except that multiplicities (counts of duplications) are maintained and displayed. Use the operation multiset to create multisets from lists. All the standard operations from sets are available for multisets. An element with multiplicity greater than one has the multiplicity displayed first, then a colon, and then the element.

Create a multiset of integers.

```
s := multiset [1,2,3,4,5,4,3,2,3,4,5,6,7,4,10]
      {10,1,7,3: 3,2: 5,6,2: 2,4: 4}
      Type: Multiset PositiveInteger
```

The operation insert! adds an element to a multiset.

```
insert!(3,s)
      {10,1,7,4: 3,2: 5,6,2: 2,4: 4}
      Type: Multiset PositiveInteger
```

Use remove! to remove an element. If a third argument is present, it specifies how many instances to remove. Otherwise all instances of the element are removed. Display the resulting multiset.

```
remove!(3,s,1)
      {10,1,7,3: 3,2: 5,6,2: 2,4: 4}
      Type: Multiset PositiveInteger
```

```
remove!(5,s); s
      {10,1,7,3: 3,6,2: 2,4: 4}
      Type: Multiset PositiveInteger
```

The operation count returns the number of copies of a given value.

```
count(5,s)
      0
      Type: NonNegativeInteger
```

A second multiset.

```
t := multiset [2,2,2,-9]
      {- 9,3: 2}
      Type: Multiset Integer
```

The union of two multisets is additive.

```
U := union(s,t)
```

```
{10,1,7,3: 3,- 9,6,5: 2,4: 4}
Type: Multiset Integer
```

The `intersect` operation gives the elements that are in common, with additive multiplicity.

```
I := intersect(s,t)
{5: 2}
Type: Multiset Integer
```

The difference of `s` and `t` consists of the elements that `s` has but `t` does not. Elements are regarded as indistinguishable, so that if `s` and `t` have any element in common, the difference does not contain that element.

```
difference(s,t)
{10,1,7,3: 3,6,4: 4}
Type: Multiset Integer
```

The `symmetricDifference` is the union of `difference(s, t)` and `difference(t, s)`.

```
S := symmetricDifference(s,t)
{10,1,7,3: 3,- 9,6,4: 4}
Type: Multiset Integer
```

Check that the union of the `symmetricDifference` and the `intersect` equals the union of the elements.

```
(U = union(S,I))@Boolean
true
Type: Boolean
```

Check some inclusion relations.

```
t1 := multiset [1,2,2,3]; [t1 < t, t1 < s, t < s, t1 <= s]
[false,true,false,true]
Type: List Boolean
```

=====
MultivariatePolynomial examples
=====
```

The domain constructor `MultivariatePolynomial` is similar to `Polynomial` except that it specifies the variables to be used. `Polynomial` are available for `MultivariatePolynomial`. The abbreviation for `MultivariatePolynomial` is `MPOLY`. The type expressions

```
MultivariatePolynomial([x,y],Integer)
MPOLY([x,y],INT)
```

refer to the domain of multivariate polynomials in the variables `x` and `y` where the coefficients are restricted to be integers. The first variable specified is the main variable and the display of the polynomial reflects this.

This polynomial appears with terms in descending powers of the variable `x`.

```
m : MPOLY([x,y],INT) := (x^2 - x*y^3 +3*y)^2
      4      3 3      6      2      4      2
      x  - 2y x  + (y  + 6y)x  - 6y x + 9y
                                     Type: MultivariatePolynomial([x,y],Integer)
```

It is easy to see a different variable ordering by doing a conversion.

```
m :: MPOLY([y,x],INT)
      2 6      4      3 3      2      2      4
      x y  - 6x y  - 2x y  + 9y  + 6x y + x
                                     Type: MultivariatePolynomial([y,x],Integer)
```

You can use other, unspecified variables, by using `Polynomial` in the coefficient type of `MPOLY`.

```
p : MPOLY([x,y],POLY INT)
                                     Type: Void
```

Conversions can be used to re-express such polynomials in terms of the other variables. For example, you can first push all the variables into a polynomial with integer coefficients.

```
p :: POLY INT
      p
                                     Type: Polynomial Integer
```

Now pull out the variables of interest.

```
% :: MPOLY([a,b],POLY INT)
      p
                                     Type: MultivariatePolynomial([a,b],Polynomial Integer)
```

Restriction:

Axiom does not allow you to create types where MultivariatePolynomial is contained in the coefficient type of Polynomial. Therefore, MPOLY([x,y],POLY INT) is legal but POLY MPOLY([x,y],INT) is not.

Multivariate polynomials may be combined with univariate polynomials to create types with special structures.

```
q : UP(x, FRAC MPOLY([y,z],INT))
      Type: Void
```

This is a polynomial in x whose coefficients are quotients of polynomials in y and z.

$$(7) \quad q := (x^2 - x(z+1)/y + 2)^2$$

$$\frac{x^4 - 2zx^3 - 2x^3 + 4y^2x^2 + z^2x^2 + 2zx + 1}{y^2} - \frac{4z - 4}{y}x + 4$$

```
Type: UnivariatePolynomial(x,Fraction MultivariatePolynomial([y,z],Integer))
```

Use conversions for structural rearrangements. z does not appear in a denominator and so it can be made the main variable.

```
q :: UP(z, FRAC MPOLY([x,y],INT))
```

$$\frac{x^2}{y^2} - \frac{2yx^3 + 2x^2 - 4yx^2}{y^2} + \frac{y^2x^4 - 2yx^3 + (4y^2 + 1)x^2 - 4yx + 4y^2}{y^2}z + \frac{2}{y^2}$$

```
Type: UnivariatePolynomial(z,Fraction MultivariatePolynomial([x,y],Integer))
```

Or you can make a multivariate polynomial in x and z whose coefficients are fractions in polynomials in y.

```
q :: MPOLY([x,z], FRAC UP(y,INT))
```

$$x^4 + (-\frac{2}{y}z - \frac{2}{y})x^3 + (-\frac{1}{y^2}z + \frac{2}{y^2}z + \frac{4y^2 + 1}{y^2})x^2 + (-\frac{4}{y}z - \frac{4}{y})x + 4$$

```
Type: MultivariatePolynomial([x,z],Fraction UnivariatePolynomial(y,Integer))
```

A conversion like q :: MPOLY([x,y], FRAC UP(z,INT)) is not possible in this example because y appears in the denominator of a fraction. As you can see, Axiom provides extraordinary flexibility in the manipulation and display of expressions via its conversion facility.

— domain MPOLY MultivariatePolynomial —

```

)abbrev domain MPOLY MultivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This type is the basic representation of sparse recursive multivariate
++ polynomials whose variables are from a user specified list of symbols.
++ The ordering is specified by the position of the variable in the list.
++ The coefficient ring may be non commutative,
++ but the variables are assumed to commute.

MultivariatePolynomial(vl,R) == CODE where
  vl : List Symbol
  R : Ring

domain NSMP NewSparseMultivariatePolynomial

Based on the **PseudoRemainderSequence** package, the domain constructor **NewSparseMultivariatePolynomial** extends the constructor **SparseMultivariatePolynomial**. It also provides some additional operations related to polynomial system solving by means of triangular sets.

)abbrev domain NSUP NewSparseUnivariatePolynomial
++ Author: Marc Moreno Maza
++ Date Created: 23/07/98
++ Date Last Updated: 14/12/98
++ Description:
++ A post-facto extension for \axiomType{SUP} in order
++ to speed up operations related to pseudo-division and gcd for
++ both \axiomType{SUP} and, consequently, \axiomType{NSMP}.

NewSparseUnivariatePolynomial(R) : SIG == CODE where
  R : Ring

  NNI ==> NonNegativeInteger
  SUPR ==> SparseUnivariatePolynomial R

  SIG ==> Join(UnivariatePolynomialCategory(R),
    CoercibleTo(SUPR),RetractableTo(SUPR)) with

  fmech : (%,NNI,R,%) -> %
    ++ \axiom{fmech(p1,e,r,p2)} returns \axiom{p1 - r * x**e * p2}
    ++ where \axiom{x} is \axiom{monomial(1,1)}

  monicModulo : ($, $) -> $
    ++ \axiom{monicModulo(a,b)} returns \axiom{r} such that \axiom{r} is
    ++ reduced w.r.t. \axiom{b} and \axiom{b} divides \axiom{a - r}
    ++ where \axiom{b} is monic.

  lazyResidueClass : ($,$) -> Record(polnum:$, polden:R, power:NNI)
    ++ \axiom{lazyResidueClass(a,b)} returns \axiom{[r,c,n]} such that
    ++ \axiom{r} is reduced w.r.t. \axiom{b} and \axiom{b} divides
    ++ \axiom{c^n * a - r} where \axiom{c} is \axiom{leadingCoefficient(b)}
    ++ and \axiom{n} is as small as possible with the previous properties.

  lazyPseudoRemainder : ($,$) -> $
    ++ \axiom{lazyPseudoRemainder(a,b)} returns \axiom{r} if
    ++ \axiom{lazyResidueClass(a,b)} returns \axiom{[r,c,n]}.
    ++ This lazy pseudo-remainder is computed by means of the
    ++ fmech from NewSparseUnivariatePolynomial operation.

  lazyPseudoDivide : ($,$) -> Record(coef:R,gap:NNI,quotient:$,remainder:$)
    ++ \axiom{lazyPseudoDivide(a,b)} returns \axiom{[c,g,q,r]} such that
    ++ \axiom{c^n * a = q*b + r} and \axiom{lazyResidueClass(a,b)} returns
    ++ \axiom{[r,c,n]} where
    ++ \axiom{n + g = max(0, degree(b) - degree(a) + 1)}.

  lazyPseudoQuotient : ($,$) -> $
    ++ \axiom{lazyPseudoQuotient(a,b)} returns \axiom{q} if
    ++ \axiom{lazyPseudoDivide(a,b)} returns \axiom{[c,g,q,r]}

  if R has IntegralDomain then

```

```

subResultantsChain : ($, $) -> List $
  ++ \axiom{subResultantsChain(a,b)} returns the list of the non-zero
  ++ sub-resultants of \axiom{a} and \axiom{b} sorted by increasing
  ++ degree.

lastSubResultant : ($, $) -> $
  ++ \axiom{lastSubResultant(a,b)} returns \axiom{resultant(a,b)}
  ++ if \axiom{a} and \axiom{b} has no non-trivial gcd
  ++ in \axiom{R(-1) P}
  ++ otherwise the non-zero sub-resultant with smallest index.

extendedSubResultantGcd : ($, $) -> Record(gcd: $, coef1: $, coef2: $)
  ++ \axiom{extendedSubResultantGcd(a,b)} returns \axiom{[g,ca, cb]}
  ++ such that \axiom{g} is a gcd of \axiom{a} and \axiom{b} in
  ++ \axiom{R(-1) P} and \axiom{g = ca * a + cb * b}

halfExtendedSubResultantGcd1 : ($, $) -> Record(gcd: $, coef1: $)
  ++ \axiom{halfExtendedSubResultantGcd1(a,b)} returns \axiom{[g,ca]}

=====
None examples
=====
```

The None domain is not very useful for interactive work but it is provided nevertheless for completeness of the Axiom type system.

Probably the only place you will ever see it is if you enter an empty list with no type information.

```
[ ]
[]
```

Type: List None

Such an empty list can be converted into an empty list of any other type.

```
[ ] :: List Float
[]
```

Type: List Float

If you wish to produce an empty list of a particular type directly, such as List NonNegativeInteger, do it this way.

```
[ ]$List(NonNegativeInteger)
[]
```

Type: List NonNegativeInteger

NottinghamGroup examples

=====

n

If F is a finite field with p elements, then we may form the group of all formal power series $\{t(1+a_1t+a_2t^2+\dots)\}$ where $u(0)=0$ and $u(0)=1$ and a_i is an element of F .

i

The group operation is substitution (composition).
This is called the Nottingham Group.

The Nottingham Group is the projective limit of finite p -groups.
Every finite p -group can be embedded in the Nottingham Group.

NumericalIntegrationProblem examples

=====

NumericalIntegrationProblem is a domain for the representation of Numerical Integration problems for use by ANNA.

The representation is a Union of two record types - one for integration of a function of one variable:

```
Record(var:Symbol,
       fn:Expression DoubleFloat,
       range:Segment OrderedCompletion DoubleFloat,
       abserr:DoubleFloat,
       relerr:DoubleFloat)
```

and one for multivariate integration:

```
Record(fn:Expression DoubleFloat,
       range:List Segment OrderedCompletion DoubleFloat,
       abserr:DoubleFloat,
       relerr:DoubleFloat)
```

Chapter 16

Chapter O

domain OCT Octonion

The octonions have the following multiplication table:

1	i	j	k	E	I	J	K
i	-1	k	$-j$	I	$-E$	$-K$	J
j	$-k$	-1	i	J	K	$-E$	$-I$
k	j	$-i$	-1	K	$-J$	I	$-E$
E	$-I$	$-J$	$-K$	-1	i	j	k
I	E	$-K$	J	$-i$	-1	$-k$	j
J	K	E	$-I$	$-j$	k	-1	$-i$
K	$-J$	I	E	$-k$	$-j$	i	-1

There are 3 different kinds of associativity. An algebra is

- **power-associative** if the subalgebra generated by any one element is associative. That is, given any element e then $e * (e * e) = (e * e) * e$.
- **alternative** if the subalgebra generated by any two elements is associative. That is, given any two elements, a and b then $a * (a * b) = (a * a) * b$ and $a * (b * a) = (a * b) * a$ and $b * (a * a) = (b * a) * a$.
- **associative** if the subalgebra generated by any three elements is associative. That is, given any three elements a , b , and c then $a * (b * c) = (a * b) * c$.

The Octonions are power-associative and alternative but not associative, since $I * (J * K) \neq (I * J) * K$.

=====

Octonion examples

=====

The Octonions, also called the Cayley-Dixon algebra, defined over a commutative ring are an eight-dimensional non-associative algebra. Their construction from quaternions is similar to the construction of quaternions from complex numbers.

As Octonion creates an eight-dimensional algebra, you have to give eight components to construct an octonion.

```

oci1 := octon(1,2,3,4,5,6,7,8)
      1 + 2i + 3j + 4k + 5E + 6I + 7J + 8K
                        Type: Octonion Integer

oci2 := octon(7,2,3,-4,5,6,-7,0)
      7 + 2i + 3j - 4k + 5E + 6I - 7J
                        Type: Octonion Integer

```

Or you can use two quaternions to create an octonion.

```

oci3 := octon(quatern(-7,-12,3,-10), quatern(5,6,9,0))

```

```
- 7 - 12i + 3j - 10k + 5E + 6I + 9J
Type: Octonion Integer
```

You can easily demonstrate the non-associativity of multiplication.

```
(oci1 * oci2) * oci3 - oci1 * (oci2 * oci3)
2696i - 2928j - 4072k + 16E - 1192I + 832J + 2616K
Type: Octonion Integer
```

As with the quaternions, we have a real part, the imaginary parts i, j, k , and four additional imaginary parts E, I, J and K . These parts correspond to the canonical basis $(1, i, j, k, E, I, J, K)$.

For each basis element there is a component operation to extract the coefficient of the basis element for a given octonion.

```
[real oci1, imagi oci1, imagj oci1, imagk oci1, _
imagE oci1, imagI oci1, imagJ oci1, imagK oci1]
[1,2,3,4,5,6,7,8]
Type: List PositiveInteger
```

A basis with respect to the quaternions is given by $(1, E)$. However, you might ask, what then are the commuting rules? To answer this, we create some generic elements.

We do this in Axiom by simply changing the ground ring from Integer to Polynomial Integer.

```
q : Quaternion Polynomial Integer := quatern(q1, qi, qj, qk)
q1 + qi i + qj j + qk k
Type: Quaternion Polynomial Integer
```

```
E : Octonion Polynomial Integer := octon(0,0,0,0,1,0,0,0)
E
Type: Octonion Polynomial Integer
```

Note that quaternions are automatically converted to octonions in the obvious way.

```
q * E
q1 E + qi I + qj J + qk K
Type: Octonion Polynomial Integer
```

```
E * q
q1 E - qi I - qj J - qk K
Type: Octonion Polynomial Integer
```

```
q * 1$(Octonion Polynomial Integer)
q1 + qi i + qj j + qk k
Type: Octonion Polynomial Integer
```

```

1$(Octonion Polynomial Integer) * q
q1 + qi i + qj j + qk k
Type: Octonion Polynomial Integer

```

Finally, we check that the norm, defined as the sum of the squares of the coefficients, is a multiplicative map.

```

o : Octonion Polynomial Integer := octon(o1, oi, oj, ok, oE, oI, oJ, oK)
o1 + oi i + oj j + ok k + oE E + oI I + oJ J + oK K
Type: Octonion Polynomial Integer

```

```

norm o
      2      2      2      2      2      2      2      2
ok  + oj  + oi  + oK  + oJ  + oI  + oE  + o1
Type: Polynomial Integer

```

```

p : Octonion Polynomial Integer := octon(p1, pi, pj, pk, pE, pI, pJ, pK)
p1 + pi i + pj j + pk k + pE E + pI I + pJ J + pK K
Type: Octonion Polynomial Integer

```

Since the result is 0, the norm is multiplicative.

```

norm(o*p)-norm(p)*norm(o)
0
Type: Polynomial Integer

```

)abbrev domain OCT Octonion
++ Author: R. Wisbauer, J. Grabmeier
++ Date Created: 05 September 1990
++ Date Last Updated: 20 September 1990
++ References: I.L Kantor, A.S. Solodovnikov:
++ Hypercomplex Numbers, Springer Verlag Heidelberg, 1989,
++ ISBN 0-387-96980-2
++ Description:
++ Octonion implements octonions (Cayley-Dixon algebra) over a
++ commutative ring, an eight-dimensional non-associative
++ algebra, doubling the quaternions in the same way as doubling
++ the complex numbers to get the quaternions
++ the main constructor function is octon which takes 8
++ arguments: the real part, the i imaginary part, the j
++ imaginary part, the k imaginary part, (as with quaternions)
++ and in addition the imaginary parts E, I, J, K.

=====

OneDimensionalArray examples

=====

The OneDimensionalArray domain is used for storing data in a one-dimensional indexed data structure. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain. Each array has a fixed length specified by the user and arrays are not extensible. The indexing of

one-dimensional arrays is one-based. This means that the "first" element of an array is given the index 1.

To create a one-dimensional array, apply the operation `oneDimensionalArray` to a list.

```
oneDimensionalArray [i**2 for i in 1..10]
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray PositiveInteger
```

Another approach is to first create `a`, a one-dimensional array of 10 0's. `OneDimensionalArray` has the convenient abbreviation `ARRAY1`.

```
a : ARRAY1 INT := new(10,0)
[0,0,0,0,0,0,0,0,0,0]
Type: OneDimensionalArray Integer
```

Set each *i*-th element to *i*, then display the result.

```
for i in 1..10 repeat a[i] := i; a
[1,2,3,4,5,6,7,8,9,10]
Type: OneDimensionalArray Integer
```

Square each element by mapping the function `i +-> i^2` onto each element.

```
map!(i +-> i ** 2, a); a
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray Integer
```

Reverse the elements in place.

```
reverse! a
[100,81,64,49,36,25,16,9,4,1]
Type: OneDimensionalArray Integer
```

Swap the 4th and 5th element.

```
swap!(a,4,5); a
[100,81,64,36,49,25,16,9,4,1]
Type: OneDimensionalArray Integer
```

Sort the elements in place.

```
sort! a
[1,4,9,16,25,36,49,64,81,100]
Type: OneDimensionalArray Integer
```

Create a new one-dimensional array `b` containing the last 5 elements of `a`.

```
b := a(6..10)
```

```
[36,49,64,81,100]
Type: OneDimensionalArray Integer
```

Replace the first 5 elements of a with those of b.

```
copyInto!(a,b,1)
[36,49,64,81,100,36,49,64,81,100]
Type: OneDimensionalArray Integer
```

=====

Operator examples

=====

Given any ring R, the ring of the Integer-linear operators over R is called Operator(R). To create an operator over R, first create a basic operator using the operation operator, and then convert it to Operator(R) for the R you want.

We choose R to be the two by two matrices over the integers.

```

R := SQMATRIX(2, INT)

```

```
SquareMatrix(2,Integer)
Type: Domain
```

Create the operator tilde on R.

```
t := operator("tilde") :: OP(R)
tilde
Type: Operator SquareMatrix(2,Integer)
```

Since Operator is unexposed we must either package-call operations from it, or expose it explicitly. For convenience we will do the latter.

Expose Operator.

```
)set expose add constructor Operator
```

To attach an evaluation function (from R to R) to an operator over R, use evaluate(op, f) where op is an operator over R and f is a function $R \rightarrow R$. This needs to be done only once when the operator is defined. Note that f must be Integer-linear (that is, $f(ax+y) = a f(x) + f(y)$ for any integer a, and any x and y in R).

We now attach the transpose map to the above operator t.

```
evaluate(t, m +-> transpose m)
tilde
Type: Operator SquareMatrix(2,Integer)
```

Operators can be manipulated formally as in any ring: + is the pointwise addition and * is composition. Any element x of R can be converted to an operator op(x) over R, and the evaluation function of op(x) is left-multiplication by x.

Multiplying on the left by this matrix swaps the two rows.

```
s : R := matrix [ [0, 1], [1, 0] ]
+0 1+
|   |
+1 0+
Type: SquareMatrix(2,Integer)
```

Can you guess what is the action of the following operator?

```
rho := t * s
+0 1+
tilde|   |
+1 0+
Type: Operator SquareMatrix(2,Integer)
```

Hint: applying rho four times gives the identity, so rho⁴-1 should

return 0 when applied to any two by two matrix.

```
z := rho**4 - 1
      +0 1+      +0 1+      +0 1+      +0 1+
    - 1 + tilde|  |tilde|  |tilde|  |tilde|  |
      +1 0+      +1 0+      +1 0+      +1 0+
                                Type: Operator SquareMatrix(2,Integer)
```

Now check with this matrix.

```
m:R := matrix [ [1, 2], [3, 4] ]
      +1 2+
      |  |
      +3 4+
                                Type: SquareMatrix(2,Integer)
```

```
z m
      +0 0+
      |  |
      +0 0+
                                Type: SquareMatrix(2,Integer)
```

As you have probably guessed by now, rho acts on matrices by rotating the elements clockwise.

```
rho m
      +3 1+
      |  |
      +4 2+
                                Type: SquareMatrix(2,Integer)
```

```
rho rho m
      +4 3+
      |  |
      +2 1+
                                Type: SquareMatrix(2,Integer)
```

```
(rho^3) m
      +2 4+
      |  |
      +1 3+
                                Type: SquareMatrix(2,Integer)
```

Do the swapping of rows and transposition commute? We can check by computing their bracket.

```
b := t * s - s * t
      +0 1+      +0 1+
    - |  |tilde + tilde|  |
      +1 0+      +1 0+
```

Type: Operator SquareMatrix(2,Integer)

Now apply it to m.

b m

$$\begin{pmatrix} +1 & -3 \\ +3 & -1 \end{pmatrix}$$

Type: SquareMatrix(2,Integer)

Next we demonstrate how to define a differential operator on a polynomial ring.

This is the recursive definition of the n-th Legendre polynomial.

L n ==

n = 0 => 1

n = 1 => x

(2*n-1)/n * x * L(n-1) - (n-1)/n * L(n-2)

Type: Void

Create the differential operator d/dx on polynomials in x over the rational numbers.

dx := operator("D") :: OP(POLY FRAC INT)

D

Type: Operator Polynomial Fraction Integer

Now attach the map to it.

evaluate(dx, p +-> D(p, 'x))

D

Type: Operator Polynomial Fraction Integer

This is the differential equation satisfied by the n-th Legendre polynomial.

E n == (1 - x**2) * dx**2 - 2 * x * dx + n*(n+1)

Type: Void

Now we verify this for n = 15. Here is the polynomial.

L 15

$$\frac{9694845}{2048}x^{15} - \frac{35102025}{2048}x^{13} + \frac{50702925}{2048}x^{11} - \frac{37182145}{2048}x^9 + \frac{14549535}{2048}x^7$$

+

$$-\frac{2909907}{2048}x^5 + \frac{255255}{2048}x^3 - \frac{6435}{2048}x$$

Type: Polynomial Fraction Integer

Here is the operator.

```
E 15
  240 - 2x D - (x - 1)D
Type: Operator Polynomial Fraction Integer
```

Here is the evaluation.

```
(E 15)(L 15)
  0
Type: Polynomial Fraction Integer
```

OrderedFreeMonoid examples

The free monoid on a set S is the monoid of finite products of the form $\text{reduce}(*,[s_i ** n_i])$ where the s_i 's are in S , and the n_i 's are non-negative integers. The multiplication is not commutative. For two elements x and y the relation $x < y$ holds if either $\text{length}(x) < \text{length}(y)$ holds or if these lengths are equal and if x is smaller than y w.r.t. the lexicographical ordering induced by S . This domain inherits implementation from `FreeMonoid`.

```
m1:=(x*y*y*z)$OFMONOID(Symbol)
```

```
m2:=(x*y)$OFMONOID(Symbol)
```

```
lquo(m1,m2)
```

```
m3:=(y*y)$OFMONOID(Symbol)
```

```
div(m1,m2)
```

```
div(m1,m3)
```

```
m4:=(y^3)$OFMONOID(Symbol)
```

```
div(m1,m4)
```

Build the non-commutative algebra $h=k[x,y]$ and then make computations in h using some predefined rules for x and y . For example, giving

```
x*y*x=y*x*y
x*x=a*x+b
y*y=a*y+b
```

where a and b are generic elements of k .

Then reduce the polynomials in x and y according to the previous rules. That is, given

```
(x+y)^2  (= x^2+x*y+y*x+y^2)
```

should reduce to

```
a*(x+y)+2*b+x*y+y*x
```

We can reduce the clutter of the work by defining macros for the types of the domains we need to create. So first we create those macros.

We create generic elements of k . First we define a macro for the domain of ordered variables (OVAR is OrderedVariableList)

```
C ==> OVAR [a,b]
```

Next we define a macro for the commutative field domain $k = Q[a,b]$ where Q is Fraction(Integer) and SMP is SparseMultivariatePolynomials

```
K ==> SMP(FRAC INT,C)
```

Now we need some non-commutative variables so we create a macro for that.

```
V ==> OVAR [x,y]
```

And now we need to define the non-commutative algebra $k=k[x,y]$. We use the domain XDistributedPolynomial (XDPOLY) as a macro.

```
H ==> XDPOLY(V,K)
```

The non-commutative variables are in an Ordered Free Monoid

```
M ==> OFMONOID V
```

We have three rules to apply. So we create a function that examines one term. Substitution rules are applied to words from the monoid over the variables and return polynomials. If any rule matches we construct the substitution, create a new monomial term and return it.

```
subs(w:M):H ==
  -- x*y*x = y*x*y
  n1:=lquo(w,(x::V*y::V*x::V)$M)$M
  n1 case "failed" => monom(w,1)$H
  -- x*x = a*x+b
  n2:=lquo(w,(x::V^2)$M)$M
  n2 case "failed" => monom(w,1)$H
  -- y*y = a*y+b
  n3:=lquo(w,(y::V^2)$M)$M
  n3 case "failed" => monom(w,1)$H
  monom(n3,1)$H * (a::K*y::V+b::K)$M * monom(n3,1)$H
  monom(n2,1)$H * (a::K*x::V+b::K)$H * monom(n2,1)$H
  monom(n1,1)$H * (y::V*x::V*y::V)$H * monom(n1,1)$H
```

We apply these rules to a term, remembering the coefficient

```
newterm(x:Record(k:M,c:K)):H == x.c*subs(x,k)
```

And now we create a function to reconstruct the polynomial term by term.

```
newpoly(t:H):H == reduce(+,map(newterm,listOfTerms(t)))
```

For example,

```
p1:(x::V+y::V)$H^2
newpoly(p1)
p2:=(x::V+y::V)$H^3
pNew:=newpoly(p2)
```

But the rules should be applied more than once so we create a function to iterate the rules until nothing changes.

```
reduce(p:H):H ==
```

```

p2 := newpoly(p)
p3 := newpoly(p2)
while p3 ~= p2 repeat
  p2 := p3
  p3 := newpoly(p2)
p3

```

And we can see it work

```

reduce(p2)

```

=====

OrderedVariableList examples

=====

The domain OrderedVariableList provides symbols which are restricted to a particular list and have a definite ordering. Those two features are specified by a List Symbol object that is the argument to the domain.

This is a sample ordering of three symbols.

```

ls:List Symbol:=['x','a','z']
[x,a,z]

```

Type: List Symbol

Let's build the domain

```
Z:=OVAR ls
  OrderedVariableList [x,a,z]
                                Type: Domain
```

How many variables does it have?

```
size()$Z
3
                                Type: NonNegativeInteger
```

They are (in the imposed order)

```
lv:=[index(i::PI)$Z for i in 1..size()$Z]
    [x,a,z]
                                Type: List OrderedVariableList [x,a,z]
```

Check that the ordering is right

```
sorted?(>,lv)
true
                                Type: Boolean
```

See Also:

OrderlyDifferentialPolynomial examples
=====

```

Many systems of differential equations may be transformed to equivalent

systems of ordinary differential equations where the equations are expressed polynomially in terms of the unknown functions. In Axiom, the domain constructors `OrderlyDifferentialPolynomial` (abbreviated `ODPOL`) and `SequentialDifferentialPolynomial` (abbreviation `SDPOL`) implement two domains of ordinary differential polynomials over any differential ring. In the simplest case, this differential ring is usually either the ring of integers, or the field of rational numbers. However, Axiom can handle ordinary differential polynomials over a field of rational functions in a single indeterminate.

The two domains `ODPOL` and `SDPOL` are almost identical, the only difference being the choice of a different ranking, which is an ordering of the derivatives of the indeterminates. The first domain uses an orderly ranking, that is, derivatives of higher order are ranked higher, and derivatives of the same order are ranked alphabetically. The second domain uses a sequential ranking, where derivatives are ordered first alphabetically by the differential indeterminates, and then by order. A more general domain constructor, `DifferentialSparseMultivariatePolynomial` (abbreviation `DSMP`) allows both a user-provided list of differential indeterminates as well as a user-defined ranking. We shall illustrate `ODPOL(FRAC INT)`, which constructs a domain of ordinary differential polynomials in an arbitrary number of differential indeterminates with rational numbers as coefficients.

```
dpol:= ODPOL(FRAC INT)
      OrderlyDifferentialPolynomial Fraction Integer
                        Type: Domain
```

A differential indeterminate `w` may be viewed as an infinite sequence of algebraic indeterminates, which are the derivatives of `w`. To facilitate referencing these, Axiom provides the operation `makeVariable` to convert an element of type `Symbol` to a map from the natural numbers to the differential polynomial ring.

```
w := makeVariable('w)$dpol
    theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)

z := makeVariable('z)$dpol
    theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fifth derivative of `w` can be obtained by applying the map `w` to the number 5. Note that the order of differentiation is given as a subscript (except when the order is 0).

```
w.5
  w
  5
                                Type: OrderlyDifferentialPolynomial Fraction Integer
```

w 0
w

Type: OrderlyDifferentialPolynomial Fraction Integer

The first five derivatives of z can be generated by a list.

[z.i for i in 1..5]
[z ,z ,z ,z ,z]
1 2 3 4 5

Type: List OrderlyDifferentialPolynomial Fraction Integer

The usual arithmetic can be used to form a differential polynomial from the derivatives.

f:= w.4 - w.1 * w.1 * z.3
2
w - w z
4 1 3

Type: OrderlyDifferentialPolynomial Fraction Integer

g:=(z.1)**3 * (z.2)**2 - w.2
3 2
z z - w
1 2 2

Type: OrderlyDifferentialPolynomial Fraction Integer

The operation D computes the derivative of any differential polynomial.

D(f)
2
w - w z - 2w w z
5 1 4 1 2 3

Type: OrderlyDifferentialPolynomial Fraction Integer

The same operation can compute higher derivatives, like the fourth derivative.

D(f,4)
2 2
w - w z - 8w w z + (- 12w w - 12w)z - 2w z w
8 1 7 1 2 6 1 3 2 5 1 3 5
+
2
(- 8w w - 24w w)z - 8w z w - 6w z
1 4 2 3 4 2 3 4 3 3

Type: OrderlyDifferentialPolynomial Fraction Integer

The operation makeVariable creates a map to facilitate referencing the derivatives of f, similar to the map w.

```
df:=makeVariable(f)$dpol
  theMap(DPOLCAT-;makeVariable;AM;17!0,0)
Type: (NonNegativeInteger -> OrderlyDifferentialPolynomial Fraction Integer)
```

The fourth derivative of f may be referenced easily.

```
df.4
      2
      w  - w  z  - 8w w z  + (- 12w w  - 12w  )z  - 2w z w
      8    1 7    1 2 6    1 3    2 5    1 3 5
+
      2
      (- 8w w  - 24w w )z  - 8w z w  - 6w  z
      1 4    2 3 4    2 3 4    3 3
Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation order returns the order of a differential polynomial, or the order in a specified differential indeterminate.

```
order(g)
2
Type: PositiveInteger

order(g, 'w)
2
Type: PositiveInteger
```

The operation differentialVariables returns a list of differential indeterminates occurring in a differential polynomial.

```
differentialVariables(g)
[z,w]
Type: List Symbol
```

The operation degree returns the degree, or the degree in the differential indeterminate specified.

```
degree(g)
2 3
z z
2 1
Type: IndexedExponents OrderlyDifferentialVariable Symbol

degree(g, 'w)
1
Type: PositiveInteger
```

The operation weights returns a list of weights of differential monomials appearing in differential polynomial, or a list of weights in a specified differential indeterminate.

```
weights(g)
[7,2]
Type: List NonNegativeInteger
```

```
weights(g,'w')
[2]
Type: List NonNegativeInteger
```

The operation `weight` returns the maximum weight of all differential monomials appearing in the differential polynomial.

```
weight(g)
7
Type: PositiveInteger
```

A differential polynomial is isobaric if the weights of all differential monomials appearing in it are equal.

```
isobaric?(g)
false
Type: Boolean
```

To substitute differentially, use `eval`. Note that we must coerce `'w` to `Symbol`, since in ODPOL, differential indeterminates belong to the domain `Symbol`. Compare this result to the next, which substitutes algebraically (no substitution is done since `w.0` does not appear in `g`).

```
eval(g,['w::Symbol'],[f])
      2          2          3 2
    - w  + w  z  + 4w w z  + (2w w  + 2w )z  + z  z
      6      1 5      1 2 4      1 3      2 3      1 2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
eval(g,variables(w.0),[f])
      3 2
    z  z  - w
    1 2      2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

Since `OrderlyDifferentialPolynomial` belongs to `PolynomialCategory`, all the operations defined in the latter category, or in packages for the latter category, are available.

```
monomials(g)
      3 2
    [z  z  , - w ]
      1 2      2
Type: List OrderlyDifferentialPolynomial Fraction Integer
```

```
variables(g)
  [z ,w ,z ]
    2 2 1
Type: List OrderlyDifferentialVariable Symbol
```

```
gcd(f,g)
  1
Type: OrderlyDifferentialPolynomial Fraction Integer
```

```
groebner([f,g])
      2      3 2
[w - w z ,z z - w ]
  4      1 3 1 2      2
Type: List OrderlyDifferentialPolynomial Fraction Integer
```

The next three operations are essential for elimination procedures in differential polynomial rings. The operation leader returns the leader of a differential polynomial, which is the highest ranked derivative of the differential indeterminates that occurs.

```
lg:=leader(g)
  z
  2
Type: OrderlyDifferentialVariable Symbol
```

The operation separant returns the separant of a differential polynomial, which is the partial derivative with respect to the leader.

```
sg:=separant(g)
  3
2z z
 1 2
Type: OrderlyDifferentialPolynomial Fraction Integer
```

The operation initial returns the initial, which is the leading coefficient when the given differential polynomial is expressed as a polynomial in the leader.

```
ig:=initial(g)
  3
z
 1
Type: OrderlyDifferentialPolynomial Fraction Integer
```

Using these three operations, it is possible to reduce f modulo the differential ideal generated by g . The general scheme is to first reduce the order, then reduce the degree in the leader. First, eliminate $z.3$ using the derivative of g .

```
g1 := D g
```

$$2z_1^3 z_2^2 z_3^3 - w_1^2 + 3z_1^2 z_2^3$$

Type: OrderlyDifferentialPolynomial Fraction Integer

Find its leader.

```
lg1:= leader g1
z
3
```

Type: OrderlyDifferentialVariable Symbol

Differentiate f partially with respect to this leader.

```
pdf:=D(f, lg1)
2
- w
1
```

Type: OrderlyDifferentialPolynomial Fraction Integer

Compute the partial remainder of f with respect to g.

```
prf:=sg * f- pdf * g1
3      2      2 2 3
2z z w - w w + 3w z z
1 2 4 1 3 1 1 2
```

Type: OrderlyDifferentialPolynomial Fraction Integer

Note that high powers of lg still appear in prf. Compute the leading coefficient of prf as a polynomial in the leader of g.

```
lcf:=leadingCoefficient univariate(prf, lg)
2 2
3w z
1 1
```

Type: OrderlyDifferentialPolynomial Fraction Integer

Finally, continue eliminating the high powers of lg appearing in prf to obtain the (pseudo) remainder of f modulo g and its derivatives.

```
ig * prf - lcf * g * lg
6      2 3      2 2
2z z w - w z w + 3w z w z
1 2 4 1 1 3 1 1 2 2
```

Type: OrderlyDifferentialPolynomial Fraction Integer

OrderlyDifferentialVariable examples

=====

OrderlyDifferentialVariable adds a commonly used orderly ranking to the set of derivatives of an ordered list of differential indeterminates. An orderly ranking is a ranking $<$ of the derivatives with the property that for two derivatives u and v , $u < v$ if the order of u is less than that of v .

This domain belongs to DifferentialVariableCategory. It defines `weight` to be just `order`, and it defines an orderly ranking $<$ on derivatives u via the lexicographic order on the pair $(\text{order}(u), \text{variable}(u))$.

)abbrev domain **OUTFORM** **OutputForm**

```

++ Author: SMW March/88
++ Description:
++ This domain is used to create and manipulate mathematical expressions
++ for output. It is intended to provide an insulating layer between
++ the expression rendering software (for example, FORTRAN or TeX) and
++ the output coercions in the various domains.

OutputForm() : SIG == CODE where

SIG ==> SetCategory with

print : $ -> Void
++ print(u) prints the form u.

message : String -> $
++ message(s) creates an form with no string quotes
++ from string s.

messagePrint : String -> Void
++ messagePrint(s) prints s without string quotes. Note:
++ \spad{messagePrint(s)} is equivalent to \spad{print message(s)}.

--% Creation of atomic forms

outputForm : Integer -> $
++ outputForm(n) creates an form for integer n.

outputForm : Symbol -> $
++ outputForm(s) creates an form for symbol s.

outputForm : String -> $
++ outputForm(s) creates an form for string s.

outputForm : DoubleFloat -> $
++ outputForm(sf) creates an form for small float sf.

empty : () -> $
++ empty() creates an empty form.

--% Sizings

width : $ -> Integer
++ width(f) returns the width of form f (an integer).

height : $ -> Integer
++ height(f) returns the height of form f (an integer).

width : -> Integer
++ width() returns the width of the display area (an integer).

```

```

height : -> Integer
  ++ height() returns the height of the display area (an integer).

subHeight : $ -> Integer
  ++ subHeight(f) returns the height of form f below the base line.

superHeight : $ -> Integer
  ++ superHeight(f) returns the height of form f above the base line.

--% Space manipulations

hspace : Integer -> $
  ++ hspace(n) creates white space of width n.

vspace : Integer -> $
  ++ vspace(n) creates white space of height n.

rspace : (Integer,Integer) -> $
  ++ rspace(n,m) creates rectangular white space, n wide by m high.

--% Area adjustments

left : ($,Integer) -> $
  ++ left(f,n) left-justifies form f within space of width n.

right : ($,Integer) -> $
  ++ right(f,n) right-justifies form f within space of width n.

center : ($,Integer) -> $
  ++ center(f,n) centers form f within space of width n.

left : $ -> $
  ++ left(f) left-justifies form f in total space.

right : $ -> $
  ++ right(f) right-justifies form f in total space.

center : $ -> $
  ++ center(f) centers form f in total space.

--% Area manipulations

hconcat : ($,$) -> $
  ++ hconcat(f,g) horizontally concatenate forms f and g.

vconcat : ($,$) -> $
  ++ vconcat(f,g) vertically concatenates forms f and g.

hconcat : List $ -> $
  ++ hconcat(u) horizontally concatenates all forms in list u.

```

```

vconcat : List $ -> $
  ++ vconcat(u) vertically concatenates all forms in list u.

--% Application formers

prefix : ($, List $) -> $
  ++ prefix(f,l) creates a form depicting the n-ary prefix
  ++ application of f to a tuple of arguments given by list l.

infix : ($, List $) -> $
  ++ infix(f,l) creates a form depicting the n-ary application
  ++ of infix operation f to a tuple of arguments l.

infix : ($, $, $) -> $
  ++ infix(op, a, b) creates a form which prints as: a op b.

postfix : ($, $) -> $
  ++ postfix(op, a) creates a form which prints as: a op.

infix? : $ -> Boolean
  ++ infix?(op) returns true if op is an infix operator,
  ++ and false otherwise.

elt : ($, List $) -> $
  ++ elt(op,l) creates a form for application of op
  ++ to list of arguments l.

--% Special forms

string : $ -> $
  ++ string(f) creates f with string quotes.

label : ($, $) -> $
  ++ label(n,f) gives form f an equation label n.

box : $ -> $
  ++ box(f) encloses f in a box.

matrix : List List $ -> $
  ++ matrix(llf) makes llf (a list of lists of forms) into
  ++ a form which displays as a matrix.

zag : ($, $) -> $
  ++ zag(f,g) creates a form for the continued fraction form for f over g.

root : $ -> $
  ++ root(f) creates a form for the square root of form f.

root : ($, $) -> $

```

```

++ root(f,n) creates a form for the nth root of form f.

over : ($, $) -> $
++ over(f,g) creates a form for the vertical fraction of f over g.

slash : ($, $) -> $
++ slash(f,g) creates a form for the horizontal fraction of f over g.

assign : ($, $) -> $
++ assign(f,g) creates a form for the assignment \spad{f := g}.

rarrow : ($, $) -> $
++ rarrow(f,g) creates a form for the mapping \spad{f -> g}.

differentiate : ($, NonNegativeInteger) -> $
++ differentiate(f,n) creates a form for the nth derivative of f,
++ for example, \spad{f'}, \spad{f''}, \spad{f'''},
++ "f super \spad{iv}".

binomial : ($, $) -> $
++ binomial(n,m) creates a form for the binomial coefficient of n and m.

--% Scripts

sub : ($, $) -> $
++ sub(f,n) creates a form for f subscripted by n.

super : ($, $) -> $
++ super(f,n) creates a form for f superscripted by n.

presub : ($, $) -> $
++ presub(f,n) creates a form for f presubscripted by n.

presuper : ($, $) -> $
++ presuper(f,n) creates a form for f presuperscripted by n.

scripts : ($, List $) -> $
++ \spad{scripts(f, [sub, super, presuper, presub])}
++ creates a form for f with scripts on all 4 corners.

supersub : ($, List $) -> $
++ supersub(a,[sub1,super1,sub2,super2,...])
++ creates a form with each subscript aligned
++ under each superscript.

--% Diacritical marks

quote : $ -> $
++ quote(f) creates the form f with a prefix quote.

```

```

dot : $ -> $
  ++ dot(f) creates the form with a one dot overhead.

dot : ($, NonNegativeInteger) -> $
  ++ dot(f,n) creates the form f with n dots overhead.

prime : $ -> $
  ++ prime(f) creates the form f followed by a suffix prime (single quote).

prime : ($, NonNegativeInteger) -> $
  ++ prime(f,n) creates the form f followed by n primes.

overbar : $ -> $
  ++ overbar(f) creates the form f with an overbar.

overlabel : ($, $) -> $
  ++ overlabel(x,f) creates the form f with "x overbar" over the top.

--% Plexes

sum : ($) -> $
  ++ sum(expr) creates the form prefixing expr by a capital sigma.

sum : ($, $) -> $
  ++ sum(expr,lowerlimit) creates the form prefixing expr by
  ++ a capital sigma with a lowerlimit.

sum : ($, $, $) -> $
  ++ sum(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ a capital sigma with both a lowerlimit and upperlimit.

prod : ($) -> $
  ++ prod(expr) creates the form prefixing expr by a capital pi.

prod : ($, $) -> $
  ++ prod(expr,lowerlimit) creates the form prefixing expr by
  ++ a capital pi with a lowerlimit.

prod : ($, $, $) -> $
  ++ prod(expr,lowerlimit,upperlimit) creates the form prefixing expr by
  ++ a capital pi with both a lowerlimit and upperlimit.

int : ($) -> $
  ++ int(expr) creates the form prefixing expr with an integral sign.

int : ($, $) -> $
  ++ int(expr,lowerlimit) creates the form prefixing expr by an
  ++ integral sign with a lowerlimit.

int : ($, $, $) -> $

```

```

++ int(expr,lowerlimit,upperlimit) creates the form prefixing expr by
++ an integral sign with both a lowerlimit and upperlimit.

--% Matchfix forms

brace : $ -> $
++ brace(f) creates the form enclosing f in braces (curly brackets).

brace : List $ -> $
++ brace(lf) creates the form separating the elements of lf
++ by commas and encloses the result in curly brackets.

bracket : $ -> $
++ bracket(f) creates the form enclosing f in square brackets.

bracket : List $ -> $
++ bracket(lf) creates the form separating the elements of lf
++ by commas and encloses the result in square brackets.

paren : $ -> $
++ paren(f) creates the form enclosing f in parentheses.

paren : List $ -> $
++ paren(lf) creates the form separating the elements of lf
++ by commas and encloses the result in parentheses.

--% Separators for aggregates

pile : List $ -> $
++ pile(l) creates the form consisting of the elements of l which
++ displays as a pile, the elements begin on a new line and
++ are indented right to the same margin.

commaSeparate : List $ -> $
++ commaSeparate(l) creates the form separating the elements of l
++ by commas.

semicolonSeparate : List $ -> $
++ semicolonSeparate(l) creates the form separating the elements of l
++ by semicolons.

blankSeparate : List $ -> $
++ blankSeparate(l) creates the form separating the elements of l
++ by blanks.

--% Specific applications

"=" : ($, $) -> $
++ f = g creates the equivalent infix form.

```

```

"^=" : ($, $) -> $
  ++ f ^= g creates the equivalent infix form.

"<" : ($, $) -> $
  ++ f < g creates the equivalent infix form.

">" : ($, $) -> $
  ++ f > g creates the equivalent infix form.

"<=" : ($, $) -> $
  ++ f <= g creates the equivalent infix form.

">=" : ($, $) -> $
  ++ f >= g creates the equivalent infix form.

"+" : ($, $) -> $
  ++ f + g creates the equivalent infix form.

"-" : ($, $) -> $
  ++ f - g creates the equivalent infix form.

"- " : ($) -> $
  ++ - f creates the equivalent prefix form.

"*" : ($, $) -> $
  ++ f * g creates the equivalent infix form.

"/" : ($, $) -> $
  ++ f / g creates the equivalent infix form.

"**" : ($, $) -> $
  ++ f ** g creates the equivalent infix form.

"div" : ($, $) -> $
  ++ f div g creates the equivalent infix form.

"rem" : ($, $) -> $
  ++ f rem g creates the equivalent infix form.

"quo" : ($, $) -> $
  ++ f quo g creates the equivalent infix form.

"exquo" : ($, $) -> $
  ++ exquo(f,g) creates the equivalent infix form.

"and" : ($, $) -> $
  ++ f and g creates the equivalent infix form.

"or" : ($, $) -> $
  ++ f or g creates the equivalent infix form.

```

```

"not" : ($) -> $
  ++ not f creates the equivalent prefix form.

SEGMENT : ($,$) -> $
  ++ SEGMENT(x,y) creates the infix form: \spad{x..y}.

SEGMENT : ($) -> $
  ++ SEGMENT(x) creates the prefix form: \spad{x..}.

```

```

L      ==> List
RN     ==> Fraction Integer
ST     ==> Stream

SIG ==> QuotientFieldCategory(PADIC) with

approximate : (%,I) -> RN
++ \spad{approximate(x,n)} returns a rational number y such that
++ \spad{y = x (mod p^n)}.

continuedFraction : % -> CF RN
++ \spad{continuedFraction(x)} converts the p-adic rational number x
++ to a continued fraction.

removeZeroes : % -> %
++ \spad{removeZeroes(x)} removes leading zeroes from the
++ representation of the p-adic rational \spad{x}.
++ A p-adic rational is represented by (1) an exponent and
++ (2) a p-adic integer which may have leading zero digits.
++ When the p-adic integer has a leading zero digit, a 'leading zero'
++ is removed from the p-adic rational as follows:
++ the number is rewritten by increasing the exponent by 1 and
++ dividing the p-adic integer by p.
++ Note: \spad{removeZeroes(f)} removes all leading zeroes from f.

removeZeroes : (I,%) -> %
++ \spad{removeZeroes(n,x)} removes up to n leading zeroes from
++ the p-adic rational \spad{x}.

=====

PartialFraction examples

=====

A partial fraction is a decomposition of a quotient into a sum of quotients where the denominators of the summands are powers of primes. Most people first encounter partial fractions when they are learning integral calculus. For a technical discussion of partial fractions, see, for example, Lang's Algebra. For example, the rational number $1/6$ is decomposed into $1/2 - 1/3$. You can compute partial fractions of quotients of objects from domains belonging to the category `EuclideanDomain`. For example, `Integer`, `Complex Integer`, and `UnivariatePolynomial(x, Fraction Integer)` all belong to `EuclideanDomain`. In the examples following, we demonstrate how to decompose quotients of each of these kinds of object into partial fractions.

It is necessary that we know how to factor the denominator when we want to compute a partial fraction. Although the interpreter can often do this automatically, it may be necessary for you to include a call to `factor`. In these examples, it is not necessary to factor the denominators explicitly.

The main operation for computing partial fractions is called `partialFraction` and we use this to compute a decomposition of $1/10!$. The first argument to `partialFraction` is the numerator of the quotient and the second argument is the factored denominator.

```
partialFraction(1,factorial 10)
```

$$\frac{159}{2^8} - \frac{23}{3^4} + \frac{12}{5^2} - \frac{1}{7}$$

Type: PartialFraction Integer

Since the denominators are powers of primes, it may be possible to expand the numerators further with respect to those primes. Use the operation `padicFraction` to do this.

```
f := padicFraction(%)
```

$$\frac{1}{2} + \frac{1}{2^4} + \frac{1}{2^5} + \frac{1}{2^6} + \frac{1}{2^7} + \frac{1}{2^8} - \frac{2}{3^2} - \frac{1}{3^3} - \frac{2}{3^4} - \frac{2}{3^5} - \frac{2}{3^7} + \frac{1}{5^2}$$

Type: PartialFraction Integer

The operation `compactFraction` returns an expanded fraction into the usual form. The compacted version is used internally for computational efficiency.

```
compactFraction(f)
  159   23   12   1
  --- - -- - -- + -
    8    4    2    7
   2    3    5
```

Type: PartialFraction Integer

You can add, subtract, multiply and divide partial fractions. In addition, you can extract the parts of the decomposition. `numberOfFractionalTerms` computes the number of terms in the fractional part. This does not include the whole part of the fraction, which you get by calling `wholePart`. In this example, the whole part is just 0.

```
numberOfFractionalTerms(f)
12
```

Type: PositiveInteger

The operation `nthFractionalTerm` returns the individual terms in the decomposition. Notice that the object returned is a partial fraction itself. `firstNumerator` and `firstDenominator` extract the numerator and denominator of the first term of the fraction.

```
nthFractionalTerm(f,3)
  1
  --
  5
  2
```

Type: PartialFraction Integer

Given two gaussian integers, you can decompose their quotient into a partial fraction.

```
partialFraction(1, -13 + 14 * %i)
      1      4
  - ---- + ----
  1 + 2%i  3 + 8%i
```

Type: PartialFraction Complex Integer

To convert back to a quotient, simply use a conversion.

```
% :: Fraction Complex Integer
      %i
  - ----
  14 + 13%i
```

Type: Fraction Complex Integer

To conclude this section, we compute the decomposition of

$$\frac{1}{(x+1)(x+2)(x+3)(x+4)}$$

The polynomials in this object have type
UnivariatePolynomial(x, Fraction Integer).

We use the primeFactor operation to create the denominator in factored form directly.

```
u : FR UP(x, FRAC INT) := reduce(*,[primeFactor(x+i,i) for i in 1..4])
      2      3      4
(x + 1)(x + 2)(x + 3)(x + 4)
Type: Factored UnivariatePolynomial(x,Fraction Integer)
```

These are the compact and expanded partial fractions for the quotient.

```
partialFraction(1,u)
      1      1      7      17 2      139  607 3      10115 2      391      44179
---- - x + -- - -- x - 12x - ---- - -- x + ---- x + -- x + ----
648  4      16      8      8      324      432      4      324
----- + ----- + ----- + -----
x + 1      2      3      4
(x + 2)      (x + 3)      (x + 4)
Type: PartialFraction UnivariatePolynomial(x,Fraction Integer)
```

```
padicFraction %
      1      1      1      17      3      1      607      403

— domain PFR PartialFraction —

```

)abbrev domain PFR PartialFraction
++ Author: Robert S. Sutor
++ Date Created: 1986
++ Change History: 05/20/91 BMT Converted to the new library
++ Description:
++ The domain \spadtype{PartialFraction} implements partial fractions
++ over a euclidean domain \spad{R}. This requirement on the
++ argument domain allows us to normalize the fractions. Of
++ particular interest are the 2 forms for these fractions. The
++ 'compact' form has only one fractional term per prime in the
++ denominator, while the 'p-adic' form expands each numerator
  
```

```

++ p-adically via the prime p in the denominator. For computational
++ efficiency, the compact form is used, though the p-adic form may
++ be gotten by calling the function padicFraction}. For a
++ general euclidean domain, it is not known how to factor the
++ denominator. Thus the function partialFraction takes as its
++ second argument an element of \spadtype{Factored(R)}.

PartialFraction(R) : SIG == CODE where
  R : EuclideanDomain

FRR ==> Factored R
SUPR ==> SparseUnivariatePolynomial R

SIG ==> Join(Field, Algebra R) with

coerce : % -> Fraction R
++ coerce(p) sums up the components of the partial fraction and
++ returns a single fraction.
++
++X a:=(13/74)::PFR(INT)
++X a::FRAC(INT)

coerce : Fraction FRR -> %
++ coerce(f) takes a fraction with numerator and denominator in
++ factored form and creates a partial fraction. It is
++ necessary for the parts to be factored because it is not
++ known in general how to factor elements of \spad{R} and
++ this is needed to decompose into partial fractions.
++
++X (13/74)::PFR(INT)

compactFraction : % -> %
++ compactFraction(p) normalizes the partial fraction \spad{p}
++ to the compact representation. In this form, the partial
++ fraction has only one fractional term per prime in the
++ denominator.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X compactFraction(b)

firstDenom : % -> FRR
++ firstDenom(p) extracts the denominator of the first fractional
++ term. This returns 1 if there is no fractional part (use
++ wholePart from PartialFraction to get the whole part).
++
++X a:=partialFraction(1,factorial 10)
++X firstDenom(a)

firstNumer : % -> R

```

```

++ firstNumer(p) extracts the numerator of the first fractional
++ term. This returns 0 if there is no fractional part (use
++ wholePart from PartialFraction to get the whole part).
++
++X a:=partialFraction(1,factorial 10)
++X firstNumer(a)

nthFractionalTerm : (%,Integer) -> %
++ nthFractionalTerm(p,n) extracts the nth fractional term from
++ the partial fraction \spad{p}. This returns 0 if the index
++ \spad{n} is out of range.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X nthFractionalTerm(b,3)

numberOfFractionalTerms : % -> Integer
++ numberOfFractionalTerms(p) computes the number of fractional
++ terms in \spad{p}. This returns 0 if there is no fractional
++ part.
++
++X a:=partialFraction(1,factorial 10)
++X b:=padicFraction(a)
++X numberOfFractionalTerms(b)

padicallyExpand : (R,R) -> SUPR
++ padicallyExpand(p,x) is a utility function that expands
++ the second argument \spad{x} ‘p-adically’ in
++ the first.

padicFraction : % -> %
++ padicFraction(q) expands the fraction p-adically in the primes
++ \spad{p} in the denominator of \spad{q}. For example,
++ \spad{padicFraction(3/(2**2)) = 1/2 + 1/(2**2)}.
++ Use compactFraction from PartialFraction to
++ return to compact form.
++
++X a:=partialFraction(1,factorial 10)
++X padicFraction(a)

partialFraction : (R, FRR) -> %
++ partialFraction(numer,denom) is the main function for
++ constructing partial fractions. The second argument is the
++ denominator and should be factored.
++
++X partialFraction(1,factorial 10)

wholePart : % -> R
++ wholePart(p) extracts the whole part of the partial fraction
++ \spad{p}.

```

```

++
++X a:=(74/13)::PFR(INT)
++X wholePart(a)

```

++ Description:
++ Domain for partitions of positive integers
++ Partition is an OrderedCancellationAbelianMonoid which is used
++ as the basis for symmetric polynomial representation of the
++ sums of powers in SymmetricPolynomial. Thus, \spad{(5 2 2 1)} will
++ represent \spad{s5 * s2**2 * s1}.

Partition() : SIG == CODE where

L ==> List
I ==> Integer
OUT ==> OutputForm
NNI ==> NonNegativeInteger
UN ==> Union(%, "failed")

SIG ==> Join(OrderedCancellationAbelianMonoid,
              ConvertibleTo List Integer) with

partition : L I -> %
++ partition(li) converts a list of integers li to a partition

powers : L I -> L L I
++ powers(li) returns a list of 2-element lists. For each 2-element
++ list, the first element is an entry of li and the second
++ element is the multiplicity with which the first element
++ occurs in li. There is a 2-element list for each value
++ occurring in l.

pdct : % -> I
++ \spad{pdct(a1**n1 a2**n2 ...)} returns
++ \spad{n1! * a1**n1 * n2! * a2**n2 * ...}.
++ This function is used in the package \spadtype{CycleIndicators}.

conjugate : % -> %
++ conjugate(p) returns the conjugate partition of a partition p

coerce : % -> List Integer
++ coerce(p) coerces a partition into a list of integers

CODE ==> add

)abbrev domain PATTERN Pattern
++ Author: Manuel Bronstein
++ Date Created: 10 Nov 1988
++ Date Last Updated: 20 June 1991
++ Description:
++ Patterns for use by the pattern matcher.
-- Not exposed.
-- Patterns are optimized for quick answers to structural questions.

Pattern(R) : SIG == CODE where
  R : SetCategory

  B ==> Boolean
  SI ==> SingleInteger
  Z ==> Integer
  SY ==> Symbol
  O ==> OutputForm
  BOP ==> BasicOperator
  QOT ==> Record(num:%, den:%)
  REC ==> Record(val:%, exponent:NonNegativeInteger)
  RSY ==> Record(tag:SI, val: SY, pred:List Any, bad:List Any)
  KER ==> Record(tag:SI, op:BOP, arg:List %)
  PAT ==> Union(ret:R, ker: KER, exp:REC, qot: QOT, sym:RSY)
  -- the following MUST be the name of the formal exponentiation operator
  POWER ==> "%power"::Symbol
  -- the 4 SYM_ constants must be disting powers of 2 (bitwise arithmetic)
  SYM_GENERIC ==> 1::SI
  SYM_MULTIPLE ==> 2::SI
  SYM_OPTIONAL ==> 4::SI
  PAT_PLUS ==> 1::SI
  PAT_TIMES ==> 2::SI
  PAT_LIST ==> 3::SI
  PAT_ZERO ==> 4::SI
  PAT_ONE ==> 5::SI
  PAT_EXPT ==> 6::SI

  SIG ==> Join(SetCategory, RetractableTo R, RetractableTo SY) with

```

```

0 : constant -> %
  ++ \spad{0} is constant

1 : constant -> %
  ++ \spad{1} is constant

isPlus : % -> Union(List %, "failed")
  ++ isPlus(p) returns \spad{[a1,...,an]} if \spad{n > 1}
  ++ and \spad{p = a1 + ... + an},
  ++ and "failed" otherwise.

isTimes : % -> Union(List %, "failed")
  ++ isTimes(p) returns \spad{[a1,...,an]} if \spad{n > 1} and
  ++ \spad{p = a1 * ... * an}, and
  ++ "failed" otherwise.

isOp : (%, BOP) -> Union(List %, "failed")
  ++ isOp(p, op) returns \spad{[a1,...,an]} if \spad{p = op(a1,...,an)},
  ++ and "failed" otherwise.

isOp : % -> Union(Record(op:BOP, arg:List %), "failed")
  ++ isOp(p) returns \spad{[op, [a1,...,an]]} if
  ++ \spad{p = op(a1,...,an)}, and
  ++ "failed" otherwise;

isExpt : % -> Union(REC, "failed")
  ++ isExpt(p) returns \spad{[q, n]} if \spad{n > 0} and \spad{p = q ** n},
  ++ and "failed" otherwise.

isQuotient : % -> Union(QOT, "failed")
  ++ isQuotient(p) returns \spad{[a, b]} if \spad{p = a / b}, and
  ++ "failed" otherwise.

isList : % -> Union(List %, "failed")
  ++ isList(p) returns \spad{[a1,...,an]} if \spad{p = [a1,...,an]},
  ++ "failed" otherwise;

isPower : % -> Union(Record(val:%, exponent:%), "failed")
  ++ isPower(p) returns \spad{[a, b]} if \spad{p = a ** b}, and
  ++ "failed" otherwise.

elt : (BOP, List %) -> %
  ++ \spad{elt(op, [a1,...,an])} returns \spad{op(a1,...,an)}.

"+" : (%, %) -> %
  ++ \spad{a + b} returns the pattern \spad{a + b}.

"*" : (%, %) -> %
  ++ \spad{a * b} returns the pattern \spad{a * b}.

```

```

"*)" : (% , NonNegativeInteger) -> %
  ++ \spad{a ** n} returns the pattern \spad{a ** n}.

"*)" : (% , %) -> %
  ++ \spad{a ** b} returns the pattern \spad{a ** b}.

"/" : (% , %) -> %
  ++ \spad{a / b} returns the pattern \spad{a / b}.

depth : % -> NonNegativeInteger
  ++ depth(p) returns the nesting level of p.

convert : List % -> %
  ++ \spad{convert([a1,...,an])} returns the pattern \spad{[a1,...,an]}.

copy : % -> %
  ++ copy(p) returns a recursive copy of p.

inR? : % -> B
  ++ inR?(p) tests if p is an atom (an element of R).

quoted? : % -> B
  ++ quoted?(p) tests if p is of the form 's for a symbol s.

symbol? : % -> B
  ++ symbol?(p) tests if p is a symbol.

constant? : % -> B
  ++ constant?(p) tests if p contains no matching variables.

generic? : % -> B
  ++ generic?(p) tests if p is a single matching variable.

multiple? : % -> B
  ++ multiple?(p) tests if p is a single matching variable
  ++ allowing list matching or multiple term matching in a
  ++ sum or product.

optional? : % -> B
  ++ optional?(p) tests if p is a single matching variable
  ++ which can match an identity.

hasPredicate? : % -> B
  ++ hasPredicate?(p) tests if p has predicates attached to it.

predicates : % -> List Any
  ++ predicates(p) returns \spad{[p1,...,pn]} such that the predicate
  ++ attached to p is p1 and ... and pn.

```

```

setPredicates : (% , List Any) -> %
  ++ \spad{setPredicates(p, [p1,...,pn])} attaches the predicate
  ++ p1 and ... and pn to p.

withPredicates : (% , List Any) -> %
  ++ \spad{withPredicates(p, [p1,...,pn])} makes a copy of p and attaches
  ++ the predicate p1 and ... and pn to the copy, which is
  ++ returned.

patternVariable : (SY, B, B, B) -> %
  ++ patternVariable(x, c?, o?, m?) creates a pattern variable x,
  ++ which is constant if \spad{c? = true}, optional if \spad{o? = true},
  ++ and multiple if \spad{m? = true}.

setTopPredicate : (% , List SY, Any) -> %
  ++ \spad{setTopPredicate(x, [a1,...,an], f)} returns x with
  ++ the top-level predicate set to \spad{f(a1,...,an)}.

topPredicate : % -> Record(var:List SY, pred:Any)
  ++ topPredicate(x) returns \spad{[[a1,...,an], f]} where the top-level
  ++ predicate of x is \spad{f(a1,...,an)}.
  ++ Note: n is 0 if x has no top-level
  ++ predicate.

hasTopPredicate? : % -> B
  ++ hasTopPredicate?(p) tests if p has a top-level predicate.

resetBadValues : % -> %
  ++ resetBadValues(p) initializes the list of "bad values" for p
  ++ to \spad{[]}.
  ++ Note: p is not allowed to match any of its "bad values".

addBadValue : (% , Any) -> %
  ++ addBadValue(p, v) adds v to the list of "bad values" for p.
  ++ Note: p is not allowed to match any of its "bad values".

getBadValues : % -> List Any
  ++ getBadValues(p) returns the list of "bad values" for p.
  ++ Note: p is not allowed to match any of its "bad values".

variables : % -> List %
  ++ variables(p) returns the list of matching variables
  ++ appearing in p.

optpair : List % -> Union(List %, "failed")
  ++ optpair(l) returns l has the form \spad{[a, b]} and
  ++ a is optional, and
  ++ "failed" otherwise;

=====
Permutation Examples
=====

Permutation(S) implements the group of all bijections on a set S, which move only a finite number of points. A permutation is considered as a map from S into S. In particular, multiplication is defined as composition of maps:

$\text{pi1} * \text{pi2} = \text{pi1} \circ \text{pi2}.$

We represent a permutation as two lists of equal length representing preimages and images of moved points., fixed points do not occur in either of these lists. This enables us to compute the set of fixed points and the set of moved points easily.

```

p := coercePreimagesImages([[1,2,3],[1,2,3]])
1

```

```

Type: Permutation PositiveInteger

movedPoints p
  {}
Type: Set PositiveInteger

even? p
  true
Type: Boolean

p := coercePreimagesImages([[0,1,2,3],[3,0,2,1]])$PERM ZMOD 4
  (1 0 3)
Type: Permutation IntegerMod 4

fixedPoints p
  {2}
Type: Set IntegerMod 4

q := coercePreimagesImages([[0,1,2,3],[1,0]])$PERM ZMOD 4
  (1 0)
Type: Permutation IntegerMod 4

fixedPoints(p*q)
  {2,0}
Type: Set IntegerMod 4

even?(p*q)
  false
Type: Boolean
