1 Numerical Analysis **1**

2 The Quality of Computed Solutions by Sven Hammarling **3**
2.1 Introduction . . . 3
2.2 Floating Point Numbers and IEEE Arithmetic . . . 4
2.2.1 Example 2.1 (Floating point numbers) . . . 4
2.3 Why Worry about Computed Solutions? . . . 6
2.3.1 Example 3.1 (Cancellation) . . . 6
2.3.2 Example 3.2 (Sample variance [High02],Section 1.9) . . . 7
2.3.3 Example 3.3 (Hypotenuse) . . . 8
2.3.4 Example 3.4 (Modulus of a complex number) . . . 9
2.3.5 Example 3.5 (Sample mean)[High98] . . . 10
2.4 Condition, Stability and Error Analysis . . . 11
2.4.1 Condition . . . 11
2.4.2 Stability . . . 18
2.4.3 Error Analysis . . . 23
2.5 Floating Point Error Analysis . . . 27
2.5.1 Example 5.1 (Floating point numbers) . . . 27
2.5.2 Example 5.2 (Product of values) . . . 28
2.5.3 Example 5.3 (Sum of values) . . . 29
2.5.4 Example 5.4 (Difference of two squares) . . . 29
2.5.5 Example 5.5 (The need for pivoting) . . . 31
2.6 Posing the Mathematical Problem . . . 34
2.7 Error Bounds and Software . . . 34
2.8 Other Approaches . . . 38
2.8.1 Example 8.1 (Cancellation and interval arithmetic) . . . 39
2.9 Summary . . . 39

3 Chapter Overview **41**

4 Optimizations **45**

5 Algebra Cover Code **47**
5.1 package BLAS1 BlasLevelOne . . . 47
5.1.1 Axiom Package unit tests . . . 47
5.1.2 Axiom help page . . . 81
5.1.3 BlasLevelOne (BLAS1 Spad code) . . . 82
5.2 lsame . . . 89
5.2.1 fortran code . . . 89
5.2.2 lisp code . . . 91
5.3 xerbla . . . 92
5.3.1 fortran code . . . 92
5.3.2 lisp code . . . 93

6 BLAS Level 1 Real Vector Operations **95**
6.1 sasum - the sum of the absolute values . . . 95
6.1.1 Axiom unit tests . . . 95
6.1.2 Axiom help page . . . 95
6.1.3 fortran code . . . 96
6.1.4 lisp code . . . 97
6.2 saxpy - constant times a vector plus a vector . . . 99
6.2.1 Axiom unit tests . . . 99
6.2.2 Axiom help page . . . 99
6.2.3 fortran code . . . 100
6.2.4 lisp code . . . 101
6.3 scabs1 - abs(real(z))+abs(imag(z)) of a complex number . . . 103
6.3.1 Axiom unit tests . . . 103
6.3.2 Axiom help page . . . 104
6.3.3 fortran code . . . 104
6.3.4 lisp code . . . 105
6.4 scasum - abs(real(z))+abs(imag(z)) of a complex vector . . . 105
6.4.1 Axiom unit tests . . . 105
6.4.2 Axiom help page . . . 106
6.4.3 fortran code . . . 106
6.4.4 lisp code . . . 107
6.5 scnrm2 - Euclidean norm of a vector . . . 109
6.5.1 Axiom unit tests . . . 109
6.5.2 Axiom help page . . . 109
6.5.3 fortran code . . . 110
6.5.4 lisp code . . . 111
6.6 scopy - copy a vector x to a vector y . . . 112
6.6.1 Axiom unit tests . . . 112
6.6.2 Axiom help page . . . 113
6.6.3 fortran code . . . 113
6.6.4 lisp code . . . 115
6.7 sdot - compute the dot product of two vectors . . . 117
6.7.1 Axiom unit tests . . . 117
6.7.2 Axiom help page . . . 117

6.7.3 fortran code . . . 118
6.7.4 lisp code . . . 119
6.8 sdsdot - compute the inner product of two vectors . . . 121
6.8.1 Axiom unit tests . . . 121
6.8.2 Axiom help page . . . 121
6.8.3 fortran code . . . 122
6.8.4 lisp code . . . 124
6.9 snrm2 - Euclidean norm of a vector $\sqrt{x'x}$ . . . 126
6.9.1 Axiom unit tests . . . 126
6.9.2 Axiom help page . . . 126
6.9.3 fortran code . . . 127
6.9.4 lisp code . . . 128
6.10 srot - applies a plane rotation . . . 129
6.10.1 Axiom unit tests . . . 129
6.10.2 Axiom help page . . . 130
6.10.3 fortran code . . . 130
6.10.4 lisp code . . . 131
6.11 srotg - construct givens plane rotation . . . 133
6.11.1 Axiom unit tests . . . 133
6.11.2 Axiom help page . . . 133
6.11.3 fortran code . . . 134
6.11.4 lisp code . . . 135
6.12 srotm - apply a modified givens transformation . . . 135
6.12.1 Axiom unit tests . . . 135
6.12.2 Axiom help page . . . 136
6.12.3 fortran code . . . 137
6.12.4 lisp code . . . 140
6.13 srotmg - apply a modified givens transformation . . . 143
6.13.1 Axiom unit tests . . . 143
6.13.2 Axiom help page . . . 143
6.13.3 fortran code . . . 144
6.13.4 lisp code . . . 148
6.14 sscal - scales a vector by a constant . . . 150
6.14.1 Axiom unit tests . . . 150
6.14.2 Axiom help page . . . 150
6.14.3 fortran code . . . 151
6.14.4 lisp code . . . 152
6.15 sswap - interchange two vectors . . . 154
6.15.1 Axiom unit tests . . . 154
6.15.2 Axiom help page . . . 154
6.15.3 fortran code . . . 155
6.15.4 lisp code . . . 156

7 BLAS Level 1 Double Vector Operations **159**
7.1 dasum - sum of the absolute values . . . 159
7.1.1 Axiom unit tests . . . 159
7.1.2 Axiom help page . . . 164
7.1.3 fortran code . . . 168
7.1.4 fortran unit test . . . 169
7.1.5 lisp code . . . 172
7.2 daxpy - constant time vector plus a vector . . . 172
7.2.1 Axiom unit tests . . . 172
7.2.2 Axiom help page . . . 176
7.2.3 fortran code . . . 180
7.2.4 fortran unit test . . . 181
7.2.5 lisp code . . . 184
7.3 dcabs1 - abs(real(z))+abs(imag(z)) . . . 185
7.3.1 Axiom unit tests . . . 185
7.3.2 Axiom help page . . . 187
7.3.3 fortran code . . . 188
7.3.4 fortran unit test . . . 189
7.3.5 lisp code . . . 190
7.4 dcopy - copy a vector x to a vector y . . . 190
7.4.1 Axiom unit tests . . . 190
7.4.2 Axiom help page . . . 194
7.4.3 fortran code . . . 196
7.4.4 fortran unit test . . . 198
7.4.5 lisp code . . . 200
7.5 ddot - dot product of two vectors . . . 202
7.5.1 Axiom unit tests . . . 202
7.5.2 Axiom help page . . . 203
7.5.3 fortran code . . . 205
7.5.4 fortran unit test . . . 207
7.5.5 lisp code . . . 209
7.6 dnrm2 - Euclidean norm of a vector . . . 210
7.6.1 Axiom unit tests . . . 210
7.6.2 Axiom help page . . . 211
7.6.3 fortran code . . . 212
7.6.4 fortran unit test . . . 214
7.6.5 lisp code . . . 215
7.7 drot - applies a plane rotation . . . 216
7.7.1 Axiom unit tests . . . 216
7.7.2 Axiom help page . . . 221
7.7.3 fortran code . . . 223
7.7.4 fortran unit test . . . 225
7.7.5 lisp code . . . 230
7.8 drotg - constructs givens plane rotation . . . 233
7.8.1 Axiom unit tests . . . 233
7.8.2 Axiom help page . . . 235

7.8.3 fortran code . . . 239
7.8.4 fortran unit test . . . 240
7.8.5 lisp code . . . 244
7.9 drotm - Apply the modified givens transformation to DX^T . . . 246
7.9.1 Axiom unit tests . . . 246
7.9.2 Axiom help page . . . 246
7.9.3 fortran code . . . 248
7.9.4 lisp code . . . 250
7.10 drotmg - Construct the modified givens transformation matrix . . . 253
7.10.1 Axiom unit tests . . . 253
7.10.2 Axiom help page . . . 253
7.10.3 fortran code . . . 255
7.10.4 lisp code . . . 258
7.11 dscal - scale a vector by a constant . . . 260
7.11.1 Axiom unit tests . . . 260
7.11.2 Axiom help page . . . 262
7.11.3 fortran code . . . 264
7.11.4 fortran unit test . . . 265
7.11.5 lisp code . . . 267
7.12 dsdot - compute the inner product of two vectors . . . 268
7.12.1 Axiom unit tests . . . 268
7.12.2 Axiom help page . . . 269
7.12.3 fortran code . . . 270
7.12.4 lisp code . . . 271
7.13 dswap - interchanges two vectors . . . 272
7.13.1 Axiom unit tests . . . 272
7.13.2 Axiom help page . . . 274
7.13.3 fortran code . . . 276
7.13.4 fortran unit test . . . 278
7.13.5 lisp code . . . 280
7.14 dtrsv - solve $Ax = b$ or $A^T x = b$ . . . 281
7.14.1 Axiom unit tests . . . 281
7.14.2 Axiom help page . . . 281
7.14.3 fortran code . . . 283
7.14.4 lisp code . . . 287
7.15 dzasum - sum of the dcabs1 of a complex vector . . . 295
7.15.1 Axiom unit tests . . . 295
7.15.2 Axiom help page . . . 296
7.15.3 fortran code . . . 297
7.15.4 fortran unit test . . . 298
7.15.5 lisp code . . . 300
7.16 dznrm2 - Euclidean norm of a vector = $\sqrt{x^H * x}$ . . . 301
7.16.1 Axiom unit tests . . . 301
7.16.2 Axiom help page . . . 302
7.16.3 fortran code . . . 304
7.16.4 fortran unit test . . . 306

7.16.5 lisp code . . . 307
7.17 icamax - maximum index function . . . 309
7.17.1 Axiom unit tests . . . 309
7.17.2 Axiom help page . . . 310
7.17.3 fortran code . . . 312
7.17.4 fortran unit test . . . 314
7.17.5 lisp code . . . 316
7.18 idamax - index of element having max. absolute value . . . 317
7.18.1 Axiom unit tests . . . 317
7.18.2 Axiom help page . . . 319
7.18.3 fortran code . . . 322
7.18.4 fortran unit test . . . 324
7.18.5 lisp code . . . 325
7.19 isamax - index of element having max. absolute value . . . 326
7.19.1 Axiom unit tests . . . 326
7.19.2 Axiom help page . . . 328
7.19.3 fortran code . . . 331
7.19.4 fortran unit test . . . 332
7.19.5 lisp code . . . 334
7.20 izamax . . . 335
7.20.1 Axiom unit tests . . . 335
7.20.2 Axiom help page . . . 336
7.20.3 fortran code . . . 338
7.20.4 fortran unit test . . . 339
7.20.5 lisp code . . . 341

8 BLAS Level 1 Complex Vector Operations 345
8.1 caxpy - constant times a vector plus a vector . . . 345
8.1.1 Axiom unit tests . . . 345
8.1.2 Axiom help page . . . 345
8.1.3 fortran code . . . 346
8.1.4 lisp code . . . 347
8.2 ccopy - copies a vector x to a vector y . . . 349
8.2.1 Axiom unit tests . . . 349
8.2.2 Axiom help page . . . 349
8.2.3 fortran code . . . 350
8.2.4 lisp code . . . 351
8.3 cdotc - dot product of two complex vectors $X^H Y$ . . . 352
8.3.1 Axiom unit tests . . . 352
8.3.2 Axiom help page . . . 352
8.3.3 fortran code . . . 353
8.3.4 lisp code . . . 354
8.4 cdotu - dot product of two complex vectors $X^T Y$ . . . 355
8.4.1 Axiom unit tests . . . 355
8.4.2 Axiom help page . . . 355
8.4.3 fortran code . . . 356

8.4.4 lisp code . . . 357
8.5 crotg - determines a complex Givens rotation . . . 358
8.5.1 Axiom unit tests . . . 358
8.5.2 Axiom help page . . . 359
8.5.3 fortran code . . . 359
8.5.4 lisp code . . . 360
8.6 cscal - scales a vector by a constant . . . 361
8.6.1 Axiom unit tests . . . 361
8.6.2 Axiom help page . . . 362
8.6.3 fortran code . . . 362
8.6.4 lisp code . . . 363
8.7 csrot - appies a plane rotation . . . 364
8.7.1 Axiom unit tests . . . 364
8.7.2 Axiom help page . . . 364
8.7.3 fortran code . . . 366
8.7.4 lisp code . . . 367
8.8 csscal - scales a complex vector by a real constant . . . 368
8.8.1 Axiom unit tests . . . 368
8.8.2 Axiom help page . . . 369
8.8.3 fortran code . . . 369
8.8.4 lisp code . . . 370
8.9 cswap - interchanges two vectors . . . 371
8.9.1 Axiom unit tests . . . 371
8.9.2 Axiom help page . . . 372
8.9.3 fortran code . . . 372
8.9.4 lisp code . . . 374

9 BLAS Level 1 Complex16 Vector Operations 377
9.1 zaxpy - constant times a vector plus a vector . . . 377
9.1.1 Axiom unit tests . . . 377
9.1.2 Axiom help page . . . 381
9.1.3 fortran code . . . 384
9.1.4 fortran unit test . . . 385
9.1.5 lisp code . . . 391
9.2 zcopy - copies a vector x to a vector y . . . 394
9.2.1 Axiom unit tests . . . 394
9.2.2 Axiom help page . . . 394
9.2.3 fortran code . . . 395
9.2.4 lisp code . . . 396
9.3 zdotc - dot product of two complex vectors $X^H Y$ . . . 397
9.3.1 Axiom unit tests . . . 397
9.3.2 Axiom help page . . . 398
9.3.3 fortran code . . . 399
9.3.4 lisp code . . . 401
9.4 zdotu - forms the dot product of two complex vectors $X^T Y$ . . . 402
9.4.1 Axiom unit tests . . . 402

9.4.2 Axiom help page . . . 402
9.4.3 fortran code . . . 404
9.4.4 lisp code . . . 405
9.5 zdrot - applies a plane rotation . . . 406
9.5.1 Axiom unit tests . . . 406
9.5.2 Axiom help page . . . 407
9.5.3 fortran code . . . 408
9.5.4 lisp code . . . 409
9.6 zdscal - scales a vector by a constant . . . 411
9.6.1 Axiom unit tests . . . 411
9.6.2 Axiom help page . . . 411
9.6.3 fortran code . . . 412
9.6.4 lisp code . . . 413

New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Chapter 1

Numerical Analysis

We can describe each number as x^* which has a machine-representable form which differs from the number x it is intended to represent. Quoting Householder [Hous81] we get:

$$x^* = \pm(x_1\beta^{-1} + x_2\beta^{-2} + \cdots + x_\lambda\beta^\lambda)\beta^\sigma$$

where β is the base, usually 2 or 10, λ is a positive integer, and σ is any integer, possibly zero. It may be that λ is fixed throughout the course of the computation, or it may vary, but in any case it is limited by practical considerations. Such a number will be called a representation. It may be that x^* is obtained by "rounding off" a number whose true value is x (for example, $x = 1/3$, $x^* = 0.33$), or that x^* is the result of measuring physically a quantity whose true value is x, or that x^* is the result of a computation intended to give an approximation to the quantity x.

Suppose one is interested in performing an operations ω upon a pair of numbers x and y. That is to say, $x\omega y$ may represent a product of x and y, a quotient of x by y, the yth power of x, ... In the numerical computation, however, one has only x^* and y^* upon which to operate, not x and y (or at least these are the quantitites upon which one does, in fact operate). Not only this, but often one does not even perform the strict operation ω, but rather a pseudo operation ω^*, which yields a rounded-off product, quotient, power, etc. Hence, instead of obtaining the desired result $x\omega y$, one obtains a result $x^*\omega^*y^*$.

The error in the result is therefore

$$x\omega y - x^*\omega^*y^* = (x\omega y - x^*\omega y^*) + (x^*\omega y^* - x^*\omega^*y^*)$$

Since x^* and y^* are numbers, the operation ω can be applied to them, and $x^*\omega y^*$ is well defined, except for special cases as when ω represents division and $y^* = 0$. But the expression in the first parenthesees on the right represents propagated error, and that in the second parentheses represents generated error, or round-off. Hence the total error in the result is the sum of the error propagated by the operation and that generated by the operation.

Householder notes that, given two operations ω and ϕ, it may be true that the operations are associative, e.g:

$$(x^*\omega y^*)\phi z^* = x^*\omega(y^*\phi z^*)$$

but if we expand these in terms of the above definitions of propogation and generation error we get two different expressions:

$$\begin{aligned}(x^*\omega y^*)\phi z^* - (x^*\omega^* y^*)\phi^* z^* &= [(x^*\omega y^*)\phi z^* - (x^*\omega^* y^*)\phi z^*] \\ &+ [(x^*\omega^* y^*)\phi z^* - (x^*\omega^* y^*)\phi^* z^*]\end{aligned}$$

$$\begin{aligned}x^*\omega(y^*\phi z^*) - x^*\omega^*(y^*\phi^* z^*) &= [x^*\omega(y^*\phi z^*) - x^*\omega(y^*\phi^* z^*)] \\ &+ [x^*\omega(y^*\phi^* z^*) - x^*\omega^*(y^*\phi^* z^*)]\end{aligned}$$

These are not always equal which implies that the strictly machine operations are not necessarily commutative.

Householder distinguishes a third class of error (besides propagation and generative) called residual errors. This occurs because some functions are approximated by infinite series. The finite computation of the series forces the truncation of the remaining terms causing these residual errors.

We will try to perform an analysis of each of the routines in this library for the given inputs to try to see the propagation errors and generation errors they introduce. Every effort will be made to minimize these errors. In particular, we will appeal to the machine generated code to see what approximations actually occur.

Chapter 2

The Quality of Computed Solutions by Sven Hammarling

This is quoted with permission from Hammarling[Hamm05]

2.1 Introduction

This report is concerned with the quality of the computed numerical solutions of mathematical problems. For example, suppose we wish to solve the system of linear equations $Ax = b$ using a numerical software package. The package will return a computed solution, say $\tilde{x}$, and we wish to judge whether or not $\tilde{x}$ is a reasonable solution to the equations. Sadly, all too often software packages return poor, or even incorrect, numerical results and give the user no means by which to judge the quality of the numerical results. In 1971, Leslie Fox commented [[Foxx71] 1971, p. 296]

> I have little doubt that about 80 per cent. of all the results printed from the computer are in error to a much greater extent than the user would believe, ...

More than thirty years on that paper is still very relevant and worth reading. Another very readable article is [Fors70].

The quality of computed solutions is concerned with assessing how good a computed solution is in some appropriate measure. Quality software should implement reliable algorithms and should, if possible, provide measures of solution quality.

In this report we give an introduction to ideas that are important in understanding and measuring the quality of computed solutions. In particular we review the ideas of condition, stability and error analysis, and their realisation in numerical software. We take as the principal example LAPACK [Ande99], a package for the solution of dense and banded linear algebra problems, but also draw on examples from the NAG Library [NAGa05] and

elsewhere . The aim is not to show how to perform an error analysis, but to indicate why an understanding of the ideas is important in judging the quality of numerical solutions, and to encourage the use of software that returns indicators of the quality of the results. We give simple examples to illustrate some of the ideas that are important when designing reliable numerical software.

Computing machines use floating point arithmetic for their computation, and so we start with an introduction to floating point numbers.

2.2 Floating Point Numbers and IEEE Arithmetic

Floating point numbers are a subset of the real numbers that can be conveniently represented in the finite word length of a computer, without unduly restricting the range of numbers represented. For example, the ANSI/IEEE standard for binary floating point arithmetic [IEEE85] uses 64 bits to represent double precision numbers in the approximate range $10^{\pm 308}$. A floating point number, x, can be represented in terms of four integers as

$$x = \pm m \times b^{e-t}$$

where b is the *base* or *radix*, t is the *precision*, e is the *exponent* with an *exponent range* of $[e_{min}, e_{max}]$ and m is the *mantissa* or *significand*, satisfying $0 \leq m \leq b^t - 1$. If $x \neq 0$ and $m \geq b^{t-1}$ then x is said to be *normalized*. An alternative, equivalent representation of x is

$$\begin{aligned} x &= \pm 0.d_1 d_2 \ldots d_t \times b^e \\ &= \pm \left(\tfrac{d_1}{b} + \tfrac{d_2}{b^2} + \cdots + \tfrac{d_t}{b^t} \right) \times b^e \end{aligned}$$

where each digit satisfies $0 \leq d_i \leq b - 1$. If $d_1 \neq 0$ then we see that x is normalized. If $d_1 = 0$ and $x \neq 0$ then x is said to be *denormalized*. Denormalized numbers between 0 and the smallest normalized number are called *subnormal*. Note that denormalized numbers do not have the full t digits of precision.

The following example, which is not intended to be realistic, illustrates the model.

2.2.1 Example 2.1 (Floating point numbers)

$$b = 2, \quad t = 2, \quad e_{\min} = -2, \quad e_{\max} = 2$$

All the normalized numbers have $d_1 = 1$ and either $d_2 = 0$ or $d_2 = 1$, that is m is one of the two binary integers $m = 10$ $(= 2)$ or $m = 11$ $(= 3)$. Denormalized numbers have $m = 01$ $(= 1)$. Thus the smallest positive normalized number is $2 \times 2^{e_{\min} - t} = \frac{1}{8}$ and the largest is $3 \times 2^{e_{\max} - t} = 3$. The value $1 \times 2^{e_{\min} - t} = \frac{1}{16}$ is the only positive subnormal number in this system. The complete set of non-negative normalized numbers is

$$0, \frac{1}{8}, \frac{3}{16}, \frac{1}{4}, \frac{3}{8}, \frac{1}{2}, \frac{3}{4}, 1, \frac{3}{2}, 2, 3$$

The set of non-negative floating point numbers is illustrated in Figure 1, where the subnormal number is indicated by a dashed line.

$b = 2,\ t = 2,\ e_{\min} = -2,\ e_{\max} = 2$

Figure 1: Floating Point Number Example

Note that floating point numbers are not equally spaced absolutely, but the relative spacing between numbers is approximately equal. The value

$$u = \frac{1}{2} \times b^{1-t} \tag{1}$$

is called the *unit roundoff*, or the *relative machine precision* and is the furthest distance relative to unity between a real number and the nearest floating point number. In Example 2.1, $u = \frac{1}{4} = 0.25$ and we can see, for example, that the furthest real number from 1.0 is 1.25 and the furthest real number from 2.0 is 2.5. u is fundamental to floating point error analysis.

The value $e_M = 2u$ is called *machine epsilon*.

The ANSI/IEEE standard mentioned above (usually referred to as IEEE arithmetic), which of course has $b = 2$, specifies:

- floating point number formats
- results of the basic floating point operations
- rounding modes
- signed zero, infinity ($\pm\infty$) and not-a-number (NaN)
- floating point exceptions and their handling and
- conversion between formats

Thankfully, nowadays almost all machines use IEEE arithmetic. There is also a generic ANSI/IEEE, base independent, standard [IEEE87]. The formats supported by the ANSI/IEEE binary standard are indicated in Table 1.

Format	Precision	Exponent	Approx Range	Approx Precision
Single	24 bits	8 bits	$10^{\pm 38}$	10^{-8}
Double	53 bits	11 bits	$10^{\pm 308}$	10^{-16}
Extended	$\geq$ 64 bits	$\geq$ 15 bits	$10^{\pm 4932}$	10^{-20}

The default rounding mode for IEEE arithmetic is round to nearest, in which a real number is represented by the nearest floating point number, with rules as to how to handle a tie [[Over01], Chapter 5].

Whilst the ANSI/IEEE standard has been an enormous help in standardizing floating point computation, it should be noted that moving a computation between machines that implement IEEE arithmetic does not guarantee that the computed results will be the same. Variations can occur due to such things as compiler optimization, the use of extended precision registers, and fused multiply-add.

Further discussion of floating point numbers and IEEE arithmetic can be found in [High02] and [Over01].

The value u can be obtained from the LAPACK function SLAMCH, for single precision arithmetic, or DLAMCH for double precision arithmetic by calling the function with the argument CMACH as e, and is also returned by the NAG Fortran Library routine X02AJF[1] It should be noted that on machines that truncate, rather than round, M is returned in place of u, but such machines are now rare. It should also be noted that e in S/DLAMCH represents eps, but this should not be confused with M. The Matlab built in variable eps returns M[Math05], as does the Fortran 95/Fortran 2003 numeric enquiry function epsilon [Metc96, Metc04].

2.3 Why Worry about Computed Solutions?

In this section we consider some simple examples of numerical computation that need care in order to obtain reasonable solutions. For clarity of exposition, most of the examples in this and the following sections are illustrated using decimal floating point (significant figure) arithmetic, with round to nearest.

The first example illustrates the problem of damaging subtraction, usually referred to as *cancellation*.

2.3.1 Example 3.1 (Cancellation)

Using four figure decimal arithmetic, suppose we wish to compute $s = 1.000 + 1.000 \times 10^4 - 1.000 \times 10^4$. *If we compute in the standard way from left to right we obtain*

$$\begin{aligned} s &= 1.000 + 1.000 \times 10^4 - 1.000 \times 10^4 \\ &= (1.000 + 1.000 \times 10^4) - 1.000 \times 10^4 \\ &= 1.000 \times 10^4 - 1.000 \times 10^4 \\ &= 0 \end{aligned}$$

instead of the correct result of 1.0. Although the cancellation (subtraction) was performed exactly, it lost all the information for the solution.

[1] In some ports it actually returns $u + b^{1=2t}$. See the X02 Chapter introduction[NAGb05].

As Example 3.1 illustrates, the cause of the poor result often happens before the cancellation, and the cancellation is just the final nail in the coffin. In Example 3.1, the damage was done in computing $s = 1.000 + 1.000 \times 10^4$, where we lost important information (1.000). It should be said that the subtraction of nearly equal numbers is not always damaging.

Most problems have alternative formulations which are theoretically equivalent, but may computationally yield quite different results. The following example illustrates this in the case of computing sample variances.

2.3.2 Example 3.2 (Sample variance [High02],Section 1.9)

The sample variance of a set of n values $x_1, x_2, \ldots, x_n$ is defined as

$$s_n^2 = \frac{1}{n-1} \sum_{i=1}^{n} (x_i - \overline{x})^2 \tag{2}$$

where $\overline{x}$ is the sample mean of the n values

$$\overline{x} = \frac{1}{n} \sum_{i=1}^{n} x_i$$

An alternative, theoretically equivalent, formula to compute the sample variance which requires only one pass through the data is given by

$$s_n^2 = \frac{1}{n-1} \left(\sum_{i=1}^{n} x_i^2 - \frac{1}{n} \left(\sum_{i=1}^{n} x_i \right)^2 \right) \tag{3}$$

If x^T = (10000 10001 10002) then using 8 figure arithmetic (2) gives $s^2 = 1.0$, the correct answer, but (3) gives $s^2 = 0.0$, with a relative error of 1.0.

(3) can clearly suffer from cancellation, as illustrated in the example. On the other hand, (2) always gives good results unless n is very large [[High02], Problem 1.10]. See also [Chan83] for further discussion of the problem of computing sample variances.

Sadly, it is not unknown for software packages and calculators to implement the algorithm of (3). For example in Excel 2002 from Microsoft Office XP (and in previous versions of Excel also), the function STDEV computes the standard deviation, s, of the data

$$x^T = (10000000010000000011000000002)$$

as $s = 0$. Considering the pervasive use of Excel and the importance of standard deviation and its use in applications, it is disappointing to realise that (3) has been used by these versions of Excel.[2] See [Coxx00] for further information, as well as [Knus98], [Mccu99] and [Mccu02]. The spreadsheet from OpenOffice.org version 1.0.2 produces the same result, but gives no information on the method used in its help system; on the other hand the Gnumeric

[2]The algorithm has at last been replaced in Excel from Office 2003, which now gives the correct answer.

spreadsheet (version 1.0.12) gives the correct result, although again the function description does not describe the method used.[3]

A result that is larger than the largest representable floating point number is said to *overflow*. For example, in double precision IEEE arithmetic for which the approximate range is $10^{\pm 308}$, if $x = 10^{200}$, then x^2 would overflow. Similarly, x^{-2} is said to *underflow* because it is smaller than the smallest non-zero representable floating point number.

As with the unit rounding error or machine epsilon discussed in Section 2, the overflow and underflow thresholds can be obtained from the LAPACK function S/DLAMCH by calling the function with the argument CMACH as o and u respectively; from the NAG Fortran Library routines X02ALF and X02AKF respectively; the Matlab built in variables `realmax` and `realmin`; and from the Fortran 95 numeric enquiry functions `huge` and `tiny`.

Care needs to be taken to avoid unnecessary overflow and damaging underflow. The following example illustrates this care in the case of computing the hypotenuse of the right angled triangle shown in Figure 2.

Figure 2: Hypotenuse of a right angled triangle

2.3.3 Example 3.3 (Hypotenuse)

in Figure 2, if x or y is very large there is a danger of overflow, even if z is representable. Assuming that x and y are non-negative, a safe method of computing z is

$$a = \max(x, y), \;\; b = \min(x, y)$$

$$z = \begin{cases} a\sqrt{1 + \left(\frac{b}{a}\right)^2}, & a > 0 \\ 0 & a = 0 \end{cases}$$

This also avoids z being computed as zero if x^2 and y^2 both underflow. We note that

[3]OpenOffice.org version 2.0 also now gives the correct result

[Stew98], p.139 and p144 actually recommends computing z as

$$z = \begin{cases} s\sqrt{\left(\frac{x}{s}\right)^2 + \left(\frac{y}{s}\right)^2}, \text{where } s = x + y, & x > 0 \\ 0 & s = 0 \end{cases}$$

because this is slightly more accurate on a hexadecimal machine. An interesting alternative for computing Pythagorean sums is given in [Mole83]; see also [Dubr83] and [High05], section 22.9.

We can see that (3) of Example 3.2 also has the potential for overflow and underflow and, as well as implementing this formula rather than a more stable version, Excel does not take the necessary care to avoid underflow and overflow. For example, for the values (1.0E200, 1.0E200), STDEV in Excel 2003 from Microsoft Office 2003 returns the mysterious symbol #NUM!, which signifies a numeric exception, in this case overflow, due to the fact that $(10.0^{200})^2$ overflows in IEEE double precision arithmetic. The correct standard deviation is of course 0. Similarily, for the values (0, 1.0E-200, 2.0E-200), STDEV returns the value 0 rather than the correct value of 1.0E-200. OpenOffice.org version 1.0.2 also returns zero for this data, and overflows on the previous data. Mimicking Excel is not necessarily a good thing![4]

The computation of the modulus of a complex number $x = x_r + ix_i$ requires almost the same computation as that in Example 3.3.

2.3.4 Example 3.4 (Modulus of a complex number)

$$|x| = \sqrt{x_r^2 + x_i^2}$$

$$a = \max(|x_r|, |x_i|),\ b = \min(|x_r|, |x_i|)$$

$$|x| = \begin{cases} a\sqrt{1 + \left(\frac{b}{a}\right)^2} & a > 0 \\ 0 & a = 0 \end{cases}$$

Again this also avoids $|x|$ being computed as zero if x_r^2 and x_i^2 both underflow.

Another example where care is needed in complex arithmetic is complex division

$$\frac{x}{y} = \frac{x_r + ix_i}{y_r + iy_i} = \frac{(x_r + ix_i)(y_r - iy_i)}{y_r^2 + y_i^2}$$

Again, some scaling is required to avoid overflow and underflow. See for example [Smit62], [Stew85] and [Prie04]. Algol 60 procedures for the complex operations of modulus, division and square root are given in [Mart68] and the NAG Library Chapter, A02, for complex arithmetic has routines based upon those Algol procedures, see for example [NAGb05]. A

[4] OpenOffice.org version 2.0 now produces the correct result for the data (1.0E200,1.0E200), but underflows for (0,1.0E-200,2.0E-200)

careful C function is given in the Priest reference above. Occasionally, some aspect of complex floating point arithmetic is incorrectly implemented, see for example [Blac97], Section 7.

Another example, similar to the previous examples, requiring care to avoid overflow and damaging underflow is that of real plane rotations where we need to compute $c = \cos\theta$ and $s = \sin\theta$ such that

$$c = \frac{x}{z},\ s = \frac{y}{z},\ \text{where } z = \sqrt{x^2 + y^2}$$

or alternatively

$$c = \frac{-x}{z},\ s = \frac{-y}{z}$$

Another convenient way to express the two choices is as

$$c = \frac{\pm 1}{\sqrt{1+t^2}},\ s = ct,\ \text{where } t \equiv \tan\theta = \frac{x}{y} \tag{4}$$

If G is the *plane rotation matrix*

$$G = \begin{pmatrix} c & s \\ -s & c \end{pmatrix}$$

then, with the choices of (4),

$$G \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \pm z \\ 0 \end{pmatrix}$$

When used in this way for the introduction of zeros the rotation is generally termed a Givens plane rotation [Give54]; [Golu96]. Givens himself certainly took care in the computation of c and s. To see an extreme case of the detailed consideration necessary to implement a seemingly simple algorithm, but to be efficient, to preserve as much accuracy as possible throughout the range of floating point numbers, and to avoid overflow and damaging underflow see [Bind02], where the computation of the Givens plane rotation is fully discussed.

Sometimes computed solutions are in some sense reasonable, but may not be what the user was expecting. In the next example, the computed solution is close to the exact solution, but does not meet a constraint that the user might have expected the solution to meet.

2.3.5 Example 3.5 (Sample mean)[High98]

Using three figure floating point decimal arithmetic:

$$(5.01 + 5.03)/2 \Rightarrow 10.0/2 \Rightarrow 5.00$$

and we see that the computed value is outside the range of the data, although it is not inaccurate.

Whether or not such a result matters depends upon the application, but is an issue that needs to be considered when implementing numerical algorithms. For instance if

$$y = \cos x$$

then we probably expect the property $|y| \leq 1$ to be preserved computationally, so that a value $|y| > 1$ is never returned. For a monotonic function we may expect monotonicity to be preserved computationally.

In the next section we look at ideas that help our understanding of what constitutes a quality solution.

2.4 Condition, Stability and Error Analysis

2.4.1 Condition

Firstly we look at the condition of a problem. The condition of a problem is concerned with the sensitivity of the problem to perturbations in the data. A problem is ill-conditioned if small changes in the data cause relatively large changes in the solution. Otherwise a problem is well-conditioned. Note that condition is concerned with the sensitivity of the problem, and is independent of the method we use to solve the problem. We now give some examples to illustrate somewhat ill-conditioned problems.

2.4.1.1 Example 4.1 (Cubic equation)

Consider the cubic equation

$$x^3 - 21x^2 + 120x - 100 = 0$$

whose exact roots are $x_1 = 1$, $x_2 = x_3 = 10$. *If we perturb the coefficient of* x^3 *to give*

$$0.99x^3 - 21x^2 + 120x - 100 = 0$$

the roots become $x_1 \approx 1.000$,$x_2 \approx 11.17$, $x_3 \approx 9.041$, *so that the changes in the two roots* x_2 *and* x_3 *are significantly greater than the change in the coefficient. On the other hand, the roots of the perturbed cubic equation*

$$1.01x^3 - 21x^2 + 120x - 100 = 0$$

are $x_1 \approx 1.000$,$x_2, x_3 \approx 9.896 \pm 1.044i$,*and this time the double root has become a complex conjugate pair with a significant imaginary part.*

We can see that the roots x_2 *and* x_3 *are ill-conditionsed. Note that we cannot deduce anything about the condition of* x_1 *just from this data. The three cubic polynomials are plotted in Figure 3.*

Figure 3: Cubic Equation Example

2.4.1.2 Example 4.2 (Eigenvalue problem)

The matrix

$$A = \begin{pmatrix} 10 & 100 & 0 & 0 \\ 0 & 10 & 100 & 0 \\ 0 & 0 & 10 & 100 \\ 0 & 0 & 0 & 10 \end{pmatrix}$$

has eigenvalues $\lambda_1 = \lambda_2 = \lambda_3 = \lambda_4 = 10$, *whereas the slightly perturbed matrix*

$$B = \begin{pmatrix} 10 & 100 & 0 & 0 \\ 0 & 10 & 100 & 0 \\ 0 & 0 & 10 & 100 \\ 10^{-6} & 0 & 0 & 10 \end{pmatrix}$$

has eigenvalues $\lambda_1 = 11, \lambda_2, \lambda_3 = 10 \pm i$, $\lambda_4 = 9$.

2.4.1.3 Example 4.3 (Integral)

$$I = \int_{-10}^{10} (ae^x - be^{-x})\, dx$$

When $a = b = 1$, $I = 0$, *but when* $a = 1$, $b+1.01$, $I \approx -220$. *The function* $f(x) = xe^x - be^{-x}$, *when* $a = b = 1$ *is plotted in Figure 4. Notice that the vertical scale has a scale factor of* 10^4, *so that a small change in function can make a large change in the area under the curve.*

Figure 4: Integral Example

2.4.1.4 Example 4.4 (Linear Equations)

The equations $Ax = b$ *given by*

$$\begin{pmatrix} 99 & 98 \\ 100 & 99 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 197 \\ 199 \end{pmatrix} \tag{5}$$

have the solution $x_1 = x + 2 = 1$, *but the equations*

$$\begin{pmatrix} 98.99 & 98 \\ 100 & 99 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} = \begin{pmatrix} 197 \\ 199 \end{pmatrix}$$

have the solution $x_1 = 100$, $x_2 = -99$. The two straight lines represented by (5) are plotted in Figure 5, but to the granularity of the graph we cannot tell the two lines apart.

Figure 5: Linear Equations Example

To be able to decide whether or not a problem is ill-conditioned it is clearly desirable to have some measure of the condition of a problem. We show two simple cases where we can obtain such a measure, and quote the result for a third example. For the first case we derive the condition number for the evaluation of a function of one variable [[High02], Section 1.6].

Let $y = f(x)$ with f twice differentiable and $f(x) \neq 0$. Also let $\hat{y} = f(x + \epsilon)$. Then, using the mean value theorem

$$\begin{aligned} \hat{y} - y &= f(x+\epsilon) - f(x) \\ &= f'(x)\epsilon + \frac{f''(x+\theta\epsilon)}{2!}\epsilon^2, \ \theta \in (0,1) \end{aligned}$$

giving

$$\frac{\hat{y} - y}{y} = \left(\frac{x f'(x)}{f(x)}\right)\frac{\epsilon}{x} + O(\epsilon^2)$$

The quantity

$$\kappa(x) = \left| \frac{xf'(x)}{f(x)} \right|$$

is called the *condition number* of f since

$$\left| \frac{\hat{y} - y}{y} \right| \approx \kappa(x) \left| \frac{\epsilon}{x} \right|$$

Thus if $\kappa(x)$ is large the problem is ill-conditioned, that is small perturbations in x can induce large perturbations in the solution y.

2.4.1.5 Example 4.5

Let $y = f(x) = \cos x$. Then we see that

$$\kappa(x) = |x \tan x|$$

and, as we might expect, $\cos x$ is most sensitive close to asymptotes of $\tan x$, such as x close to $\pi/2$.[5] *If we take $x = 1.57$ and $\epsilon = -0.01$ then we find that*

$$\kappa(x) \left| \frac{\epsilon}{x} \right| \approx 12.5577$$

which is a very good estimate of $|(\hat{y} - y)/y| = 12.55739\ldots$.

For the second example we consider the condition number of a system of linear equations $Ax = b$. If we let $\hat{x}$ be the solution of the perturbed equations

$$(A + E)\hat{x} = b$$

then

$$A(\hat{x} - x) = -E\hat{x}, \text{so that } \hat{x} - x = -A^{-1}E\hat{x}$$

giving

$$\frac{\|\hat{x} - x\|}{\|\hat{x}\|} \leq \|A^{-1}\| \cdot \|E\| = (\|A\| \cdot \|A^{-1}\|)\frac{\|E\|}{\|A\|} \tag{6}$$

The quantity

$$\kappa(A) = \|A\| \cdot \|A^{-1}\|$$

is called the condition number of A with respect to the solution of the equations $Ax = b$, or the condition number of A with respect to matrix inversion. Since $I = AA^{-1}$, for any norm such that $\|I\| = 1$, we have that $1 \leq \kappa(A)$, with equality possible for the $1, 2$ and ∞ norms. If A is singular then $\kappa(A) = \infty$.

[5] The given condition number is not valid at $x = \pi/2$, since $\cos \pi/2 = 0$

2.4.1.6 Example 4.6 (Condition of matrix)

For the matrix of Example 4.4 we have that

$$A = \begin{pmatrix} 99 & 98 \\ 100 & 99 \end{pmatrix}, \ \|A\|_1 = 199$$

and

$$A^{-1} = \begin{pmatrix} 99 & -98 \\ -100 & 99 \end{pmatrix}, \ \|A^{-1}\|_1 = 199$$

so that

$$\kappa_1(A) = 199^2 \approx 4 \times 10^4$$

Thus we can see that if A is only accurate to about 4 figures, we cannot guarantee any accuracy in the solution.

The term condition number was first introduced by Turing in the context of systems of linear equations [Turi48]. Note that for an orthogonal or unitary matrix Q, $\kappa(Q) = 1$.

As a third illustration we quote results for the sensitivity of the root of a polynomial. Consider

$$f(x) = a_n x^n + a_{n-1}x^{n-1} + \ldots + a_1 x + a_0$$

and let α be a single root of $f(x)$ so that $f(\alpha) = 0$, but $f'(\alpha) \neq 0$. Let $p(x)$ be the perturbed polynomial

$$p(x) = f(x) = \epsilon g(x), \ g(x) = b_n x^n + b_{n-1}x^{n-1} + \ldots + b_1 x + b_0$$

with root $\hat{\alpha} = \alpha + \delta$, so that $p(\hat{\alpha}) = 0$. Then [[Wilk63],Section 7,Chapter 2] shows that

$$|\delta| \approx \left| \frac{\epsilon g(\alpha)}{f'(\alpha)} \right|$$

Wilkinson also shows that if α is a double root then

$$|\delta| \approx \left| \left(-\frac{2\epsilon g(\alpha)}{f''(\alpha)} \right)^{\frac{1}{2}} \right|$$

2.4.1.7 Example 4.7 (Condition of roots of cubic equation)

For the root $\alpha = x_1 = 1$ of the cubic equation of Example 4.1, with $g(x) = x^3$ and $\epsilon = -0.01$, we have

$$f'(x) = 3x^2 - 42x + 120$$

so that

$$|\delta| \approx \left| \frac{-0.01 \times 1^3}{81} \right| \approx 0.0001$$

and hence this root is very well-conditioned with respect to perturbations in the coefficients of x^3. On the other hand, for the double root $\alpha = 10$, we have

$$f''(x) = 6x - 42$$

so that

$$|\delta| \approx \left| \left(\frac{-2 \times -0.01 \times 10^3}{18} \right)^{\frac{1}{2}} \right| \approx 1.054$$

and this time the perturbation of ϵ produces a rather larger perturbation in the root. Because ϵ is not particularly small the estimate of δ is not particularly accurate, but we do get a good warning of the ill-conditioning.

Highman [[High02],Section 25.4] gives a result for the sensitivity of a root of a general nonlinear equation.

Problems can be ill-conditioned simply because they are poorly scaled, often as the result of a poor choice of measurement units. Some algorithms, or implementation of algorithms, are insensitive to scaling or attempt automatic scaling, but in other cases a good choice of scaling can be important to the success of an algorithm. It is also all too easy to turn a badly scaled problem into a genuinely ill-conditioned problem.

2.4.1.8 Example 4.8 (Badly scaled matrix)

If we let A be the matrix

$$A = \begin{pmatrix} 2 \times 10^9 & 10^9 \\ 10^{-9} & 2 \times 10^{-9} \end{pmatrix}$$

then $\kappa_2(A) \approx 1.67 \times 10^{18}$ and so A is ill-conditioned. However we can row scale A as

$$B = DA = \begin{pmatrix} 10^{-9} & 0 \\ 0 & 10^9 \end{pmatrix} \begin{pmatrix} 2 \times 10^9 & 10^9 \\ 10^{-9} & 2 \times 10^{-9} \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix}$$

for which $\kappa_2(B) = 3$, so that B is well-conditioned. On the other hand if we perform a plane rotation on A with $c = 0.8$, $s = 0.6$ we get

$$\begin{aligned} C = GA &= \begin{pmatrix} 0.8 & 0.6 \\ -0.6 & 0.8 \end{pmatrix} \begin{pmatrix} 2 \times 10^9 & 10^9 \\ 10^{-9} & 2 \times 10^{-9} \end{pmatrix} \\ &= 2 \begin{pmatrix} 8 \times 10^8 + 3 \times 10^{-10} & 4 \times 10^8 + 6 \times 10^{-10} \\ -6 \times 10^8 + 4 \times 10^{-10} & -3 \times 10^8 + 8 \times 10^{-10} \end{pmatrix} \end{aligned}$$

Since G is orthogonal, $\kappa_2(C) = \kappa_2(A) \approx 1.67 \times 10^{18}$, and so C is of course as ill-conditioned as A, but now scaling cannot recover the situation. To see that C is genuinely ill-conditioned, we note that

$$C \approx 2 \times 10^8 \begin{pmatrix} 8 & 4 \\ -6 & -3 \end{pmatrix}$$

which is singular. In double IEEE arithmetic, this would be the floating point represention of C.

Many of the LAPACK routines perform scaling, or have options to equilibrate the matrix in the case of linear equations [[Ande99], Sections 2.4.1 and 4.4.1], [[High02], Sections 7.3 and 9.8], or to balance in the case of eigenvalue problems [[Ande99], Sections 4.8.1.2 and 4.11.1.2].

2.4.2 Stability

The *stability* of a method for solving a problem is concerned with the sensitivity of the method to (rounding) errors in the solution process. A method that guarantees as accurate a solution as the data warrants is said to be stable, otherwise the method is unstable. To emphasise the point we note that, whereas condition is concerned with the sensitivity of the problem, stability is concerned with the sensitivity of the method of solution.

An example of an unstable method is that of (3) for computing sample variance. We now give two more simple illustrative examples.

2.4.2.1 Example 4.9 (Quadratic equation)

Consider the quadratic equation

$$1.6x^2 - 100.1x + 1.251 = 0$$

Four significant figure arithmetic when using the standard formula

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

gives

$$x_1 = 62.53,\ x_2 = 0.03125$$

If we use the relationship $x_1 x_2 = c/a$ to compute x_2 from x_1 we instead find that

$$x_2 = 0.01251$$

The correct solution is $x_1 = 62.55$,$x_2 = 0.0125$. We can see that in using the standard formula to compute the smaller root we have suffered from cancellation, since $\sqrt{b^2 - 4ac}$ is close to $(-b)$.

Even a simple problem such as computing the roots of a quadratic equation needs great care. A very nice discussion is to be found in [Fors69].

2.4.2.2 Example 4.10 (Recurrence relation)

Consider the computation of y_n defined by

$$y_n = (1/e) \int_0^1 x^n e^x \, dx \tag{7}$$

where n is a non-negative integer. We note that, since in the interval $[0, 1]$, $(1/e)e^x$ is bounded by unity, it is easy to show that

$$0 \le y_n \le 1/(n+1) \tag{8}$$

Integrating (7) by parts gives

$$y_n = 1 - n y_{n-1},\ y_0 = 1 - 1/e = 0.6321205882856\ldots \tag{9}$$

and we have a seemingly attractive method for computing y_n for a given value of n. The result of using this forward recurrence relation, with IEEE double precision arithmetic, to compute the values of y_i up to y_21 is shown in Table 2. Bearing in mind the bounds of (8), we see that later values are diverging seriously from the correct solution.

A simple analysis shows the reason for the instability. Since y 0 cannot be represented exactly, we cannot avoid starting with a slightly perturbed value, $\hat{y}_0$. So let

$$\hat{y}_0 = y_0 + \epsilon$$

y_0 0.6321	y_1 0.3679	y_2 0.2642	y_3 0.2073	y_4 0.1709	y_5 0.1455	y_6 0.1268	y_7 0.1124
y_8 0.1009	y_9 0.0916	y_{10} 0.0839	y_{11} 0.0774	y_{12} 0.0718	y_{13} 0.0669	y_{14} 0.0627	y_{15} 0.0590
y_{16} 0.0555	y_{17} 0.0572	y_{18} -0.0295	y_{19} 1.5596	y_{20} -30.1924	y_{21} 635.0403		

Table 2: Forward Recurrence for y_n

Then, even if the remaining computations are performed exactly we see that

$$\begin{array}{rcccl} \hat{y}_1 & = & 1 - \hat{y}_0 & = & y_1 - \epsilon \\ \hat{y}_2 & = & 1 - 2\hat{y}_1 & = & y_2 + 2\epsilon \\ \hat{y}_3 & = & 1 - 3\hat{y}_2 & = & y_3 - 6\epsilon \\ \hat{y}_4 & = & 1 - 4\hat{y}_3 & = & y_4 + 24\epsilon \end{array}$$

and a straightforward inductive proof shows that

$$\hat{y}_n = y_n + (-1)^n n!\epsilon$$

When $n = 21$,$n! \approx 5.1091 \times 10^{19}$. We see clearly that this forward recurrence is an unstable method of computing y_n, since the error grows rapidly as we move forward.

The next example illustrates a stable method of computing y_n.

2.4.2.3 Example 4.11 (Stable recurrence)

Rearranging (9) we obtain the backward recurrence

$$y_{n-1} = (1 - y_n)/n$$

Suppose that we have an approximation, $\hat{y}_{n+m}$, to y_{n+m} and we let

$$\hat{y}_{n+m} = y_{n+m} + \epsilon$$

Then, similarly to the result of Example 4.10, we find that

$$\hat{y}_n = y_n + \frac{(-1)^{m-n}\epsilon}{(n+m)(n+m-1)\dots(n+1)}$$

and this time the initial error decays rapidly, rather than grows rapidly as in Example 4.10. If we take an initial guess of $y_{21} = 0$, we see from (8) that

$$|\epsilon| \leq 1/21 \leq 0.05$$

Using this backward recurrence relation, with IEEE double precision arithmetic, gives the value

$$y_0 = 0.63212055882856$$

which is correct to all the figures shown. We see that this backward recurrence is stable.

It should also be said that the integral of (7) can be evaluated stably without difficulty using a good numerical integration (quadrature) formula, since the function $f(x) = (1/e)x^n e^x$ is non-negative and monotonic throughout the interval [0,1].

In the solution of ordinary and partial differential equations one form of instability can arise by replacing a differential equation by a difference equation. We first illustrate the problem by the solution of a simple nonlinear equation.

2.4.2.4 Example 4.12 (Parasitic solution)

The equation

$$e^{-x} = 99x \tag{10}$$

has a solution close to $x = 0.01$. By expanding e^{-x} as a power series we have that

$$e^{-x} = 1 - x + \frac{x^2}{2!} - \frac{x^3}{3!} + \dots \approx 1 - x + \frac{x^2}{2!}$$

and hence an approximate solution of (10) is a root of the quadratic equation

$$x^2 - 200x + 2 = 0$$

which has the two roots $x_1 \approx 0.0100005$, $x_2 \approx 199.99$. The second root clearly has nothing to do with the original equation and is called a **parasitic** *solution.*

In the above example we are unlikely to be fooled by the parasitic solution, since it so clearly does not come close to satisfying (10). But in the solution of ordinary or partial differential equations such bifurcurations, due to truncation error, may not be so obvious.

2.4.2.5 Example 4.13 (Instability for ODE)

For the initial value problem

$$y' = f(x, y),\ y = y_0 \text{ when } x = x_0 \tag{11}$$

the mid-point rule, or leap-frog method, for solving the differential equation is given by

$$y_{r+1} = y_{r-1} + 2hf_r \tag{12}$$

where $h = x_i - x_{i-1}$ *for all* i *and* $f_r = f(x_r, y_r)$*. This method has a truncation error of* $O(h^3)$ *[[Isaa94], Section 1.3, Chapter 8]*[6] *This method requires two starting values, so one starting value must be estimated by some other method. Consider the case where*

$$f(x, y) = \alpha y,\ y_0 = 1,\ x_0 = 0$$

so that the solution of (11) is $y = e^{\alpha x}$*. Figures 6 and 7 show the solution obtained by using (12) when* $h = 0.1$ *for the cases* $\alpha = 2.5$ *and* $\alpha = -2.5$ *respectively. In each case the value of* y_1 *is taken as the correct four figure value,* $y_1 = 1.284$ *when* $\alpha = 2.5$ *and* $y_1 = 0.7788$ *when* $\alpha = -2.5$*. We see that in the first case the numerical solution does a good job in following the exact solution, but in the second case oscillation sets in and the numerical solution diverges from the exact solution.*

The reason for this behaviour in the above example is that (12) has the solution

$$y_r = A\left(\alpha h + (1 + \alpha^2 h^2)^{\frac{1}{2}}\right)^r + B\left(\alpha h - (1 + \alpha^2 h^2)^{\frac{1}{2}}\right)^r \tag{13}$$

where A and B are constants that depend on the intial conditions. With the initial conditions $y_0 = 1$, $x_0 = 0$ and $y_1 = e^h$, $x_1 = h$ we find that $A = 1 + O(h^3)$, $B = O(h^3)$. We can see that the first term in (13) approximates the exact solution, but the second term is a parasitic solution. When $\alpha > 0$ the exact solution increases and the parasitic solution decays, and so is harmless, but when $\alpha < 0$ the exact solution decays and the parasitic solution grows as illustrated in Figure 7. An entertaining discussion, in the context of the Milne-Simpson method, of the above phenomenon is given in Acton [[Acto70], Chapter 5], a book full of good advice and insight. A more recent book by Action in the same vein is [Acto96].

[6] Here it is called the centered method. It is an example of a Nyström method.

Figure 6: Stable ODE Example

Figure 7: Unstable ODE Example

2.4.3 Error Analysis

Error analysis is concerned with analysing the cumulative effects of errors. Usually these errors will be rounding or truncation errors. For example, if the polynomial

$$p(x) = p_0 + p_1 x + p_2 x^2 + \cdots + p_n x^n$$

is evaluated at some point $x = \alpha$ using Horner's scheme (nested multiplication) as

$$p(\alpha) = p_0 + \alpha(p_1 + \cdots + \alpha(p_{n-2} + \alpha(p_{n-1} + \alpha p_n)) \ldots)$$

we might ask under what conditions, if any, on the coefficients $p_0, p_1, \ldots, p_n$ and α, the solution will, in some sense, be reasonable? To answer the question we need to perform an error analysis.

Error analysis is concerned with establishing whether or not an algorithm is stable for the problem in hand. A *forward error analysis* is concerned with how close the computed solution is to the exact solution. A *backward error analysis* is concerned with how well the computed

solution satisfies the problem to be solved. On first acquaintance, that a backward error analysis, as opposed to a forward error analysis, should be of interest often comes as a surprise. The next example illustrates the distinction between backward and forward errors.

2.4.3.1 Example 4.14 (Linear equations)

Let

$$A = \begin{pmatrix} 99 & 98 \\ 100 & 99 \end{pmatrix} \text{ and } b = \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

Then the exact solution of the equations $Ax = b$ is given by

$$x = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Also let $\hat{x}$ be an approximate solution to the equations and define the **residual** *vector r as*

$$r = b - A\hat{x} \tag{14}$$

Of course, for the exact solution $r = 0$ and we might hope that for a solution close to x, r should be small. Consider the approximate solution

$$\hat{x} = \begin{pmatrix} 2.97 \\ -2.99 \end{pmatrix}, \text{ for which } \hat{x} - x = \begin{pmatrix} 1.97 \\ -1.99 \end{pmatrix}$$

and so $\hat{x}$ looks to be a rather poor solution. But for this solution we have that

$$r = \begin{pmatrix} -0.01 \\ 0.01 \end{pmatrix}$$

and we have almost solved the original problem. On the other hand the approximate solution

$$\hat{x} = \begin{pmatrix} 1.01 \\ -0.99 \end{pmatrix}, \text{ for which } \hat{x} - x = \begin{pmatrix} 0.01 \\ 0.01 \end{pmatrix}$$

gives

$$r = \begin{pmatrix} -1.97 \\ -1.97 \end{pmatrix}$$

and, although $\hat{x}$ is close to x, it does not solve a problem close to the original problem.

Once we have computed the solution to a system of linear equations $Ax = b$ we can, of course, readily compute the residual of (14). If we can find a matrix E such that

$$E\hat{x} = r \tag{15}$$

then

$$(A + E)\hat{x} = b$$

and we thus have a measure of the perturbation in A required to make $\hat{x}$ an exact solution. A particular E that satisfies (15) is given by

$$E = \frac{r\hat{x}^T}{\hat{x}^T\hat{x}}$$

From this equation we have that

$$\|E\|_2 \leq \frac{\|r\|_2\|\hat{x}\|_2}{\|\hat{x}\|_2^2} = \frac{\|r\|_2}{\|\hat{x}\|_2}$$

Thus, this particular E minimizes $\|E\|_2$. Since $x^T x = \|x\|_F^2$ it also minimizes E in the Frobenious norm. This gives us an *a posteriori* bound on the backward error.

2.4.3.2 Example 4.15 (Perturbation in linear equations)

Consider the equations $Ax = b$ of Example 4.14 and the 'computed' solution

$$\hat{x} = \begin{pmatrix} 2.97 \\ -2.99 \end{pmatrix} \text{ for which } r = \begin{pmatrix} -0.01 \\ 0.01 \end{pmatrix}$$

Then

$$r\hat{x}^T = \begin{pmatrix} -0.0297 & 0.0299 \\ 0.0297 & -0.0299 \end{pmatrix}, \ \hat{x}^T\hat{x} = 17.761$$

and

$$E \approx \begin{pmatrix} -0.00167 & 0.00168 \\ 0.00167 & -0.00168 \end{pmatrix}$$

Note that $\|E\|_F/\|A\|_F \approx 1.695 \times 10^{-5}$ and so the computed solution corresponds to a small relative perturbation in A.

From (6) we have that

$$\frac{\|\hat{x} - x\|}{\|\hat{x}\|} \leq \kappa(A)\frac{\|E\|}{\|A\|}$$

and so, if we know $\kappa(A)$, then an estimate of the backward error allows us to estimate the forward error.

As a general rule, we can say that approximately:

$$\text{forward error} \ \leq \ \text{condition error} \ \times \ \text{backward error}$$

Although the idea of backward error analysis had been introduced by others, it was James Hardy Wilkinson who really developed the theory and application, and gave us our understanding of error analysis and stability, particularly in the context of numerical linear algebra. See the classic books [Wilk63] and [Wilk65].

A wonderful modern book that continues the Wilkinson tradition is [High02]. The solid foundation for the numerical linear algebra of today relies heavily on the pioneering work of Wilkinson; see also [Wilk71][7]

[7] In Givens 1954 technical report quoted earlier [Give54], which was never published in full and must be one of the most oft quoted technical reports in numerical analysis, as well as the introduction of Givens plane rotations, it describes the use of Sturm sequences for computing eigenvalues of tridiagonal matrices, and contains probably the first explicit backward error analysis. Wilkinson, who so successfully developed and expounded the theory and analysis of rounding errors, regarded the *a priori* error analysis of Givens as "one of the landmarks in the history of the subject" [[Wilk65], Additional notes to Chapter 5]

Wilkinson recognised that error analysis could be tedious and often required great care, but was nevertheless essential to our understanding of the stability of algorithms.

> "The clear identification of the factors determining the stability of an algorithm soon led to the development of better algorithms. The proper understanding of inverse iteration for eigenvectors and the development of the QR algorithm by Francis are the crowning achievements of this line of research.
>
> For me, then, the primary purpose of the rounding error analysis was insight. [Wilk86], p. 197.

As a second example to illustrate forward and backward errors, we consider the quadratic equation of Example 4.9.

2.4.3.3 Example 4.16 (Errors in quadratic equation)

For the quadratic equation of Example 4.9 we saw that the standard formula gave the roots $x_1 = 62.53$, $x_2 = 0.03125$. *Since the correct solution is* $x_1 = 62.55$, $x_2 = 0.0125$ *the second root has a large forward error. If we form the quadratic* $q(x) = 1.6(xx_1)(xx_2)$, *rounding the answer to four significant figures, we get*

$$q(x) = 1.6x^2 - 100.1x + 3.127$$

and the constant term differs significantly from the original value of 1.251, so that there is also a large backward error. The standard method is neither forward nor backward stable. On the other hand, for the computed roots $x_1 = 62.53$, $x_2 = 0.01251$ *we get*

$$q(x) = 1.6x^2 - 100.1x + 1.252$$

so this time we have both forward and backward stability.

An example of a computation that is forward stable, but not backward stable is that of computing the coefficients of the polynomial

$$p(x) = (x - x_1)(x - x_2) \cdots (x - x_n), \ x_i > 0$$

In this case, since the x_i are all of the same sign, no cancellation occurs in computing the coefficients of $p(x)$ and the computed coefficients will be close to the exact coefficients; thus we have small forward errors. On the other hand, as Example 4.1 illustrates, the roots of polynomials can be sensitive to perturbations in the coefficients and so the roots of the computed polynomial could differ significantly from $x_1, x_2, \ldots, x_n$.

2.4.3.4 Example 4.17 (Ill-conditioned polynomial)

The polynomial whose roots are $x_i = i$, $i = 1, 2, \ldots, 20$, *is*

$$p(x) = x^{20} - 210x^{19} + \ldots + 20!$$

Suppose that the coefficient of x^{19} is computed as $-(210 + 2^{-23})$; then we find that x^{16}, $x^{17} \approx 16.73 \pm 2.813i$. Thus a small error in computing a coefficient produced a polynomial with significantly different roots from those of the exact polynomial. This polynomial is discussed in Wilkinson [[Wilk63], Chapter 2, Section 9] and [Wilk84]. See also Wilkinson [[Wilk85], Section 2].

2.5 Floating Point Error Analysis

Floating point error analysis is concerned with the analysis of errors in the presence of floating point arithmetic. It is based on the relative errors that result from each basic operation. We give just a brief introduction to floating point error analysis in order to illustrate the ideas.

Let x be a real number; then we use the notation $\mathrm{fl}(x)$ to represent the floating point value of x. The fundamental assumption is that

$$fl(x) = x(1+\epsilon), \ |\epsilon| \leq u \tag{16}$$

where u is the unit roundoff of (1). Of course,

$$\frac{fl(x) - x}{x} = \epsilon$$

A useful alternative is

$$fl(x) = \frac{x}{1+\delta}, \ |\delta| \leq u, \text{ so that } \frac{fl(x) - x}{fl(x)} = \delta \tag{17}$$

2.5.1 Example 5.1 (Floating point numbers)

Consider four figure decimal arithmetic with

$$u = \frac{1}{2} \times 10^{-3} = 5 \times 10^{-4}$$

If $x = \sqrt{2} = 1.414213\ldots$ then $fl(x) = 1.414$ and

$$|\epsilon| = \left| \frac{fl(x) - x}{x} \right| \approx 1.5 \times 10^{-4}$$

If $x = 1.000499\ldots$ then $fl(x) = 1.000$ and

$$|\epsilon| = \left| \frac{fl(x) - x}{x} \right| \approx 5 \times 10^{-4} = u$$

If $x = 1000.4999\ldots$ then fl(x)=1000 and again

$$|\epsilon| = \left| \frac{fl(x) - x}{x} \right| \approx 5 \times 10^{-4} = u$$

Bearing in mind (16), if x and y are floating point numbers, then the standard model of floating point arithmetic, introduced by Wilkinson [Wilk60], is given by

$$fl(x \otimes y) = (x \otimes y)(1+\epsilon),\ |\epsilon| \leq u$$

$$\text{where } \otimes \equiv +, -, \times, \div$$

It is assumed, of course, that $x \otimes y$ produces a value that is in the range of representable floating point numbers. Comparable to (17), a useful alternative is

$$fl(x \otimes y) = \frac{x \otimes y}{1+\delta},\ |\delta| \leq u$$

When we consider a sequence of floating point operations we frequently obtain products of error terms of the form

$$(1+\epsilon) = (1+\epsilon_1)(1+\epsilon_2)\ldots(1+\epsilon_r)$$

so that

$$(1-u)^r \leq 1+\epsilon \leq (1+u)^r$$

If we ignore second order terms then we have the reasonable assumption that[8]

$$|\epsilon| \leq ru \tag{19}$$

We now give three illustrative examples. In all three examples the x_i are assumed to be floating point numbers, that is, they are values that are already represented in the computer. This is, of course, a natural assumption to make when we are analysing the errors in a computation.

2.5.2 Example 5.2 (Product of values)

Let $x = x_0x_1\ldots x_n$ and $\tilde{x} = fl(x)$. Thus we have n products to form, each one introducing an error bounded by u. Hence from (18) we get

$$\tilde{x} = x_0x_1(1+\epsilon_1)x_2(1+\epsilon_2)\ldots x_n(1+\epsilon_n),\ |\epsilon_i| \leq u \tag{20}$$

and from (19) we see that

$$\tilde{x} = x(1+\epsilon),\ |\epsilon| \leq nu \tag{21}$$

where

$$1+\epsilon = (1+\epsilon_1)(1+\epsilon_2)\ldots(1+\epsilon_n)$$

We can see from (21) that this computation is forward stable, because the result is close to the exact result, and from (20) the computation is also backward stable, because the result is exact for a slightly perturbed problem; that is the result is exact for the data x_0,$x_1(1+\epsilon_1)$,$x_2(1+\epsilon_2)$,...,$x_n(1+\epsilon_n)$.

[8]Those who are uncomfortable with the approximation may prefer to replace the bound $|\epsilon| \leq ru$ with one of the form $|\epsilon| \leq \gamma_r$, where $\gamma_r = (ru)/(1-ru)$ and $ru < 1$ is assumed. See [High02], Lemma 3.1

2.5.3 Example 5.3 (Sum of values)

Let $s = x_1 + x_2 + \ldots + x_n$ *and* $\tilde{s} = fl(s)$. *By considering*

$$s_r = fl(s_{r-1} + x_r),\ s_1 = x_1$$

it is straightforward to show that

$$\begin{aligned} \tilde{s} &= x_1(1+\epsilon_1) + x_2(1+\epsilon_1) + x_3(1+\epsilon_2) + \ldots + x_n(1+\epsilon n - 1) \\ &= x + (x_1\epsilon_1 + x_2\epsilon_1 + x_3\epsilon_2 + \ldots + x_n\epsilon_{n-1}),\ |\epsilon_r| \leq (n-r+1)u \end{aligned}$$

Here we see that summation is backward stable, but is not necessarily forward stable. Example 3.1 gives a case where summation is not forward stable, but notice that the computed solution is the exact solution of the slightly perturbed problem

$$1.000 + 1.000 \times 10^4 - 1.0001 \times 10^4 = 0$$

which illustrates the backward stability.

Note that if the x_i all have the same sign, then summation is forward stable because

$$|\tilde{s} - s| \leq (|x_1| + |x_2| + \ldots + |x_n|)nu = |s|nu$$

so that

$$\frac{|\tilde{s} - s|}{|s|} \leq nu,\ s \neq 0$$

2.5.4 Example 5.4 (Difference of two squares)

Consider the computation

$$z = x^2 - y^2 \tag{22}$$

We can, of course, also express z *as*

$$z = (x+y)(x-y) \tag{23}$$

If we compute z *from (22) we find that*

$$\begin{aligned} \tilde{z} &= fl(z^2 - y^2) = x^2(1+\epsilon_1) = y^2(1 = \epsilon_2) \\ &= z + (x^2\epsilon_1 - y^2\epsilon_2),\ \epsilon_1, \epsilon_2 \leq 2u \end{aligned}$$

and so this is backward stable, but not forward stable. On the other hand, if we compute z *from (23)*

$$\begin{aligned} \hat{z} &= fl((x+y)(x-y)) = (x+y)(x-y)(1+\epsilon) \\ &= z(1+\epsilon),\ \epsilon \leq 3u \end{aligned}$$

and so this is both backward and forward stable. As an example, if we take

$$x = 543.2,\ y = 543.1, \quad \text{so that } z = 108.63$$

and use four significant figure arithmetic we find that

$$\tilde{z} = 100, \ but \hat{z} = 108.6$$

Clearly $\tilde{z}$ has suffered from cancallation, but $\hat{z}$ has not.

We now quote some results, without proof, of solving higher level linear algebra problems to illustrate the sort of results that are possible. Principally we consider the solution of the n linear equations

$$Ax = b \tag{24}$$

by Gaussian elimination and we assume that the reader is familiar with Gaussian elimination. The kth step of Gaussian elimination can be expressed as

$$A_k = M_k P_k A_{k-1} Q_k, \ A_0 = A \tag{25}$$

where P_k and Q_k are permutation matrices, one or both of which may be the unit matrix, chosen to implement whatever pivoting strategy is used and M_k is the multiplier matrix chosen to eliminate the elements below the diagonal of the kth column of A_{k1}. This results in the factorization

$$A = PLUQ$$

where P and Q are permutation matrices, L is a unit lower triangular matrix and U is upper triangular. To simplify analysis it is usual to assume that, with hindsight, A has already been permuted so that we can work with $A \Leftarrow P^T A Q^T$. In this case (25) becomes

$$A_k = M_k A_{k-1}, \ A_0 = A$$

and M_k and A_{k-1} have the form

$$M_k = \begin{pmatrix} I & 0 & 0 \\ 0 & 1 & 0 \\ 0 & -m_k & I \end{pmatrix}, \ A_{k-1} = \begin{pmatrix} U_{k-1} & u_{k-1} & X_{k-1} \\ 0 & \alpha_{k-1} & b_{k-1}^T \\ 0 & a_{k-1} & \hat{A}_{k-1} \end{pmatrix}$$

m_k is chosen to eliminate a_{k-1}, so that

$$a_{k-1} - \alpha_{k-1} m_k = 0, \quad \text{giving } m_k = a_{k-1}/\alpha_{k-1}$$

$\hat{A}_{k-1}$ is updated as

$$\tilde{A}_k = \hat{A}_{k-1} - m_k b_{k-1}^T \equiv \begin{pmatrix} \alpha_k & b_k^T \\ a_k & \hat{A}_k \end{pmatrix}$$

and

$$A = LU, \quad \text{where } L = M_1^{-1} M_2^{-1} \ldots M_{n-1}^{-1}, \quad \text{and } U = A_{n-1}$$

Since

$$M_k^{-1} = \begin{pmatrix} I & 0 & 0 \\ 0 & 1 & 0 \\ 0 & m_k & I \end{pmatrix}$$

we have that

$$L = \begin{pmatrix} 1 & 0 & \cdots & 0 & 0 \\ m_{21} & 1 & \cdots & 0 & 0 \\ m_{31} & m_{32} & \cdots & 0 & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ m_{n-1,1} & m_{n-1,2} & \cdots & 1 & 0 \\ m_{n1} & m_{n2} & \cdots & m_{n,n-1} & 1 \end{pmatrix}$$

It can be shown that the computed factors $\tilde{L}$ and $\tilde{U}$ satisfy

$$\tilde{L}\tilde{U} = A + F$$

where various bounds on F are possible; for example, for the 1, ∞ or F norms

$$\|F\| \leq 3ngu\|A\|, \;\; g = \frac{\max\|\tilde{A}_k\|}{\|A\|}$$

g is called the *growth factor*. Similarly it can be shown that the computed solution of (24), $\tilde{x}$, satisfies

$$(A + E)\hat{x} = b$$

where a typical bound is

$$\|E\| \leq 3n^2gu\|A\|$$

We can see that this bound is satisfactory unless g is large, so it is important to choose P or Q, or both, in order to control the size of g. This is essentially the classic result of Wilkinson[Wilk61] and Wilkinson [[Wilk63], Section 25], where the ∞-norm is used and the use of partial pivoting is assumed; see also Higham [[High02], Theorem 9.5].

The next example gives a simple demonstration of the need for pivoting.

2.5.5 Example 5.5 (The need for pivoting)

Consider the matrix

$$A = \begin{pmatrix} 0.001 & 12 \\ 10 & -10 \end{pmatrix}$$

and the use of four significant figure arithmetic. Since this is just a two by two matrix we have that $M_1^{-1} = L$ *and* $M_1 A = U$. *Denoting the computed matrix* X *by* $\tilde{X}$, *we find that*

$$L = \tilde{L} = \begin{pmatrix} 1 & 0 \\ 10000 & 1 \end{pmatrix}, \; U = \begin{pmatrix} 0.001 & 12 \\ 0 & -120010 \end{pmatrix} \text{ and } \tilde{U} = \begin{pmatrix} 0.001 & 12 \\ 0 & -120000 \end{pmatrix}$$

which gives

$$U = \tilde{U} = \begin{pmatrix} 0 & 0 \\ 0 & 10 \end{pmatrix}$$

and

$$F = \tilde{L}\tilde{U} = A - \begin{pmatrix} 0 & 0 \\ 0 & 10 \end{pmatrix} = U - \tilde{U}$$

Thus whilst $\|F\|$ is small relative to $\|U\|$, it corresponds to a large relative perturbation in $\|A\|$. On the other hand if we permute the two rows of A to give

$$\overline{A} = \begin{pmatrix} 10 & -10 \\ 0.001 & 12 \end{pmatrix}$$

we have that

$$L = \tilde{L} = \begin{pmatrix} 1 & 0 \\ 0.0001 & 1 \end{pmatrix}, \; U = \begin{pmatrix} 10 & -10 \\ 0 & 12.001 \end{pmatrix} \text{ and } \tilde{U} = \begin{pmatrix} 10 & -10 \\ 0 & 12.00 \end{pmatrix}$$

which gives

$$U - \tilde{U} = \begin{pmatrix} 0 & 0 \\ 0 & -0.001 \end{pmatrix}$$

and

$$F = \tilde{L}\tilde{U} - A = \begin{pmatrix} 0 & 0 \\ 0 & -0.001 \end{pmatrix} = U - \tilde{U}$$

This time $\|F\|$ is small relative to both $\|U\|$ and $\|A\|$.

If we put $m = \max|\tilde{m}_{ij}|$ then we can show that

$$g \leq (1+m)^{n-1}$$

Partial pivoting ensures that

$$m \leq 1 \text{ and hence } g \leq 2^{n-1}$$

Only very special examples get anywhere near this bound, one example due to Wilkinson being matrices of the form

$$A = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 & 1 \\ -1 & 1 & 0 & \cdots & 0 & 1 \\ -1 & -1 & 1 & \cdots & 0 & 1 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ -1 & -1 & -1 & \cdots & 1 & 1 \\ -1 & -1 & -1 & \cdots & -1 & 1 \end{pmatrix} \text{ for which } U = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 & 1 \\ 0 & 1 & 0 & \cdots & 0 & 2 \\ 0 & 0 & 1 & \cdots & 0 & 4 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 2^{n-2} \\ 0 & 0 & 0 & \cdots & 0 & 2^{n-1} \end{pmatrix}$$

Despite such examples, in practice partial pivoting is the method of choice, but careful software should at least include an option to monitor the growth factor.

There are classes of matrices for which pivoting is not needed to control the growth of g [[High02], Table 9.1]. Perhaps the most important case is that of symmetric positive definite matrices for which it is known a priori that growth cannot occur, and so Gaussian elimination is stable when applied to a system of equations for which the matrix of coefficients is symmetric positive definite[9]

[9] The variant of Gaussian elimination that is usually used in this case is *Cholesky's method*

The choice of pivots is affected by scaling and equilibration, and a poor choice of scaling can lead to a poor choice of pivots. A full discussion on pivoting strategies, equilibration and scaling, as well as sage advice, can be found in [High02].

For methods that use orthogonal transformations we can usually obtain similar error bounds, but without the growth factor, since orthogonal transformations preserve the 2norm and Fnorm. For example, if we use Householder transformations to perform a QR factorization of A for the solution of the least squares problem $\min_x \|b - Ax\|_2$, where A is an m by n, $m \geq n$ matrix of rank n [Golu65], the computed solution $\tilde{x}$ satisfies

$$\min_x \|(b + f) - (A + E)\tilde{x}\|_2$$

where f and E satisfy bounds of the form

$$\|f\|_F \leq c_1 mnu\|b\|_F, \ \|E\|_F \leq c_2 mnu\|A\|_F$$

and c_1 and c_2 are small integer constants [[Laws95], page 90].

Similarly, for the solution of the eigenvalue problem $Ax = \lambda x$, where A is an n by n matrix, using Housholder transformations to reduce A to upper Hessenberg form, followed by the QR algorithm to further reduce the Hessenberg form to upper triangular Schur form, the computed solution satisifies

$$(A + E)\tilde{x} = \tilde{\lambda}\tilde{x}$$

where

$$\|E\|_F \leq p(n)u\|A\|_F$$

and $p(n)$ is a modestly growing function of n [Wilk65]; [Ande99].

We note that the bounds discussed so far are called *normwise* bounds, but in many cases they can be replaced by *componentwise* bounds which bound the absolute values of the individual elements, and so are rather more satisfactory. For instance, if A is a sparse matrix, we would probably prefer not to have to perturb the elements that are structurally zero. As a simple example, consider the triangular equations

$$Tx = b, \ T - n \text{ by } n \text{ triangular}$$

and let $\tilde{x}$ be the solution computed by forward or backward substitution, depending on whether T is lower or upper triangular respectively. Then it can readily be shown that $\tilde{x}$ satisifes

$$(T + E)\tilde{x} = b, \quad \text{with } |e_{ij}| \leq nu|t_{ij}|$$

which is a strong componentwise result showing backward stability [[High02], Theorem 8.5].

Associated with componentwise error bounds are componentwise condition numbers. Once again see [High02] for further details and references.

2.6 Posing the Mathematical Problem

In this short section we merely wish to raise awareness of the need to model a problem correctly, without offering any profound solution.

It can be all too easy to transform a well-conditioned problem into an ill-conditioned problem. For instance, in Example 4.10 we transformed the well-conditioned quadrature problem of finding

$$y_n = (1/e) \int_0^1 x^n e^x \, dx, \; n \geq 0$$

into the ill-conditioned problem of finding y_n from the forward recurrence relation

$$y_n = 1 - n y_{n-1}, \; y_0 = 1 - 1/e$$

As another example, we noted in Section 4.3 that polynomials can be very ill-conditioned. It follows that the eigenvalues of a matrix A should most certainly not be computed via the characteristic equation of A. For example, if A is a symmetric matrix with eigenvalues $\lambda i = i, \; i = 1, 2, \ldots, 20$, then the characteristic equation of A, $\det(A - \lambda A)$, is very ill-conditioned (see Example 4.17).

On the other hand, the eigenvalues of a symmetric matrix are always well-conditioned [[Wilk65], Section 31, Chapter 2].

The above two examples illustrate the dangers in transforming the mathematical problem. Sometimes it can be poor modelling of the physical problem that gives rise to an ill-conditioned mathematical problem, and so we need to think carefully about the whole modelling process.

We cannot blame software for giving us poor solutions if we provide the wrong problem. We can, of course, hope that the software might provide a measure for the condition of the problem, or some measure of the accuracy of the solution to give us warning of a poorly posed problem.

At the end of Section 4.1 we also mentioned the desirability of careful choice of measurement units, in order to help avoid the effects of poor scaling.

2.7 Error Bounds and Software

In this section we give examples of reliable software that return information about the quality of the solution. Firstly we look at the freely available software package LAPACK [Ande99], and then at an example of a commercial software library, the NAG Library [NAGa05]. The author of this report has to declare an interest in both of these software products; he is one of the authors of LAPACK and is currently a software developer employed by NAG Ltd. Naturally, the examples are chosen because of familiarity with the products and belief in them as quality products, but I have nevertheless tried not to introduce bias.

LAPACK stands for Linear Algebra PACKage and is a numerical software package for the solution of dense and banded linear algebra problems aimed at PCs, workstations and high-performance shared memory machines. One of the aims of LAPACK was to make the

software efficient on modern machines, whilst retaining portability, and to this end it makes extensive use of the Basic Linear Algebra Subprograms (BLAS), using block-partitioned algorithms based upon the Level 3 BLAS wherever possible. The BLAS specify the interface for a set of subprograms for common scalar and vector (Level 1), matrix-vector (Level 2) and matrix-matrix operations (Level 3). Their motivation and specification are given in [Laws79], [Dong88a] [Dong90] respectively. Information on block-partitioned algorithms and performance of LAPACK can be found in [[Ande99], Chapter 3]. See also [Golu96], particularly Section 1.3, and [Stew98], Chapter 2, which also has some nice discussion on computation.

LAPACK has routines for the solution of systems of linear equations, linear least squares problems, eigenvalue and singular value problems, including generalized problems, as well as routines for the underlying computational components such as matrix factorizations. In addition, a lot of effort was expended in providing condition and error estimates. Quoting from the first paragraph of Chapter 4 Accuracy and Stability of the LAPACK Users Guide:

> In addition to provide faster routines than previously available. LAPACK provides more comprehensive and better error bounds. Our goal is to provide error bounds for most quantities computed by LAPACK.

In many cases the routines return the bounds directly; in other cases the Users' Guide gives details of error bounds and provides code fragments to compute the bounds.

As an example, routine DGESVX[10] solves a system of linear equations $AX = B$, where B is a matrix of one or more right-hand sides, using Gaussian elimination with partial pivoting. Part of the interface is

```
SUBROUTINE DGESVX(..., RCOND, FERR, BERR, WORK, ..., INFO)
```

where the displayed arguments return the following information:

- `RCOND` - Estimate of reciprocal of condition number, $1/\kappa(A)$
- `FERR(`j`)` - Estimated forward error for X_j
- `BERR(`j`)` - Componentwise relative backward error for X_j (smallest relative change in any element of A and B_j that makes X_j an exact solution)
- `WORK(1)` - Reciprocal of pivot growth factor, $1/g$
- `INFO` - Returns a positive value if the computed triangular factor U is singular or nearly singular.

Thus DGESVX is returning all the information necessary to judge the quality of the computed solution.

The routine returns an estimate of $1/\kappa(A)$, rather than $\kappa(A)$ to avoid overflow when A is singular, or very ill-conditioned. The argument INFO is the LAPACK warning or error flag,

[10] In the LAPACK naming scheme the D stands for double precision, GE for general matrix, SV for solver and X for expert driver

and is present in all the LAPACK user callable routines. It returns zero on successful exit, a negative value if an input argument is incorrectly supplied, for example $n < 0$, and a positive value in the case of failure, or near failure as above. In the above example, INFO returns the value i if $u_{ii} = 0$, in which case no solution is computed since U is exactly singular, but returns the value $n+1$ if $1/\kappa(A) < u$, in which case A is non-singular to working precision. In the latter case a solution is returned, and so INFO $= n+1$ acts as a warning that the solution may have no correct digits. The routine also has the option to equilibrate the matrix A. See the documentation of the routine for further information, either in the Users Guide, or in the source code available from netlib at `http://www.netlib.org/lapack/index.html`.

As a second example from LAPACK, routine DGEEVX solves the eigenproblem $Ax = \lambda x$ for the eigenvalues and eigenvectors, $\lambda_i, x_i, i = 1, 2, \ldots, n$ of the n by n matrix A. Optionally, the matrix can be balanced and the left eigenvectors of A can also be computed. Part of the interface is

```
SUBROUTINE DGEEVX(..., ABNRM, RCONDE, RCONDV, ...)
```

where the displayed arguments return the following information:

- `ABNRM` - Norm of the balanced matrix
- `RCONDE(`i`)` - Reciprocal of the condition number of the ith eigenvalue, s_i
- `RCONDV(`i`)` - Reciprocal of the condition number for the ith eignevector, sep_i

Following a call to DGEEVX, approximate error bounds for the computed eigenvalues and eigen- vectors, say EERRBD(i) and VERRBD(i), such that

$$|\tilde{\lambda_i} - \lambda_i| \leq \texttt{EERRBD}(i)$$

$$\theta(\tilde{\nu}_i, \nu_i) \leq \texttt{VERRBD}(i)$$

where $\theta(\tilde{\nu}_i, \nu_i)$ is the angle between the computed and true eigenvector, may be returned by the following code fragment, taken from the Users' Guide:

```
      EPSMCH = DLAMCH('E')
      DO 10 I = 1, N
        EERRBD(I) = EPSMCH*ABNRM/RCONDE(I)
        VERRBD(I) = EPSMCH*ABNRM/RCONDV(I)
10    CONTINUE
```

These bounds are based upon Table 3, extracted from Table 4.5 of the LAPACK Users Guide, which gives approximate asymptotic error bounds for the nonsymmetric eigenproblem. These bounds

Simple eigenvalue	$\lvert\tilde{\lambda_i} - \lambda_i\rvert \lesssim \lVert E\rVert_2/s_i$
Eigenvector	$\theta(\tilde{\nu}_i, \nu_i) \lesssim \lVert E\rVert_F/\text{sep}_i$

assume that the eigenvalues are simple eigenvalues. In addition if the problem is ill-conditioned, these bounds may only hold for extremely small $\|E\|_2$ and so the Users Guide also provides a table of global error bounds which are not so restrictive on $\|E\|_2$. The tables in the Users Guide include bounds for clusters of eigenvalues and for invariant subspaces, and these bounds can be estimated using DGEESX in place of DGEEVX. For further details see The LAPACK Users Guide [[Ande99], Chapter 4] and for further information see [Golu96], Chapter 7 and [Stew90].

LAPACK is freely available via netlib[11], is included in the NAG Fortran 77 Library and is the basis of the dense linear algebra in the NAG Fortran 90 and C Libraries. Tuned versions of a number of LAPACK routines are included in the NAG Fortran SMP Library. The matrix computations of MATLAB have been based upon LAPACK since Version 6 [Math05]; [High05].

We now take an example from the NAG Fortran Library. Routine D01AJF is a general purpose integrator using an adaptive procedure, based on the QUADPACK routine QAGS [Pies83], which performs the integration

$$I = \int_a^b f(x)\ dx$$

where $[a, b]$ is a finite interval. Part of the interface to D01AJF is

```
SUBROUTINE D01AJF(..., EPSABS, EPSREL, RESULT, ABSERR, ...)
```

- `EPSABS` - The absolute accuracy required
- `EPSREL` - The relative accuracy required
- `RESULT` - The computed approximation to I
- `ABSERR` - An estimate of the absolute error

In normal circumstances `ABSERR` satisfies

$$|I - RESULT| \leq ABSERR \leq \max(EPSABS, EPSREL \times |I|)$$

See the NAG Library documentation [NAGb05] and [Pies83] for further details. QUADPACK is freely available from netlib,[12] and a Fortran 90 version of QAGS is available from the more recent quadature package, CUBPACK [Cool03], which is also available from netlib. Typically the error estimate for a quadrature routine is obtained at the expense of additional computation with a finer interval, or mesh, or the use of a higher order quadrature formula.

As a second example from the NAG Library we consider the solution of an ODE. Routine D02PCF integrates

$$y' = f(t, y), \quad \text{given } y(t_0) = y_0$$

[11] `http://www.netlib.org/lapack/index.html`
[12] `http://www.netlib.org/quadpack`

where y is the n element solution vector and t is the independent variable, using a Runge-Kutta method. Following the use of D02PCF, routine D02PZF may be used to compute global error estimates. Part of the interface to D02PZF is

```
SUBROUTINE D02PZF(RMSERR, ERRMAX, TERRMX, ...)
```

where the displayed arguments return the following information:

- `RMSERR(`i`)` - Approximate root mean square error for y_i
- `ERRMAX` - Maximum approximate true error
- `TERRMX` - First point at which maximum approximate true error occurred

The assessment of the error is determined at the expense of computing a more accurate solution using a higher order method to that used for the original solution.

The NAG D02P routines are based upon the RKSUITE software by [Bran92], which is also available from netlib.[13] See also [Sham92] and [Bran93]. A Fortran 90 version of RKSUITE is also available,[14] see [Bran97].

Many routines in the NAG Library attempt to return information about accuracy. The documentation of the routines includes a section labelled "Accuracy" which, when appropriate, gives further advice or information. For instance, the optimization routines generally quote the optimality conditions that need to be met for the routine to be successful. These routines are cautious, and sometimes return a warning, or error, when it is likely that an optimum point has been found, but not all the optimality conditions have been met. NAG and the authors of the routines feel that this is much the best approach for reliability even if users would sometimes prefer that we were more optimistic!

2.8 Other Approaches

What does one do if the software does not provide suitable estimates for the accuracy of the solution, or the sensitivity of the problem? One approach is to run the problem with perturbed data and compare solutions. Of course, the difficulty with this approach is to know how best to choose perturbations. If a small perturbation does significantly change the solution, then we can be sure that the problem is sensitive, but of course we cannot rely on the converse. If we can have trust that the software implements a stable method, then any sensitivity in the solution is due to the problem, but otherwise we cannot be sure whether it is the method or problem that is sensitive.

To help estimate such sensitivity there exists software that uses stochastic methods to give statistical estimates of backward error, or of sensitivity. One such example, PRECISE, is described in [Chai96], Chapter 8 and provides a module for statistical backward error analysis

[13] tt http://www.netlib.org/ode/rksuite/

[14] `http://www.netlib.org/ode/rksuite/` or `http://www.netlib.org/toms/771`

as well as a module for sensitivity analysis. Another example is CADNA[15]; see for example [Vign93].

Another approach to obtaining bounds on the solution is the use of interval arithmetic, in conjunction with interval analysis [Moor79] [Krei05]. Some problems can be successfully solved using interval arithmetic throughout, but for some problems the bounds obtained would be far too pessimistic; however interval arithmetic can often be applied as an posteriori tool to obtain realistic bounds. We note that there is a nice interval arithmetic toolbox for Matlab, INTLAB, by [Rump99] that is freely available[16]; see also [Harg02]. It should be noted that in general, the aim of interval arithmetic is to return forward error bounds on the solution.

2.8.1 Example 8.1 (Cancellation and interval arithmetic)

As a very simple example consider the computation of s in Example 3.1 using four figure interval arithmetic. Bearing in mind that interval arithmetic works with intervals that are guaranteed to contain the exact solution, we find that

$$\begin{aligned} s = [s1\ s2] &= [1.000\ 1.000] + [1.000 \times 10^4\ 1.000 \times 10^4] - [1.000 \times 10^4\ 1.000 \times 10^4] \\ &= [1.000 \times 10^4\ 1.001 \times 10^4] - [1.000 \times 10^4\ 1.000 \times 10^4] \\ &= [0\ 10] \end{aligned}$$

so whilst the result is somewhat pessimistic, it does give due warning of the cancellation.

Finally we comment that one should not be afraid to exert pressure on software developers to provide features that allow one to estimate the sensitivity of the problem and the accuracy of the solution.

2.9 Summary

We have tried to illustrate the niceties of numerical computation and the detail that needs to be considered when turning a numerical algorithm into reliable, robust numerical software. We have also tried to describe and illustrate the ideas that need to be understood to judge the quality of a numerical solution, especially condition, stability and error analysis, including the distinction between backward and forward errors.

We emphasise that one should most certainly be concerned about the quality of computed solutions, and use trustworthy quality software. We cannot just blithely assume that results returned by software packages are correct.

This is not always easy since scientists wish to concentrate on their science and should not really need to be able to analyse an algorithm to understand whether or not it is a stable method for solving their problem. Hence the emphasis in this report on the desirability of software providing proper measures of the quality of the solution.

[15] At the time of writing, a free academic version is available from `http://www-anp.lip6.fr/cadna/Accueil.php`

[16] `http://www.ti3.tu-harburg.de/english/index.html`

We conclude with a question:

> "You have been solving these damn problems better than I can pose them"
> Sir Edward Bullard, Director NPL, in a remark to Wilkinson in the mid 1950s,
> See [Wilk85],p. 11

Software developers should strive to provide solutions that are at least as good as the data deserves.

Chapter 3

Chapter Overview

Each routine in the Basic Linear Algebra Subroutine set (BLAS) [blas01] has a prefix where:

- C - Complex
- D - Double Precision
- S - Real
- Z - Complex*16

Routines in level 2 and level 3 of BLAS use the prefix for type:

- GE - general
- GB - general band
- SY - symmetric
- HE - hermitian
- TR - triangular
- SB - symmetric band
- HB - hermetian band
- TB - triangular band
- SP - Sum packed
- HP - hermitian packed
- TP - triangular packed

For level 2 and level 3 BLAS options the options argument is CHARACTER*1 and may be passed as character strings. They mean:

- TRANx
  - **N**o transpose
  - **T**ranspose
  - **C**onjugate transpose (X, X^T, X^H)
- UPLO
  - **U**pper triangular
  - **L**ower triangular
- DIAG
  - **N**on-unit triangular
  - **U**nit triangular
- SIDE
  - **L**eft - A or op(A) on the left
  - **R**ight - A or op(A) on the right

For real matrices, TRANSx=T and TRANSx=C have the same meaning. For Hermitian matrices, TRANSx=T is not allowed. For complex symmetric matrices, TRANSx=H is not allowed.

There were 38 BLAS Level 1 routines defined in [Laws79]. They are

- Dot product SDSDOT, DSDOT, DQ-IDOT DQ-ADOT C-UDOT C-CDOT DDOT SDOT
- Constant times a vector plus a vector CAXPY DAXPY SAXPY
- Set up Givens rotation DROTG SROTG
- Apply rotation DROT SROT
- Set up modified Givens rotation DROTMG SROTMG
- Apply modified rotation DROTM SROTM
- Copy x into y CCOPY DCOPY SCOPY
- Sway x and y CSWAP DSWAP SSWAP
- 2-norm (Euclidean length) SCNRM2 DNRM2 SNRM2
- Sum of absolute values SCASUM DASUM SASUM

- Constant times a vector CSSCAL CSCAL DSCAL SSCAL
- Index of maximum element ICAMAX IDAMAX ISAMAX

where

- I Integer
- S Single Precision
- D Double Precision
- C Single Precision Complex
- Q extended precision
- Z COMPLEX*16

Vector arguments are permitted to have a storage spacing between elements. This spacing is specified by an increment parameter. For example, suppose a vector x having components x_i, $i = 1, ldots, N$ is stored in a DOUBLE PRECISION array DX() with increment parameter INCX. If $INCX \geq 0$ then x_i is stored in $DX(1 + (i - 1) * INCX)$. If $INCX < 0$ then x_i is stored in $DX(1 + (N - 1) * |INCX|)$.

Chapter 4

Optimizations

This code was generated using Raymond Toy's Fortran to Lisp conversion program. Thus the code contains whatever optimizations were in the original Fortran.

That said, we quote from Chellappa, et al. [Chel06]:

> ... the task of achieving the highest performance with an implementation usually lies to a great extent with the programmer. For a given problem, he or she has to carefully consider different algorithms and possibly restructure them to adapt to the given platform's memory hierarchy and available parallelism. This is very difficult, time-consuming, and requires interdisciplinary knowledge about algorithms, software optimizations, and the hardware architecture. Further, the tuning process is platform-dependent: an implementation optimized for one computer will not necessarily be the fastest one on another, since performance depends on many microarchitectural features including but not restricted to the details of the memory hierarchy. Consequently, to achieve highest performance, tuning has to be repeated with the release of each new platform. Since the times of a free speedup (due to frequency scaling) are over, this retuning has become mandatory if any performance gains are desired. Needless to say, the problem is not merely an academic one, but one that affects the software industry as a whole.

The Axiom implementation is intended for prototyping work, not for production code. We maintain compatible API calls so prototype work can be easily ported to native optimized libraries if so desired.

An additional motivation is to research the use of Gustafson's [Gust16] unum ideas, which promises to reduce and/or eliminate overflow and underflow issues.

=====================================================================
BlasLevelOne examples
=====================================================================

The dcabs1 routine computes the sum of the absolute value of the
real and imaginary parts of a complex number.

t1:Complex DoubleFloat := complex(1.0,0)
   1.
```

```
dcabs1(t1)
   1.

t2:Complex DoubleFloat := complex(1.0,1.0)
   1. + %i

dcabs1(t2)
   2.

t3:Complex DoubleFloat := complex(1.0,-1.0)
   1. - %i

dcabs1(t3)
   2.

t4:Complex DoubleFloat := complex(-1.0,-1.0)
   - 1. - %i

dcabs1(t4)
   2.

t5:Complex DoubleFloat := complex(-2.0,-2.0)
   - 2. - 2. %i

dcabs1(t5)
   4.

dnrm2 : (SI, DX, SI) -> DF
  ++ dnrm2 takes the norm of the vector, ||x||
  ++
  ++X a:PRIMARR(DFLOAT):=[[3.0, -4.0, 5.0, -7.0, 9.0]]
  ++X dnrm2(3,a,1) -- 7.0710678118654755 = sqrt(3.0^2 + -4.0^2 + 5.0^2)
  ++X dnrm2(5,a,1) -- 13.416407864998739 = sqrt(180.0)
  ++X dnrm2(3,a,2) -- 10.72380529476361  = sqrt(115.0)

drotg : (DF, DF, DF, DF) -> DX
  ++ drotg computes a 2D plane Givens rotation spanned by two
  ++ coordinate axes.
  ++
  ++X a:MATRIX(DFLOAT):=[[6,5,0],[5,1,4],[0,4,3]]
  ++X drotg(elt(a,1,1),elt(a,1,2),0.0D0,0.0D0)

drot : (SI, DX, SI, DX, SI, DF, DF) -> LDX
  ++ drot computes a 2D plane Givens rotation spanned by two
  ++ coordinate axes. It modifies the arrays in place.
  ++ The call drot(n,dx,incx,dy,incy,c,s) has the dx array which
  ++ contains the y axis locations and dy which contains the
  ++ y axis locations. They are rotated in parallel where
  ++ c is the cosine of the angle and s is the sine of the angle and
  ++ \spad{c^2+s^2 = 1}
  ++
  ++X dx:PRIMARR(DFLOAT):=[[6,0, 1.0, 4.0, -1.0, -1.0]]
  ++X dy:PRIMARR(DFLOAT):=[[5.0, 1.0, -4.0, 4.0, -4.0]]
  ++X drot(5,dx,1,dy,1,0.707106781,0.707106781) -- rotate by 45 degrees
```

```
  ++X dx -- dx has been modified
  ++X dy -- dy has been modified
  ++X drot(5,dx,1,dy,1,0.707106781,-0.707106781) -- rotate by -45 degrees
  ++X dx -- dx has been modified
  ++X dy -- dy has been modified

dscal : (SI, DF, DX, SI) -> DX
  ++ dscal scales each element of the vector by the scalar so
  ++ dscal(n,da,dx,incx) = da*dx for n elements, incremented by incx
  ++ Note that the dx array is modified in place.
  ++
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dscal(6,2.0,dx,1)
  ++X dx
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dscal(3,0.5,dx,1)
  ++X dx

dswap : (SI, DX, SI, DX, SI) -> LDX
  ++ dswap swaps elements from the first vector with the second
  ++ Note that the arrays are modified in place.
  ++
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dy:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dswap(5,dx,1,dy,1)
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dy:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dswap(3,dx,2,dy,2)
  ++X dx:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dy:PRIMARR(DFLOAT):=[[1.0, 2.0, 3.0, 4.0, 5.0, 6.0]]
  ++X dswap(5,dx,1,dy,-1)

dzasum : (SI, PCDF, SI) -> DF
  ++ dzasum takes the sum over all of the array where each
  ++ element of the array sum is the sum of the absolute
  ++ value of the real part and the absolute value of the
  ++ imaginary part of each array element:
  ++   for i in array do sum = sum + (real(a(i)) + imag(a(i)))
  ++
  ++X d:PRIMARR(COMPLEX(DFLOAT)):=[[1.0+2.0*%i,-3.0+4.0*%i,5.0-6.0*%i]]
  ++X dzasum(3,d,1) -- 21.0
  ++X dzasum(3,d,2) -- 14.0
  ++X dzasum(-3,d,1) -- 0.0

dznrm2 : (SI, PCDF, SI) -> DF
  ++ dznrm2 returns the norm of a complex vector. It computes
  ++ sqrt(sum(v*conjugate(v)))
  ++
  ++X a:PRIMARR(COMPLEX(DFLOAT))
  ++X a:=[[3.+4.*%i,-4.+5.*%i,5.+6.*%i,7.-8.*%i,-9.-2.*%i]]
```

```
  ++X dznrm2(5,a,1)   -- should be 18.028

5.2 lsame

The `lsame` function returns t if `ca` and
cb represent the same letter regardless of case.

This has been replaced everywhere with common lisp's char-equal function which compares characters ignoring case. The type (simple-array character (*)) has been replaced everywhere with character.

5.2.1 fortran code

— lsame.f —

```
      LOGICAL          FUNCTION LSAME( CA, CB )
*
*  -- LAPACK auxiliary routine (version 3.0) --
*     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
*     Courant Institute, Argonne National Lab, and Rice University
*     September 30, 1994
*
*     .. Scalar Arguments ..
      CHARACTER          CA, CB
*     ..
*
*  Purpose
*  =======
*
*  LSAME returns .TRUE. if CA is the same letter as CB regardless of
*  case.
*
*  Arguments
*  =========
*
*  CA      (input) CHARACTER*1
*  CB      (input) CHARACTER*1
*          CA and CB specify the single characters to be compared.
*
* =====================================================================
*
*     .. Intrinsic Functions ..
      INTRINSIC          ICHAR
```

```
*     ..
*     .. Local Scalars ..
      INTEGER            INTA, INTB, ZCODE
*     ..
*     .. Executable Statements ..
*
*     Test if the characters are equal
*
      LSAME = CA.EQ.CB
      IF( LSAME )
     $   RETURN
*
*     Now test for equivalence if both characters are alphabetic.
*
      ZCODE = ICHAR( 'Z' )
*
*     Use 'Z' rather than 'A' so that ASCII can be detected on Prime
*     machines, on which ICHAR returns a value with bit 8 set.
*     ICHAR('A') on Prime machines returns 193 which is the same as
*     ICHAR('A') on an EBCDIC machine.
*
      INTA = ICHAR( CA )
      INTB = ICHAR( CB )
*
      IF( ZCODE.EQ.90 .OR. ZCODE.EQ.122 ) THEN
*
*        ASCII is assumed - ZCODE is the ASCII code of either lower or
*        upper case 'Z'.

5.3 xerbla

The `xerbla` routine is an error handler. It is called if an input parameter has an invalid value.

This function has been rewritten everywhere to use the common lisp error function.

5.3.1 fortran code

— xerbla.f —

```
*  ====================================================================
      SUBROUTINE XERBLA( SRNAME, INFO )
*
*  -- LAPACK auxiliary routine (preliminary version) --
*     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
*     Courant Institute, Argonne National Lab, and Rice University
*     February 29, 1992
*
*     .. Scalar Arguments ..
      CHARACTER*6        SRNAME
      INTEGER            INFO
*     ..
*
*  Purpose
*  =======
*
*  XERBLA  is an error handler for the LAPACK routines.
*  It is called by an LAPACK routine if an input parameter has an
*  invalid value.  A message is printed and execution stops.
*
*  Installers may consider modifying the STOP statement in order to
*  call system-specific exception-handling facilities.
*
*  Arguments
*  =========
```

```
*
*  SRNAME  (input) CHARACTER*6
*          The name of the routine which called XERBLA.
*
*  INFO    (input) INTEGER
*          The position of the invalid parameter in the parameter list
*          of the calling routine.
*
*
      WRITE( *, FMT = 9999 )SRNAME, INFO
*
*
* commented out by RLT
*      STOP
*
 9999 FORMAT( ' ** On entry to ', A6, ' parameter number ', I2, ' had ',
     $      'an illegal value' )
*
*     End of XERBLA
*
      END
```

SYNOPSIS
   Functions/Subroutines
```

```
       subroutine saxpy (N, SA, SX, INCX, SY, INCY)
           SAXPY

Function/Subroutine Documentation
   subroutine saxpy (integer N, real SA, real, dimension(*) SX, integer INCX,
       real, dimension(*) SY, integer INCY)
       SAXPY

Purpose:
 SAXPY constant times a vector plus a vector.
 uses unrolled loops for increments equal to one.
```

SYNOPSIS
   Functions/Subroutines
       subroutine scopy (N, SX, INCX, SY, INCY)
           SCOPY

Function/Subroutine Documentation
   subroutine scopy (integer N, real, dimension(*) SX, integer INCX, real,
       dimension(*) SY, integer INCY)
       SCOPY

Purpose:
 SCOPY copies a vector, x, to a vector, y.
 uses unrolled loops for increments equal to 1.
```

SYNOPSIS
   Functions/Subroutines
       real function sdsdot (N, SB, SX, INCX, SY, INCY)
           SDSDOT

Function/Subroutine Documentation
   real function sdsdot (integer N, real SB, real, dimension(*) SX, integer
       INCX, real, dimension(*) SY, integer INCY)
       SDSDOT

Purpose:
 compute the inner product of two vectors
```

———-

6.8.3 fortran code

— sdsdot.f —

```
*  ====================================================================
      REAL FUNCTION SDSDOT(N,SB,SX,INCX,SY,INCY)
*
*  -- Reference BLAS level1 routine (version 3.4.0) --
*  -- Reference BLAS is a software package provided by Univ. of Tennessee,
*  -- Univ. of California Berkeley, Univ. of Colorado Denver and NAG Ltd..--
*     November 2011
*
*     .. Scalar Arguments ..
      REAL SB
      INTEGER INCX,INCY,N
*     ..
*     .. Array Arguments ..
      REAL SX(*),SY(*)
*     ..
*
*  PURPOSE
*  =======
*
*  Compute the inner product of two vectors with extended
*  precision accumulation.
*
*  Returns S.P. result with dot product accumulated in D.P.
*  SDSDOT = SB + sum for I = 0 to N-1 of SX(LX+I*INCX)*SY(LY+I*INCY),
*  where LX = 1 if INCX .GE. 0, else LX = 1+(1-N)*INCX, and LY is
*  defined in a similar way using INCY.
*
```

```
*  ARGUMENTS
*  =========
*
*  N      (input) INTEGER
*         number of elements in input vector(s)
*
*  SB     (input) REAL
*         single precision scalar to be added to inner product
*
*  SX     (input) REAL array, dimension (N)
*         single precision vector with N elements
*
*  INCX   (input) INTEGER
*         storage spacing between elements of SX
*
*  SY     (input) REAL array, dimension (N)
*         single precision vector with N elements
*
*  INCY   (input) INTEGER
*         storage spacing between elements of SY
*
*  SDSDOT (output) REAL
*         single precision dot product (SB if N .LE. 0)

SYNOPSIS
   Functions/Subroutines
       subroutine srotm (N, SX, INCX, SY, INCY, SPARAM)
           SROTM

Function/Subroutine Documentation
   subroutine srotm (integer N, real, dimension(*) SX, integer INCX, real,
       dimension(*) SY, integer INCY, real, dimension(5) SPARAM)
       SROTM

Purpose:
 Apply the modified Givens transformation, H, to the 2 by N matrix
 (SX**T) , where **T indicates transpose. the elements of SX are in
 (SX**T)

 SX(LX+I*INCX), I = 0 TO N-1, where LX = 1 IF INCX .GE. 0, ELSE
 LX = (-INCX)*N, and similarly for sy using LY and INCY.
 with SPARAM(1)=SFLAG, H has one of the following forms..

 SFLAG=-1.E0     SFLAG=0.E0        SFLAG=1.E0     SFLAG=-2.E0

   (SH11  SH12)    (1.E0  SH12)    (SH11  1.E0)    (1.E0  0.E0)
 H=(          )    (          )    (          )    (          )
   (SH21  SH22),   (SH21  1.E0),   (-1.E0 SH22),   (0.E0  1.E0).
```

```
 See SROTMG for a description of data storage in SPARAM.

Parameters:
N
  N is INTEGER
  number of elements in input vector(s)

SX
  SX is REAL array, dimension N
  double precision vector with N elements

INCX
  INCX is INTEGER
  storage spacing between elements of SX

SY
  SY is REAL array, dimension N
  double precision vector with N elements

INCY
  INCY is INTEGER
  storage spacing between elements of SY

SPARAM
  SPARAM is REAL array, dimension 5
    SPARAM(1)=SFLAG
    SPARAM(2)=SH11
    SPARAM(3)=SH21
    SPARAM(4)=SH12
    SPARAM(5)=SH22
```

SYNOPSIS
   Functions/Subroutines
       subroutine srotmg (SD1, SD2, SX1, SY1, SPARAM)
           SROTMG

Function/Subroutine Documentation
   subroutine srotmg (real SD1, real SD2, real SX1, real SY1, real,
       dimension(5) SPARAM)
       SROTMG

Purpose:
 Construct the modified GIVENS transformation matrix H which zeros
 the second component of the 2-vector  (SQRT(SD1)*SX1,SQRT(SD2)*SY2)**T.
 with SPARAM(1)=SFLAG, H has one of the following forms..

  SFLAG=-1.E0     SFLAG=0.E0        SFLAG=1.E0     SFLAG=-2.E0
```

```
    (SH11  SH12)    (1.E0  SH12)    (SH11  1.E0)    (1.E0  0.E0)
  H=(          )    (          )    (          )    (          )
    (SH21  SH22),   (SH21  1.E0),   (-1.E0 SH22),   (0.E0  1.E0).
  locations 2-4 of SPARAM contain SH11,SH21,SH12, AND SH22
  respectively. (values of 1.E0, -1.E0, or 0.E0 implied by the
  value of SPARAM(1) are not stored in sparam.)

  The values of GAMSQ and RGAMSQ set in the data statement may be
  inexact.  This is ok as they are only used for testing the size
  of SD1 and SD2.  All actual scaling of data is done using gam.

Parameters:
 SD1
   SD1 is REAL

 SD2
   SD2 is REAL

 SX1
   SX1 is REAL

 SY1
   SY1 is REAL

 SPARAM
   SPARAM is REAL array, dimension 5
   SPARAM(1)=SFLAG
   SPARAM(2)=SH11
   SPARAM(3)=SH21
   SPARAM(4)=SH12
   SPARAM(5)=SH22
```

SYNOPSIS
   Functions/Subroutines
       subroutine sscal (N, SA, SX, INCX)
```

```
          SSCAL

Function/Subroutine Documentation
   subroutine sscal (integer N, real SA, real, dimension(*) SX, integer INCX)
       SSCAL

Purpose:
 scales a vector by a constant.
 uses unrolled loops for increment equal to 1.
```

Computes doublefloat $asum \leftarrow ||re(x)||_1 + ||im(x)||_1$

Arguments are:
  * n - fixnum
  * dx -array doublefloat
  * incx - fixnum

Return values are:
  * nil
  * nil
  * nil

NAME
       DASUM  -  BLAS level one, sums the absolute values of the elements of a
       double precision vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DASUM ( n, x, incx )
           INTEGER                       n, incx
           DOUBLE PRECISION              x

AXIOM SIGNATURE:
       SI  ==> SingleInteger
       DF  ==> DoubleFloat
       DX  ==> PrimitiveArray(DoubleFloat)

       dasum: (SI, DX, SI) -> DF

DESCRIPTION
       This routine performs the following vector operation:

                           n
               DASUM <-- Sum abs(x(i))
                          i=1

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be summed.
```

```
                if n <= 0, the result will be 0.0
                if n > length(x) then the whole array is summed.

        x       DOUBLE PRECISION. (input)
                Array of dimension (n-1) * abs(incx)+ 1.
                Vector that contains elements to be summed.

        incx    INTEGER. (input)
                Increment between elements of x.
                If incx <= 0, the results will be 0.0

RESULT:
        DASUM   DOUBLE PRECISION. (output)
                Sum of the absolute values of the elements of the vector x.
                If n <= 0, DASUM is set to 0.0

NOTES:
        Axiom uses 0-based arrays. Fortran uses 1-based arrays.

        if the index of the array exceeds the length of x
        then no additional elements are added. Thus,
        if x = #(1.0 2.0 3.0 4.0 5.0 6.0)
        then
         (dasum 3 a -1) =  0.0 ; neg incx
         (dasum 3 a 0)  =  0.0 ; zero incx
         (dasum -1 a 1) =  0.0 ; neg elements
         (dasum 0 a 1)  =  0.0 ; no elements
         (dasum 1 a 1)  =  1.0 ; 1.0
         (dasum 2 a 1)  =  3.0 ; 1.0+2.0
         (dasum 3 a 1)  =  6.0 ; 1.0+2.0+3.0
         (dasum 4 a 1)  = 10.0 ; 1.0+2.0+3.0+4.0
         (dasum 5 a 1)  = 15.0 ; 1.0+2.0+3.0+4.0+5.0
         (dasum 6 a 1)  = 21.0 ; 1.0+2.0+3.0+4.0+5.0+6.0
         (dasum 7 a 1)  = 21.0 ; 1.0+2.0+3.0+4.0+5.0+6.0

7.2.2 Axiom help page

— daxpy.help —

```
=====================================================================
daxpy examples
=====================================================================

For each of the following examples we assume that we have preset
the variables to the following values. Note that the daxpy function
will modify the second array. Each example assumes we have reset
the variables to these values.

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] ]
b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] ]

then we compute the sum of the first 3 elements of each vector
and we show the steps of the computation with trailing comments.
The comments show which elements are changed and what the computation is.

daxpy(3,2.0,a,1,b,1) ==> [3.,6.,9.,4.,5.,6.,7.]
  dy(0)[3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(1)[6.0] = dy(1)[2.0] + ( da[2.0] * dx(1)[2.0] )
  dy(2)[9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )

or we compute the first 7 elements of each vector

daxpy(7,2.0,a,1,b,1) ==> [3.,6.,9.,12.,15.,18.,21.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(1) [6.0] = dy(1)[2.0] + ( da[2.0] * dx(1)[2.0] )
  dy(2) [9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )
  dy(3)[12.0] = dy(3)[4.0] + ( da[2.0] * dx(3)[4.0] )
  dy(4)[15.0] = dy(4)[5.0] + ( da[2.0] * dx(4)[5.0] )
  dy(5)[18.0] = dy(5)[6.0] + ( da[2.0] * dx(5)[6.0] )
  dy(6)[21.0] = dy(6)[7.0] + ( da[2.0] * dx(6)[7.0] )

or we compute the first 8 elements, which fails due to the fact that
the vectors are not long enough.

daxpy(8,2.0,a,1,b,1) ==> [1.,2.,3.,4.,5.,6.,7.]

or we compute the 3 elements, taking every 3rd element, giving the
index of 0, 3, 6

daxpy(3,2.0,a,3,b,3) ==> [3.,2.,3.,12.,5.,6.,21.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(3)[12.0] = dy(3)[4.0] + ( da[2.0] * dx(3)[4.0] )
  dy(6)[21.0] = dy(6)[7.0] + ( da[2.0] * dx(6)[7.0] )

or we compute 4 elements, taking every 2nd element, giving the
index of 0, 2, 4, 6

daxpy(4,2.0,a,2,b,2) ==> [3.,2.,9.,4.,15.,6.,21.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
```

```
  dy(2) [9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )
  dy(4)[15.0] = dy(4)[5.0] + ( da[2.0] * dx(4)[5.0] )
  dy(6)[21.0] = dy(6)[7.0] + ( da[2.0] * dx(6)[7.0] )

or we compute 5 elements, taking every 2nd element, which fails
due to vector length

daxpy(5,2.0,a,2,b,2) ==> [1.,2.,3.,4.,5.,6.,7.]

or we compute 3 elements, taking every 2nd value, giving the
index of 0, 2, 4

daxpy(3,2.0,a,2,b,2) ==> [3.,2.,9.,4.,15.,6.,7.]
  dy(0) [3.0] = dy(0)[1.0] + ( da[2.0] * dx(0)[1.0] )
  dy(2) [9.0] = dy(2)[3.0] + ( da[2.0] * dx(2)[3.0] )
  dy(4)[15.0] = dy(4)[5.0] + ( da[2.0] * dx(4)[5.0] )

or we compute 3 elements, taking every 2nd value, giving the
index of 0, 2, 4 but with a negative multiplier

daxpy(3,-2.0,a,2,b,2) ==> [- 1.,2.,- 3.,4.,- 5.,6.,7.]
  dy(0)[-1.0] = dy(0)[1.0] + ( da[-2.0] * dx(0)[1.0] )
  dy(2)[-3.0] = dy(2)[3.0] + ( da[-2.0] * dx(2)[3.0] )
  dy(4)[-5.0] = dy(4)[5.0] + ( da[-2.0] * dx(4)[5.0] )

or we change the lengths of the input vectors, making them unequal.
So for the next two examples we assume the arrays look like:

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0] ]
b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0] ]

We compute 3 elements, with a negative multiplier, and different increments
using an index for the 'a' array having values 0, 1, 2
using an index for the 'b' array having values 0, 2, 3

daxpy(3,-2.0,a,1,b,2) ==> [- 1.,2.,- 1.,4.,- 1.]
  dy(0)[-1.0] = dy(0)[1.0] + ( da[-2.0] * dx(0)[1.0] )
  dy(2)[-1.0] = dy(2)[3.0] + ( da[-2.0] * dx(1)[2.0] )
  dy(4)[-1.0] = dy(4)[5.0] + ( da[-2.0] * dx(2)[3.0] )

or we compute 3 elements with a multiplier of 0.0 which fails

daxpy(3,0.0,a,1,b,2) ==> [1.,2.,3.,4.,5.,6.,7.]

=====================================================================
Man Page Details
=====================================================================

NAME
       DAXPY - BLAS level one axpy subroutine
```

```
SYNOPSIS
       SUBROUTINE DAXPY    ( n, alpha, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE PRECISION  alpha, x, y

DESCRIPTION
       DAXPY  adds  a  scalar multiple of a double precision vector to another
       double precision vector.

       DAXPY computes a constant alpha times a vector x plus a vector y.   The
       result overwrites the initial values of vector y.

       This routine performs the following vector operation:

            y  <--  alpha*x + y

       incx and incy specify the increment between two consecutive
       elements of respectively vector x and y.

ARGUMENTS
       n       INTEGER. (input)
               Number  of  elements in the vectors.  If n <= 0, these routines
               return without any computation.

       alpha   DOUBLE PRECISION. (input)
               If alpha = 0 this routine returns without any computation.

       x       DOUBLE PRECISION, (input)
               Array of dimension (n-1) * |incx| + 1.  Contains the vector  to
               be scaled before summation.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE PRECISION, (input and output)
               array of dimension (n-1) * |incy| + 1.
               Before calling the routine, y contains the vector to be summed.
               After the routine ends, y contains the result of the summation.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

RETURN VALUES
       When  n <= 0, double precision alpha = 0., this routine returns immedi-
```

```
      ately with no change in its arguments.
```

o )help dcabs1
```

———-

Axiom represents the type Complex(DoubleFloat) as a pair whose car is the real part and whose cdr is the imaginary part. This fact is used in this implementation.

This should really be a macro.

7.4.2 Axiom help page

— dcopy.help —

```
=====================================================================
dcopy examples
=====================================================================

Assume we have two arrays which we initialize to these values:
a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0, 6.0, 7.0] ]

b:PRIMARR(DFLOAT):=[ [ 0.0, 0.0, 0.0, 0.0, 0.0, 0.0, 0.0] ]

Note that after each call to dcopy the b array is modified.
The changed value is shown. We reset it after each bcopy but we
do not show that here.

dcopy(3,a,1,b,1) ==> [1.,2.,3.,0.,0.,0.,0.]

dcopy(7,a,1,b,1) ==> [1.,2.,3.,4.,5.,6.,7.]

dcopy(8,a,1,b,1) ==> [0.,0.,0.,0.,0.,0.,0.]

dcopy(3,a,3,b,3) ==> [1.,0.,0.,4.,0.,0.,7.]

dcopy(4,a,2,b,2) ==> [1.,0.,3.,0.,5.,0.,7.]

dcopy(5,a,2,b,2) ==> [0.,0.,0.,0.,0.,0.,0.]

dcopy(3,a,2,b,2) ==> [1.,0.,3.,0.,5.,0.,0.]

The arrays can be of different lengths:

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0] ]

b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0] ]

dcopy(3,a,1,b,1) ==>  [1.,2.,3.,4.,5.]

dcopy(3,a,1,b,2) ==>  [1.,2.,2.,4.,3.]

a:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0, 4.0, 5.0] ]

b:PRIMARR(DFLOAT):=[ [ 1.0, 2.0, 3.0] ]

dcopy(5,a,1,b,1) ==> [1.,2.,3.]

NAME
```

```
       DCOPY  -  BLAS level one, copies a double precision vector into another
       double precision vector

SYNOPSIS
       SUBROUTINE DCOPY    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE PRECISION  x, y

DESCRIPTION
       DCOPY copies a double precision vector into  another  double  precision
       vector.  DCOPY copies a vector x, whose length is n to a vector y. incx
       and incy specify the increment  between  two  consecutive  elements  of
       respectively vector x and y.

       This routine performs the following vector operation:

            y  <--  x

       where x and y are double precision vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be copied.
               If n <= 0, this routine returns without computation.

       x       DOUBLE PRECISION, (input)
               Vector from which to copy.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the y vector is unchanged

       y       DOUBLE PRECISION, (output)
               array of dimension (n-1) * |incy| + 1, result vector.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the y vector is unchanged

            ------

NAME
       DDOT  -  BLAS  level one, computes a dot product (inner product) of two
       double precision vectors

SYNOPSIS
       DOUBLE PRECISION FUNCTION DDOT ( n, x, incx, y, incy )

           INTEGER                      n, incx, incy

           DOUBLE PRECISION             x, y

DESCRIPTION
       DDOT computes a dot product of two double precision vectors  (1  double
       precision inner product).
         2
```

```
       This routine performs the following vector operation:

                                                  n
               DDOT  <--  (transpose of x) * y  =  Sum  x(i)*y(i)
                                                 i=1
       where x and y are double precision vectors.

       If n <= 0, DDOT is set to 0.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in each vector.

       x       DOUBLE PRECISION. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the first vector operand.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE PRECISION, (input)
               Array of dimension (n-1) * |incy| + 1.
               Array y contains the second vector operand.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

RETURN VALUES
       DDOT    DOUBLE PRECISION. Result (dot product). (output)

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

=====================================================================

NAME
       DNRM2 - BLAS level one, computes the Euclidean norm of a vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DNRM2 ( n, x, incx )

           INTEGER                      n, incx

           DOUBLE PRECISION             x
```

```
DESCRIPTION
       DNRM2  computes the Euclidean (L2) norm of a double precision real vec-
       tor, as follows:

               DNRM2 <-- ||x||
                              2

       where x is a double precision real vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the operand vector.

       x       DOUBLE PRECISION. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the operand vector.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

RETURN VALUES
       DNRM2   DOUBLE PRECISION. Result (Euclidean norm). (output)
               If n <= 0, DNRM2 is set to 0d0.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)
```

=====================================================================

We set up two arrays of doublefloats, dx and dy

dx:PRIMARR(DFLOAT):=[[6,0, 1.0, 4.0, -1.0, -1.0]]

     [6.,0.,1.,4.,- 1.,- 1.]

dy:PRIMARR(DFLOAT):=[[5.0, 1.0, -4.0, 4.0, -4.0]]

     [5.,1.,- 4.,4.,- 4.]

We rotate them by 45 degrees where
   cos(45) = 0.707106781
   sin(45) = 0.707106781

drot(5,dx,1,dy,1,0.707106781,0.707106781) -- rotate by 45 degrees

   [ [7.778174591, 0.70710678100000002, - 2.1213203429999998,
      5.6568542480000001, - 3.5355339050000003, - 1.],

     [- 0.70710678100000002, 0.70710678100000002, - 3.5355339050000003, 0.,
      - 2.1213203429999998] ]

NOTE that the input arguments, dx and dy were modified, per BLAS spec.

[dx,dy]

   [ [7.778174591, 0.70710678100000002, - 2.1213203429999998,
      5.6568542480000001, - 3.5355339050000003, - 1.],

     [- 0.70710678100000002, 0.70710678100000002, - 3.5355339050000003, 0.,
      - 2.1213203429999998] ]
```

```
We rotate them by -45 degrees where
   cos(-45) =  0.707106781
   sin(-45) = -0.707106781

drot(5,dx,1,dy,1,0.707106781,-0.707106781) -- rotate by -45 degrees

   [ [5.9999999968341839, 7.8496237287950521E-17, 0.99999999947236384,

NAME
       DROT - BLAS level one, plane rotation subroutines

SYNOPSIS
       SUBROUTINE DROT    ( n, x, incx, y, incy, c, s )

           INTEGER          n, incx, incy

           DOUBLE PRECISION x, y, c, s

DESCRIPTION
       DROT   applies  a  plane  rotation matrix to a real sequence of ordered
       pairs:

            (x  , y  ), for all i = 1, 2, ..., n.
              i    i

ARGUMENTS
       n       INTEGER. (input)
               Number of ordered pairs (planar points in DROT) to be  rotated.
               If n <= 0, this routine returns without computation.

       x       DOUBLE PRECISION, (input and output)
               Array  of dimension (n-1) * |incx| + 1.  On input, array x con-
               tains the x-coordinate of each planar point to be rotated.   On
               output,  array x contains the x-coordinate of each rotated pla-
               nar point.

       incx    INTEGER. (input)
               Increment between elements of x.  If incx = 0, the results will
               be unpredictable.
```

```
y       DOUBLE PRECISION, (input and output)
        array of dimension (n-1) * |incy| + 1.
        On  input,  array  y  contains  the y-coordinate of each planar
        point to be rotated.  On output, array y contains the y-coordi-
        nate of each rotated planar point.

incy    INTEGER. (input)
        Increment between elements of y.  If incy = 0, the results will
        be unpredictable.

c       DOUBLE PRECISION, Cosine of the angle of rotation.
        (input)

s       DOUBLE PRECISION, Sine of the angle of rotation. (input)

NOTES
       This routine applies the following plane rotation to each pair
       of elements (x , y):
                                i   i
            _      _       _      _     _      _
            | x(i) |  <--  | c   s |  .  | x(i) |
            | y(i) |       |-s   c |     | y(i) |
            -      -       -      -     -      -

            for i = 1,...,n
                                          2    2
       If coefficients c and s satisfy c  + s  = 1.0, the rotation matrix
       is orthogonal, and the transformation is called a Givens plane
       rotation. If c = 1 and s = 0, DROT returns without modifying any
       input parameters.

       To calculate the Givens coefficients c and s from a two-element
       vector to determine the angle of rotation, use SROTG(3S).

       When working backward (incx < 0 or incy < 0), each routine starts
       at the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)

=====================================================================
drotg examples
=====================================================================

A Givens rotation is a rotation in the plane spanned by two
coordinate axes, named after Wallace Givens. [REF-Wiki3]

A Givens rotation is represented by a matrix of the form

               +-                          -+
               | 1  ...  0  ...  0  ...  0 |
               | .   .   .   .   .   .   . |
               | .    .   .    .   .    . |
               | .    .   .    .   .    . |
               | 0  ...  c  ... -s  ...  0 |
               | .   .   .   .   .   .   . |
G(i,j,theta) = | .    .   .    .   .    . |
               | .    .   .    .   .    . |
               | 0  ...  s  ...  c  ...  0 |
               | .   .   .   .   .   .   . |
               | .    .   .    .   .    . |
               | .    .   .    .   .    . |
               | 0  ...  0  ...  0  ...  1 |
               +-                          -+

where c = cos(theta) and s = sin(theta) appear at the intersections
of the ith, jth rows and columns. The non-zero elements of a Givens
matrix are given by:

g   = 1 for k != i,j
 kk
g   = c
 ii
g   = c              (sign of sine switches for j>i)
```

```
 jj
g   = -s
 ji
g   = s  for i > j
 ij
```

The product G(i,j,theta)*x represents the counterclockwise rotation of the vector in the (i,j) plane of theta radians.

The main use of Givens rotations in numerical linear algebra is to introduce zeros in vectors or matrices. This effect can be employed for computing the QR decomposition of a matrix. One advantage over the Householder tranformations is that they can easily be parallelized, and another is that often for very sparse matrices they have a lower operation count.

When a Givens rotation matrix, G(i,k,theta) multiplies another matrix A from the left, GA, only rows i and j of A are affected. Thus we restrict attention to the following problem. Given a and b, find c=cos(theta) and s=sin(theta) such that

```
+-     -+ +- -+   +- -+
| c  -s | | a |   | r |
|       | |   | = |   |
| s   c | | b |   | 0 |
+-     -+ +- -+   +- -+
```

The solution is

```
r = sqrt(a^2+b^2)
c = a/r
s = -b/r
```

However, the computation for r may overflow or underflow. An alternative formulation avoiding this problem [REF-GC96, p5.1.8] is implemented as the hypot function in many programming languages.

As Anderson [REF-And00] discovered in improving LAPACK, a previously overlooked numerical consideration is continuity. To achieve this we require r to be positive.

```
   if (b = 0) then { c = copysign(1,a); s=0; r=abs(a) }
   else if (a = 0) then { c = 0; s = copysign(1,b); r = abs(b) }
   else if (abs(b) > abs(a)) then
     t = a/b
     u = copysign(sqrt(1+t*t),b)
     s = 1/u
     c = s*t
     r = b*u
   else
```

```
     t = b/a
     u = copysign(sqrt(1+t*t),a)
     c = 1/u
     s = c*t
     r = a*u

copysign can be implemented as x*sgn(y) using the sign function.

NAME
       DGROTG - BLAS level one rotation subroutines

SYNOPSIS
       SUBROUTINE DROTG    ( a, b, c, s )

           DOUBLE PRECISION  a, b, c, s

DESCRIPTION
       DROTG  computes  the  elements  of  a Givens plane rotation matrix such
       that:

             _      _     _   _    _   _
             | c  s |     | a |    | r |
             |-s  c | *   | b | =  | 0 |
             _      _     _   _    _   _

       where  r = +- sqrt ( a**2 + b**2 )  and c**2 + s**2 =1.

       The Givens plane rotation can be used to introduce zero elements into
       a matrix selectively.

ARGUMENTS
       a       (input and output) DOUBLE PRECISION

               First vector component.  On input, the first component  of  the
               vector to be rotated.  On output, a is overwritten by r, the
               first component of the vector in the rotated coordinate  system
               where:

               r = sign(sqrt(a**2 + b**2),a), if |a| > |b|

               r = sign(sqrt(a**2 + b**2),b), if |a| <= |b|

       b       (input and output) DOUBLE PRECISION
```

```
            Second vector component.

            On input, the second component of the vector to be rotated.  On
            output, b contains z, where:

                z=s    if  |a| >  |b|
                z=1/c  if  |a| <= |b|  and  c != 0  and r != 0
                z=1    if  |a| <= |b|  and  c  = 0  and r != 0
                z=0    if  r = 0

    c       (output) DOUBLE PRECISION
            Cosine of the angle of rotation:

                 c = a/r  if  r != 0
                 c = 1    if  r  = 0

    s       (output) DOUBLE PRECISION
            Sine of the angle of rotation:

                 s = b/r  if  r != 0
                 s = 0    if  r  = 0

NOTE
    The value of z, returned in b by DROTG, gives a compact  representation
    of  the rotation matrix, which can be used later to reconstruct c and s
    as in the following example:

         IF (B .EQ. 1. ) THEN
             C = 0.
             S = 1.
         ELSEIF( ABS( B) .LT. 1) THEN
             C = SQRT( 1. - B * B)
             S = B
         ELSE
             C = 1. / B
             S = SQRT( 1 - C * C)
         ENDIF
```

———-

Double precision. Computes plane rotation. Arguments are:

- da - double-float
- db - double-float
- c - double-float
- s - double-float

Returns multiple values where:

- 1 da - double-float
- 2 db - double-float
- 3 c - double-float
- 4 s - double-float

SYNOPSIS
   Functions/Subroutines
```

```
       subroutine drotm (N, DX, INCX, DY, INCY, DPARAM)
           DROTM

Function/Subroutine Documentation
   subroutine drotm (integer N, double precision, dimension(*) DX, integer
       INCX, double precision, dimension(*) DY, integer INCY, double
       precision, dimension(5) DPARAM)
       DROTM

Purpose:
   Apply the modified GIVENS transformation, H, to the 2 by N matrix
   (DX**T) , where **T indicates transpose. the elements of DX are in
   (DY**T)

  DX(LX+I*INCX), I = 0 TO N-1, where LX = 1 IF INCX .GE. 0, ELSE
  LX = (-INCX)*N, and similarly for SY using LY and INCY.
  with DPARAM(1)=DFLAG, H has one of the following forms..

  DFLAG=-1.D0     DFLAG=0.D0        DFLAG=1.D0     DFLAG=-2.D0

    (DH11  DH12)    (1.D0  DH12)    (DH11  1.D0)    (1.D0  0.D0)
  H=(          )    (          )    (          )    (          )
    (DH21  DH22),   (DH21  1.D0),   (-1.D0 DH22),   (0.D0  1.D0).
  see DROTMG for a description of data storage in DPARAM.

Parameters:
 N
   N is INTEGER
   number of elements in input vector(s)

 DX
   DX is DOUBLE PRECISION array, dimension N
   double precision vector with N elements

 INCX
   INCX is INTEGER
   storage spacing between elements of DX

 DY
   DY is DOUBLE PRECISION array, dimension N
   double precision vector with N elements

 INCY
   INCY is INTEGER
   storage spacing between elements of DY

 DPARAM
   DPARAM is DOUBLE PRECISION array, dimension 5
     DPARAM(1)=DFLAG
     DPARAM(2)=DH11
```

```
      DPARAM(3)=DH21
      DPARAM(4)=DH12
      DPARAM(5)=DH22
```

SYNOPSIS
   Functions/Subroutines
       subroutine drotmg (DD1, DD2, DX1, DY1, DPARAM)
           DROTMG

Function/Subroutine Documentation
   subroutine drotmg (double precision DD1, double precision DD2, double
       precision DX1, double precision DY1, double precision, dimension(5)
       DPARAM)
       DROTMG

Purpose:
 Construct the modified GIVENS transformation matrix H which zeros
 the second component of the 2-vector  (DSQRT(DD1)*DX1,DSQRT(DD2)*DY2)**T.
 with DPARAM(1)=DFLAG, H has one of the following forms..

  DFLAG=-1.D0     DFLAG=0.D0        DFLAG=1.D0     DFLAG=-2.D0

    (DH11  DH12)    (1.D0  DH12)    (DH11  1.D0)    (1.D0  0.D0)
  H=(          )    (          )    (          )    (          )
    (DH21  DH22),   (DH21  1.D0),   (-1.D0 DH22),   (0.D0  1.D0).
  locations 2-4 of DPARAM contain DH11, DH21, DH12, AND DH22
  respectively. (Values of 1.D0, -1.D0, or 0.D0 implied by the
  value of DPARAM(1) are not stored in dparam.)

  the values of GAMSQ and RGAMSQ set in the data statement may be
  inexact.  this is ok as they are only used for testing the size
  of DD1 and DD2.  All actual scaling of data is done using gam.

Parameters:
  DD1
    DD1 is DOUBLE PRECISION

  DD2
    DD2 is DOUBLE PRECISION

  DX1
    DX1 is DOUBLE PRECISION

  DY1
    DY1 is DOUBLE PRECISION
```

```
 DPARAM
   DPARAM is DOUBLE PRECISION array, dimension 5
     DPARAM(1)=DFLAG
     DPARAM(2)=DH11
     DPARAM(3)=DH21
     DPARAM(4)=DH12
     DPARAM(5)=DH22
```

NAME
       DSCAL - BLAS level one, scales a double precision vector

SYNOPSIS
       SUBROUTINE DSCAL    ( n, alpha, x, incx )

           INTEGER           n, incx

           DOUBLE PRECISION  alpha, x

DESCRIPTION
       DSCAL  scales a double precision vector with a double precision scalar.
       DSCAL scales the vector x of length n and increment incx  by  the  con-
       stant a.
```

```
       This routine performs the following vector operation:

                 x <-- alpha x

       where alpha is a double precisoin scalar, and x is a double precision
       vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the vector.
               If n <= 0, this routine returns without computation.

       alpha   DOUBLE PRECISION scalar alpha. (input)

       x       DOUBLE PRECISION, (input and output)
               Array of dimension (n-1) * |incx| + 1. Vector to be scaled.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       double precision function dsdot (N, SX, INCX, SY, INCY)
           DSDOT

Function/Subroutine Documentation
   double precision function dsdot (integer N, real, dimension(*) SX, integer
       INCX, real, dimension(*) SY, integer INCY)
       DSDOT

Purpose:
  Compute the inner product of two vectors with extended
  precision accumulation and result.

  Returns D.P. dot product accumulated in D.P., for S.P. SX and SY
  DSDOT = sum for I = 0 to N-1 of  SX(LX+I*INCX) * SY(LY+I*INCY),
  where LX = 1 if INCX .GE. 0, else LX = 1+(1-N)*INCX, and LY is
  defined in a similar way using INCY.

Parameters:
 N
   N is INTEGER
   number of elements in input vector(s)

 SX
   SX is REAL array, dimension(N)
   single precision vector with N elements

 INCX
   INCX is INTEGER
```

```
   storage spacing between elements of SX

 SY
   SY is REAL array, dimension(N)
   single precision vector with N elements

 INCY
   INCY is INTEGER
   storage spacing between elements of SY

Returns:

 DSDOT
   DSDOT is DOUBLE PRECISION
   DSDOT  double precision dot product (zero if N.LE.0)
```

NAME
       DSWAP - BLAS level one, Swaps two double precision vectors

SYNOPSIS
       SUBROUTINE DSWAP    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE PRECISION  x, y

DESCRIPTION
       DSWAP  swaps  two double precision vectors, it interchanges n values of
       vector x and vector y.  incx and incy specify the increment between two
       consecutive elements of respectively vector x and y.

       This routine performs the following vector operation:

                 x <-> y

            where x and y are double precision vectors.

ARGUMENTS
       n       INTEGER. (input)
```

```
               Number of vector elements to be swapped.
               If n <= 0, this routine returns without computation.

       x       DOUBLE PRECISION, (input and output)
               Array of dimension (n-1) * |incx| + 1.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE PRECISION, (input and output)
               array of dimension (n-1) * |incy| + 1. Vector to be swapped.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

*
*       code for unequal increments or equal increments not equal
*         to 1
*
         IX = 1
         IY = 1
         IF (INCX.LT.0) IX = (-N+1)*INCX + 1
         IF (INCY.LT.0) IY = (-N+1)*INCY + 1
         DO I = 1,N
            DTEMP = DX(IX)
            DX(IX) = DY(IY)
            DY(IY) = DTEMP
```

```
            IX = IX + INCX
            IY = IY + INCY
         END DO
      END IF
      RETURN
      END
```

There appears to be a bit of confusion using negative increments. The fortran code does not work as I would have guessed. I don't understand what it was intended to do.

7.13.4 fortran unit test

— dswap example —

SYNOPSIS
   Functions/Subroutines
       subroutine dtrsv (UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
           DTRSV

Function/Subroutine Documentation
   subroutine dtrsv (character UPLO, character TRANS, character DIAG, integer
       N, double precision, dimension(lda,*) A, integer LDA, double precision,
       dimension(*) X, integer INCX)
       DTRSV
```

```
Purpose:
 DTRSV  solves one of the systems of equations
               A*x = b,   or   A**T*x = b,
 where b and x are n element vectors and A is an n by n unit, or
 non-unit, upper or lower triangular matrix.

 No test for singularity or near-singularity is included in this
 routine. Such tests must be performed before calling this routine.

Parameters:
 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

     UPLO = 'U' or 'u'   A is an upper triangular matrix.
     UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the equations to be solved as follows:

     TRANS = 'N' or 'n'   A*x = b.
     TRANS = 'T' or 't'   A**T*x = b.
     TRANS = 'C' or 'c'   A**T*x = b.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit triangular as follows:

     DIAG = 'U' or 'u'   A is assumed to be unit triangular.
     DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 A
   A is DOUBLE PRECISION array of DIMENSION ( LDA, n ).

   Before entry with  UPLO = 'U' or 'u', the leading n by n
   upper triangular part of the array A must contain the upper
   triangular matrix and the strictly lower triangular part of
   A is not referenced.

   Before entry with UPLO = 'L' or 'l', the leading n by n
   lower triangular part of the array A must contain the lower
   triangular matrix and the strictly upper triangular part of
```

```
  A is not referenced.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced either, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).

X
  X is DOUBLE PRECISION array of dimension at least
  ( 1 + ( n - 1 )*abs( INCX ) ).

  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

NAME
       DZASUM - BLAS level one, sums the absolute values of the real and imag-
       inary parts of the elements of a double complex vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DZASUM ( n, x, incx )

           INTEGER                     n, incx

           DOUBLE COMPLEX              x

DESCRIPTION
       This routine performs the following vector operation:

                            n
               DZASUM <-- Sum abs( real(x(i)) ) + abs( aimag(x(i)) )
                           i=1

ARGUMENTS
       n       INTEGER. (input)
```

```
               Number of vector elements to be summed.

       x       DOUBLE COMPLEX. (input)
               Array of dimension (n-1) * abs(incx) + 1.
               Vector that contains elements to be summed.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

RETURN VALUES
       DZASUM  DOUBLE PRECISION. (output)
               Sum of the absolute values of the real and imaginary  parts  of
               the elements of the vector x.
               If n <= 0, DZASUM is set to 0.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)
```

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

dznrm2 examples
=====================================================================

dznrm2 computes the complex norm of the input vector.
For each element it computes the sum
    a.i*conjugate(a.i)
for all i. Then it returns the square root of the final sum.

If the count or increment are negative, the result is 0.0

NAME
       DZNRM2 - BLAS level one, computes the Euclidean norm of a vector

SYNOPSIS
       DOUBLE PRECISION FUNCTION DZNRM2 ( n, x, incx )

           INTEGER                        n, incx

           DOUBLE COMPLEX                 x

DESCRIPTION
       DZNRM2  computes  the Euclidean (L2) norm of a double precision complex
       vector:

               DZNRM2 <-- ||x||
                               2

       where x is a double precision complex vector.
```

```
ARGUMENTS
       n       INTEGER (input)
               Number of elements in the operand vector.

       x       DOUBLE COMPLEX (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the operand vector.

       incx    INTEGER (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

RETURN VALUES
       DZNRM2  DOUBLE PRECISION Result (Euclidean norm). (output)
               If n <= 0, DZNRM2 is set to 0d0.

NOTES
       When  working backward (incx < 0), DZNRM2 starts at the end of the vec-
       tor and moves backward, as follows:

               x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)
```

NAME
       ICAMAX - BLAS level one, maximum index function

SYNOPSIS
       INTEGER FUNCTION ICAMAX ( n, x, incx )

           INTEGER               n, incx

           COMPLEX               x

DESCRIPTION
       ICAMAX  searches a complex vector for the first occurrence of the maxi-
       mum absolute value.
```

```
       ICAMAX determines the first index i such that

       |Real(x )|+ |Imag(x ) | = MAX(|Real(x )| + | Imag(x )|): j = 1, ..., n
              i           i                 j             j
               where x  is an element of a complex vector.
                      j

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       COMPLEX. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       ICAMAX  INTEGER. (output)
               Return  the first index of the maximum absolute value of vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0

            ———-

```

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

NOTE: The Axiom internal representation of PRIMARR(COMPLEX(FLOAT)) is an array where each array element AE is

```
AE = (cons (cons (therealpart 0)) (cons (theimagpart 0)))
```

so we need (caar AE) and (cadr AE) to get the real and imag parts.

NOTE: Array indexing in Axiom is 0-based but Fortran is 1-based so the results are displaced by 1.

NAME
       IDAMAX - BLAS level one, maximum index function

SYNOPSIS
       INTEGER FUNCTION IDAMAX ( n, x, incx )

           INTEGER               n, incx

           DOUBLE PRECISION      x

DESCRIPTION
       IDAMAX  searches  a double precision vector for the first occurrence of
       the the maximum absolute value. The vector x has length n and increment
       incx.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       DOUBLE PRECISION. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       IDAMAX  INTEGER. (output)
               Return the first index of the maximum absolute value of  vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0

            _______

SYNOPSIS
       INTEGER FUNCTION ISAMAX ( n, x, incx )

           INTEGER               n, incx

           REAL                  x

DESCRIPTION
       ISAMAX searches a real vector for the first occurrence of the the maxi-
       mum absolute value. The vector x has length n and increment incx.

       ISAMAX returns the first index i such that
               |x | = MAX |x | : j = 1, ..., n
                 i          j
       where x  is an element of a real vector.
              j

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       REAL. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.

RETURN VALUES
       ISAMAX  INTEGER. (output)
               Return  the first index of the maximum absolute value of vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0
```

NAME
       IZAMAX - BLAS level one, maximum index function

SYNOPSIS
       INTEGER FUNCTION IZAMAX ( n, x, incx )

           INTEGER               n, incx

           DOUBLE COMPLEX        x

DESCRIPTION
       IZAMAX searches a double complex vector for the first occurrence of the
       maximum absolute value.

       IZAMAX determines the first index i such that

       |Real(x )|+ |Imag(x ) | = MAX(|Real(x )| + | Imag(x )|): j = 1, ..., n
              i           i                 j             j
               where x  is an element of a double complex vector.
                      j

ARGUMENTS
       n       INTEGER. (input)
               Number of elements to process in the vector to be searched.  If
               n <= 0, these routines return 0.

       x       DOUBLE COMPLEX. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the vector to be searched.

       incx    INTEGER. (input)
               Increment between elements of x.
```

```
RETURN VALUES
       IZAMAX  INTEGER. (output)
               Return  the first index of the maximum absolute value of vector
               x.  The vector x has length n and increment incx.

NOTES
       When working backward (incx < 0), each routine starts at the end of the
       vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

       The largest absolute value is:

            ABS (x(1+(index-1) * incx)) when incx > 0

            ABS (x(1+(n-index) * |incx|)) when incx < 0

Spad represents complex numbers as a pair where the car is the real part and the cons is the imaginary part. BLAS wants a complex number in fortran format. So we have a design choice to make. Either we could write all of the BLAS code using Spad internal representation or we could follow the BLAS code standard. I've decided to follow the BLAS code standard so we need to create thunks to do the data translation.

NOTE: The Axiom internal representation of PRIMARR(COMPLEX(DFLOAT)) is an array where each array element AE is

```
AE = (cons (therealpart 0)) (cons (theimagpart 0))
```

so we need (car AE) and (cdr AE) to get the real and imag parts.

NOTE: Array indexing in Axiom is 0-based but Fortran is 1-based so the results are displaced by 1.

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine csrot (N, CX, INCX, CY, INCY, C, S)
           CSROT

Function/Subroutine Documentation
   subroutine csrot (integer N, complex, dimension( * ) CX, integer INCX,
       complex, dimension( * ) CY, integer INCY, real C, real S)
       CSROT

Purpose:
 CSROT applies a plane rotation, where the cos and sin (c and s) are real
 and the vectors cx and cy are complex.

Parameters:
 N
   N is INTEGER
   On entry, N specifies the order of the vectors cx and cy.
   N must be at least zero.

 CX
   CX is COMPLEX array, dimension at least ( 1 + ( N - 1 )*abs( INCX ) ).
   Before entry, the incremented array CX must contain the n
   element vector cx. On exit, CX is overwritten by the updated vector cx.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of
   CX. INCX must not be zero.

 CY
   CY is COMPLEX array, dimension at least ( 1 + ( N - 1 )*abs( INCY ) ).
   Before entry, the incremented array CY must contain the n
   element vector cy. On exit, CY is overwritten by the updated vector cy.

 INCY
   INCY is INTEGER
   On entry, INCY specifies the increment for the elements of
   CY. INCY must not be zero.

 C
   C is REAL
   On entry, C specifies the cosine, cos.

 S
   S is REAL
```

```
On entry, S specifies the sine, sin.
```

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cswap (N, CX, INCX, CY, INCY)
           CSWAP

Function/Subroutine Documentation
   subroutine cswap (integer N, complex, dimension(*) CX, integer INCX,
       complex, dimension(*) CY, integer INCY)
       CSWAP

Purpose:
 CSWAP interchanges two vectors.
```

NAME
       ZAXPY - BLAS level one axpy subroutine

SYNOPSIS
       SUBROUTINE ZAXPY    ( n, alpha, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE COMPLEX    alpha, x, y
```

```
DESCRIPTION
       ZAXPY adds a scalar multiple of a double complex vector to another dou-
       ble complex vector.

       ZAXPY computes a constant alpha times a vector x plus a vector y.   The
       result overwrites the initial values of vector y.

       This routine performs the following vector operation:

            y  <--  alpha*x + y

       incx and incy specify the increment between two consecutive
       elements of respectively vector x and y.

ARGUMENTS
       n       INTEGER. (input)
               Number  of  elements in the vectors.  If n <= 0, these routines
               return without any computation.

       alpha   DOUBLE COMPLEX. (input)
               If alpha = 0 this routine returns without any computation.

       x       DOUBLE COMPLEX. (input)
               Array of dimension (n-1) * |incx| + 1.  Contains the vector  to
               be scaled before summation.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE COMPLEX. (input and output)
               array of dimension (n-1) * |incy| + 1.
               Before calling the routine, y contains the vector to be summed.
               After the routine ends, y contains the result of the summation.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

NOTES
       This  routine  is  Level  1  Basic  Linear Algebra Subprograms (Level 1
       BLAS).

       When working backward (incx < 0 or incy < 0), each  routine  starts  at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

```
RETURN VALUES
       When  n  <=  0, double complex alpha = 0 = 0.+0.i, this routine returns
       immediately with no change in its arguments.
```

———-

Computes (complex double-float) $y \leftarrow \alpha x + y$

Arguments are:

- n - fixnum
- da - (complex double-float)
- dx - array (complex double-float)
- incx - fixnum
- dy - array (complex double-float)
- incy - fixnum

```

Axiom delivers PRIMARR(COMPLEX(DFLOAT)) as a list of pairs. We create a thunk function zaxpySpad which creates an array of complex double-float objects required by zaxpy.

The zaxpy function is defined to modify the second array. So the thunk function has to setf this information back into the original array.

The zaxpySpad function could be more efficient if it only copied elements that were modified. This was not done because of the overhead of figuring out which elements this could be under all possible arguments.

NAME
       ZCOPY  -  BLAS  level  one, copies a double complex vector into another
       double complex vector

SYNOPSIS
       SUBROUTINE ZCOPY    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE COMPLEX    x, y

DESCRIPTION
       ZCOPY copies a double complex vector into another double  complex  vec-
       tor.   ZCOPY  copies  a vector x, whose length is n to a vector y. incx
       and incy specify the increment  between  two  consecutive  elements  of
```

```
       respectively vector x and y.

       This routine performs the following vector operation:

            y  <--  x

       where x and y are double complex vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be copied.
               If n <= 0, this routine returns without computation.

       x       DOUBLE COMPLEX, (input)
               Vector from which to copy.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE COMPLEX, (output)
               array of dimension (n-1) * |incy| + 1, result vector.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

NAME
       ZDOTC  - BLAS level one, computes the hermitian dot product of
       vector x and vector y.

SYNOPSIS
       DOUBLE COMPLEX FUNCTION ZDOTC ( n, x, incx, y, incy )

           INTEGER                     n, incx, incy

           COMPLEX*16                  x, y

DESCRIPTION
       ZDOTC computes a dot product of the conjugate of a complex  vector
       and another complex vector (complex inner product).

       ZDOTC computes a dot product of the conjugate of a complex vector
       and another complex vector (complex inner product).

       This routine performs the following vector operation:

            ZDOTC  <--  (conjugate transpose of x) * y
                            n
                        =  Sum  (complex conjugate of x(i))*y(i)
```

```
                        i=1
                                                H
       where x and y are complex vectors, and x is the conjugate
       transpose of x.

       If n <= 0, ZDOTC is set to 0.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in each vector.

       x       COMPLEX*16. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the first vector operand.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       COMPLEX*16. (input)
               Array of dimension (n-1) * |incy| + 1.
               Array y contains the second vector operand.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

RETURN VALUES
       ZDOTC    DOUBLE COMPLEX. Result (dot product). (output)

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine
       starts at the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)

NAME
       ZDOTU - BLAS level one, computes computes a dot product (inner product)
       of two complex vectors

SYNOPSIS
       DOUBLE COMPLEX FUNCTION ZDOTU ( n, x, incx, y, incy )

           INTEGER                     n, incx, incy

           COMPLEX*16                  x, y

DESCRIPTION
       ZDOTU computes a dot product of two complex vectors.

       This routine performs the following vector operation:

                                                   n
               ZDOTU  <--  (transpose of x) * y  =  Sum  x(i)*y(i)
                                                   i=1
                                          T
       where x and y are real vectors, and x is the transpose of
       x.

       If n <= 0, ZDOTU is set to 0.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in each vector.

       x       COMPLEX*16. (input)
               Array of dimension (n-1) * |incx| + 1.
               Array x contains the first vector operand.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       COMPLEX*16. (input)
               Array of dimension (n-1) * |incy| + 1.
               Array y contains the second vector operand.

       incy    INTEGER. (input)
               Increment between elements of y.
               If incy = 0, the results will be unpredictable.

RETURN VALUES
       ZDOTU   DOUBLE COMPLEX. Result (dot product). (output)

NOTES
```

```
When  working  backward  (incx < 0 or incy < 0), each routine starts at
the end of the vector and moves backward, as follows:

     x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

     y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)
```

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zdrot (N, CX, INCX, CY, INCY, C, S)
           ZDROT

Function/Subroutine Documentation
   subroutine zdrot (integer N, complex*16, dimension( * ) CX, integer INCX,
       complex*16, dimension( * ) CY, integer INCY, double precision C, double
       precision S)
       ZDROT

Purpose:
 Applies a plane rotation, where the cos and sin (c and s) are real
 and the vectors cx and cy are complex.

Parameters:
 N
   N is INTEGER
   On entry, N specifies the order of the vectors cx and cy.
   N must be at least zero.

 CX
   CX is COMPLEX*16 array, dimension at least ( 1 + ( N - 1 )*abs( INCX ) ).
   Before entry, the incremented array CX must contain the n
   element vector cx. On exit, CX is overwritten by the updated vector cx.

 INCX
   INCX is INTEGER
     On entry, INCX specifies the increment for the elements of CX.
     INCX must not be zero.

 CY
   CY is COMPLEX*16 array, dimension at least ( 1 + ( N - 1 )*abs( INCY ) ).
   Before entry, the incremented array CY must contain the n
   element vector cy. On exit, CY is overwritten by the updated vector cy.

 INCY
```

```
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of CY.
  INCY must not be zero.

C
  C is DOUBLE PRECISION
  On entry, C specifies the cosine, cos.

S
  S is DOUBLE PRECISION
  On entry, S specifies the sine, sin.
```

NAME
       ZDSCAL - BLAS level one, Scales a double complex vector

SYNOPSIS
       SUBROUTINE ZDSCAL    ( n, alpha, x, incx )

           INTEGER            n, incx

           DOUBLE COMPLEX     x

           DOUBLE PRECISION   alpha

DESCRIPTION
       ZDSCAL  scales  a double complex vector with a double precision scalar.
       ZDSCAL scales the vector x of length n and increment incx by  the  con-
```

```
       stant alpha.

       This routine performs the following vector operation:

                 x <-- alpha x

       where alpha is a double precision scalar, and x is a double complex
       vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the vector.
               If n <= 0, this routine returns without computation.

       alpha   DOUBLE PRECISION. (input)
               Value used to scale vector

       x       DOUBLE COMPLEX. (input and output)
               Array  of dimension (n-1) * abs(incx) + 1. Vector to be scaled.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

NAME
       ZROTG - Extensions to BLAS level one rotation subroutines

SYNOPSIS
           SUBROUTINE ZROTG ( a, b, c, s )

           DOUBLE COMPLEX
                        a, b, s

           DOUBLE PRECISION
                        c

DESCRIPTION
       ZROTG  computes  the  elements  of  a Givens plane rotation matrix such
       that:

            -            -    -   -    -   -
            |      c    s |    | a |    | r |
            |-congj(s)  c | *  | b | =  | 0 |
            -            -    -   -    -   -

       where r = (a / sqrt(conjg(a)*a)) * sqrt ( conjg(a)*a + conjg(b)*b ) ,
       and the notation conjg(z) represents the complex conjugate of z.

       The Givens plane rotation can be used to introduce zero elements into
       a matrix selectively.

ARGUMENTS
       a       (input and output) DOUBLE COMPLEX

               First vector component.

               On input, the first component of the vector to be rotated.   On
               output,  a is overwritten by the unique complex number r, whose
               size in the complex plane is the Euclidean norm of the  complex
               vector  (a,b),  and whose direction in the complex plane is the
               same as that of the original complex element a.

                   if |a| != 0
```

```
            r = a / |a| * sqrt( conjg(a)*a + conjg(b)*b )

            if |a| = 0
            r = b

b       (input) DOUBLE COMPLEX

        Second vector component.

        The second component of the vector to be rotated.

c       (output) DOUBLE PRECISION

        Cosine of the angle of rotation.

            if |a| != 0
            c = |a| /  sqrt( conjg(a)*a + conjg(b)*b )

            if |a| = 0
            c = 0

s       (output) DOUBLE COMPLEX
        Sine of the angle of rotation.

            if |a| != 0
            c=a/|a|*conjg(b)/sqrt(conjg(a)*a+conjg(b)*b)

            if |a| = 0
            s = ( 1.0 , 0.0 )
```

———-

(Complex Double-Float). Computes plane rotation. Arguments are:

- da - (complex double-float)
- db - (complex double-float)
- c - double-float
- s - (complex double-float)

Returns multiple values where:

- 1 da - ca
- 2 db - nil

- 3 c - c
- 4 s - s

NAME
       ZSCAL - BLAS level one, Scales a double complex vector

SYNOPSIS
       SUBROUTINE ZSCAL    ( n, alpha, x, incx )

           INTEGER            n, incx

           DOUBLE COMPLEX     x, alpha

DESCRIPTION
       ZSCAL  scales  a  double  complex  vector with a double complex scalar.
       ZSCAL scales the vector x of length n and increment incx  by  the  con-
       stant alpha.

       This routine performs the following vector operation:

                 x <-- alpha x

       where alpha is a double complex scalar, and x is a double complex
       vector.

ARGUMENTS
       n       INTEGER. (input)
               Number of elements in the vector.
               If n <= 0, this routine returns without computation.
```

```
       alpha   DOUBLE COMPLEX. (input)
               Value used to scale vector

       x       DOUBLE COMPLEX. (input and output)
               Array  of dimension (n-1) * abs(incx) + 1. Vector to be scaled.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

NAME
       ZSWAP - BLAS level one, Swaps two double complex vectors

SYNOPSIS
       SUBROUTINE ZSWAP    ( n, x, incx, y, incy )

           INTEGER           n, incx, incy

           DOUBLE COMPLEX    x, y
```

```
DESCRIPTION
       ZSWAP  swaps  two  double  complex vectors, it interchanges n values of
       vector x and vector y.  incx and incy specify the increment between two
       consecutive elements of respectively vector x and y.

       This routine performs the following vector operation:

                 x <-> y

            where x and y are double complex vectors.

ARGUMENTS
       n       INTEGER. (input)
               Number of vector elements to be swapped.
               If n <= 0, this routine returns without computation.

       x       DOUBLE COMPLEX, (input and output)
               Array of dimension (n-1) * |incx| + 1.

       incx    INTEGER. (input)
               Increment between elements of x.
               If incx = 0, the results will be unpredictable.

       y       DOUBLE COMPLEX, (input and output)
               array of dimension (n-1) * |incy| + 1. Vector to be swapped.

       incy    INTEGER. (input)
               Increment between elements of y.  If incy = 0, the results will
               be unpredictable.

NOTES
       When  working  backward  (incx < 0 or incy < 0), each routine starts at
       the end of the vector and moves backward, as follows:

            x(1-incx * (n-1)), x(1-incx * (n-2)), ..., x(1)

            y(1-incy * (n-1)), y(1-incy * (n-2)), ..., y(1)

SYNOPSIS
   Functions/Subroutines
       subroutine sgbmv (TRANS, M, N, KL, KU, ALPHA, A, LDA, X, INCX, BETA, Y,
           INCY)
           SGBMV

Function/Subroutine Documentation
   subroutine sgbmv (character TRANS, integer M, integer N, integer KL,
       integer KU, real ALPHA, real, dimension(lda,*) A, integer LDA, real,
       dimension(*) X, integer INCX, real BETA, real, dimension(*) Y, integer
       INCY)
       SGBMV

Purpose:
 SGBMV  performs one of the matrix-vector operations

 y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,

 where alpha and beta are scalars, x and y are vectors and A is an
 m by n band matrix, with kl sub-diagonals and ku super-diagonals.

 Parameters:
  TRANS
    TRANS is CHARACTER*1
    On entry, TRANS specifies the operation to be performed as follows:

    TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

    TRANS = 'T' or 't'   y := alpha*A**T*x + beta*y.

    TRANS = 'C' or 'c'   y := alpha*A**T*x + beta*y.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.

 KL
   KL is INTEGER
   On entry, KL specifies the number of sub-diagonals of the
```

```
  matrix A. KL must satisfy  0 .le. KL.

KU
  KU is INTEGER
  On entry, KU specifies the number of super-diagonals of the
  matrix A. KU must satisfy  0 .le. KU.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.

A
  A is REAL array of DIMENSION ( LDA, n ).
  Before entry, the leading ( kl + ku + 1 ) by n part of the
  array A must contain the matrix of coefficients, supplied
  column by column, with the leading diagonal of the matrix in
  row ( ku + 1 ) of the array, the first super-diagonal
  starting at position 2 in row ku, the first sub-diagonal
  starting at position 1 in row ( ku + 2 ), and so on.
  Elements in the array A that do not correspond to elements
  in the band matrix (such as the top left ku by ku triangle)
  are not referenced.

  The following program segment will transfer a band matrix
  from conventional full matrix storage to band storage:

       DO 20, J = 1, N
          K = KU + 1 - J
          DO 10, I = MAX( 1, J - KU ), MIN( M, J + KL )
             A( K + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( kl + ku + 1 ).

X
  X is REAL array of DIMENSION at least
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

```
BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

Y
  Y is REAL array of DIMENSION at least
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry, the incremented array Y must contain the
  vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine sgemv (TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           SGEMV

Function/Subroutine Documentation
   subroutine sgemv (character TRANS, integer M, integer N, real ALPHA, real,
       dimension(lda,*) A, integer LDA, real, dimension(*) X, integer INCX,
       real BETA, real, dimension(*) Y, integer INCY)
       SGEMV

Purpose:
  SGEMV  performs one of the matrix-vector operations

  y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,

  where alpha and beta are scalars, x and y are vectors and A is an
  m by n matrix.

Parameters:
  TRANS
    TRANS is CHARACTER*1
    On entry, TRANS specifies the operation to be performed as follows:

    TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

    TRANS = 'T' or 't'   y := alpha*A**T*x + beta*y.

    TRANS = 'C' or 'c'   y := alpha*A**T*x + beta*y.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 A
   A is REAL array of DIMENSION ( LDA, n ).
   Before entry, the leading m by n part of the array A must
   contain the matrix of coefficients.

 LDA
   LDA is INTEGER
```

```
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, m ).

X
  X is REAL array of DIMENSION at least
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

Y
  Y is REAL array of DIMENSION at least
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine sger (M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
           SGER

Function/Subroutine Documentation
   subroutine sger (integer M, integer N, real ALPHA, real, dimension(*) X,
       integer INCX, real, dimension(*) Y, integer INCY, real,
       dimension(lda,*) A, integer LDA)
       SGER

Purpose:

 SGER   performs the rank 1 operation A := alpha*x*y**T + A,
        where alpha is a scalar, x is an m element vector, y is an n element
        vector and A is an m by n matrix.

Parameters:

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 X
   X is REAL array of dimension at least ( 1 + ( m - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the m
   element vector x.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

 Y
   Y is REAL array of dimension at least
   ( 1 + ( n - 1 )*abs( INCY ) ).
   Before entry, the incremented array Y must contain the n
   element vector y.

 INCY
```

```
   INCY is INTEGER
   On entry, INCY specifies the increment for the elements of Y.
   INCY must not be zero.

 A
   A is REAL array of DIMENSION ( LDA, n ).
   Before entry, the leading m by n part of the array A must
   contain the matrix of coefficients. On exit, A is
   overwritten by the updated matrix.

 LDA
   LDA is INTEGER
   On entry, LDA specifies the first dimension of A as declared
   in the calling (sub) program. LDA must be at least max( 1, m ).
```

NAME
       ssbmv.f -

SYNOPSIS
   Functions/Subroutines
       subroutine ssbmv (UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           SSBMV

Function/Subroutine Documentation
   subroutine ssbmv (character UPLO, integer N, integer K, real ALPHA, real,
       dimension(lda,*) A, integer LDA, real, dimension(*) X, integer INCX,
       real BETA, real, dimension(*) Y, integer INCY)
       SSBMV

Purpose:
  SSBMV  performs the matrix-vector  operation

    y := alpha*A*x + beta*y,

 where alpha and beta are scalars, x and y are n element vectors and
 A is an n by n symmetric band matrix, with k super-diagonals.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the band matrix A is being supplied as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is being supplied.

   UPLO = 'L' or 'l'   The lower triangular part of A is being supplied.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.
```

```
K
  K is INTEGER
  On entry, K specifies the number of super-diagonals of the
  matrix A. K must satisfy  0 .le. K.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.

A
  A is REAL array of DIMENSION ( LDA, n ).
  Before entry with UPLO = 'U' or 'u', the leading ( k + 1 )
  by n part of the array A must contain the upper triangular
  band part of the symmetric matrix, supplied column by
  column, with the leading diagonal of the matrix in row
  ( k + 1 ) of the array, the first super-diagonal starting at
  position 2 in row k, and so on. The top left k by k triangle
  of the array A is not referenced.

  The following program segment will transfer the upper
  triangular part of a symmetric band matrix from conventional
  full matrix storage to band storage:

       DO 20, J = 1, N
          M = K + 1 - J
          DO 10, I = MAX( 1, J - K ), J
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Before entry with UPLO = 'L' or 'l', the leading ( k + 1 )
  by n part of the array A must contain the lower triangular
  band part of the symmetric matrix, supplied column by
  column, with the leading diagonal of the matrix in row 1 of
  the array, the first sub-diagonal starting at position 1 in
  row 2, and so on. The bottom right k by k triangle of the
  array A is not referenced.

  The following program segment will transfer the lower
  triangular part of a symmetric band matrix from conventional
  full matrix storage to band storage:

       DO 20, J = 1, N
          M = 1 - J
          DO 10, I = J, MIN( N, J + K )
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE
```

```
LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( k + 1 ).

X
  X is REAL array of DIMENSION at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta.

Y
  Y is REAL array of DIMENSION at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the
  vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine sspmv (UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
           SSPMV

Function/Subroutine Documentation
   subroutine sspmv (character UPLO, integer N, real ALPHA, real, dimension(*)
       AP, real, dimension(*) X, integer INCX, real BETA, real, dimension(*)
       Y, integer INCY)
       SSPMV

Purpose:
  SSPMV  performs the matrix-vector operation

  y := alpha*A*x + beta*y,

  where alpha and beta are scalars, x and y are n element vectors and
  A is an n by n symmetric matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the matrix A is supplied in the packed
   array AP as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is supplied in AP.

   UPLO = 'L' or 'l'   The lower triangular part of A is supplied in AP.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 AP
   AP is REAL array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

   Before entry with UPLO = 'U' or 'u', the array AP must
   contain the upper triangular part of the symmetric matrix
   packed sequentially, column by column, so that AP( 1 )
   contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 1, 2 )
   and a( 2, 2 ) respectively, and so on.
   Before entry with UPLO = 'L' or 'l', the array AP must
   contain the lower triangular part of the symmetric matrix
```

```
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 )
  and a( 3, 1 ) respectively, and so on.

X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

Y
  Y is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

The vector and matrix arguments are not referenced when N = 0, or M = 0

SYNOPSIS
   Functions/Subroutines
       subroutine sspr (UPLO, N, ALPHA, X, INCX, AP)
           SSPR

Function/Subroutine Documentation
   subroutine sspr (character UPLO, integer N, real ALPHA, real, dimension(*)
       X, integer INCX, real, dimension(*) AP)
       SSPR

Purpose:
  SSPR    performs the symmetric rank 1 operation

    A := alpha*x*x**T + A,

  where alpha is a real scalar, x is an n element vector and A is an
```

```
  n by n symmetric matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the matrix A is supplied in the packed
   array AP as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is supplied in AP.

   UPLO = 'L' or 'l'   The lower triangular part of A is supplied in AP.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 X
   X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the n
   element vector x.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

 AP
   AP is REAL array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

   Before entry with  UPLO = 'U' or 'u', the array AP must
   contain the upper triangular part of the symmetric matrix
   packed sequentially, column by column, so that AP( 1 )
   contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 1, 2 )
   and a( 2, 2 ) respectively, and so on. On exit, the array
   AP is overwritten by the upper triangular part of the
   updated matrix.

   Before entry with UPLO = 'L' or 'l', the array AP must
   contain the lower triangular part of the symmetric matrix
   packed sequentially, column by column, so that AP( 1 )
   contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 )
   and a( 3, 1 ) respectively, and so on. On exit, the array
   AP is overwritten by the lower triangular part of the
```

updated matrix.

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine sspr2 (UPLO, N, ALPHA, X, INCX, Y, INCY, AP)
           SSPR2

Function/Subroutine Documentation
   subroutine sspr2 (character UPLO, integer N, real ALPHA, real, dimension(*)
       X, integer INCX, real, dimension(*) Y, integer INCY, real, dimension(*)
       AP)
       SSPR2

Purpose:
 SSPR2  performs the symmetric rank 2 operation

    A := alpha*x*y**T + alpha*y*x**T + A,

 where alpha is a scalar, x and y are n element vectors and A is an
 n by n symmetric matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the matrix A is supplied in the packed
   array AP as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is supplied in AP.

   UPLO = 'L' or 'l'   The lower triangular part of A is supplied in AP.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 X
   X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the n
   element vector x.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

 Y
```

```
  Y is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

AP
  AP is REAL array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

  Before entry with  UPLO = 'U' or 'u', the array AP must
  contain the upper triangular part of the symmetric matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 1, 2 )
  and a( 2, 2 ) respectively, and so on. On exit, the array
  AP is overwritten by the upper triangular part of the
  updated matrix.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular part of the symmetric matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 )
  and a( 3, 1 ) respectively, and so on. On exit, the array
  AP is overwritten by the lower triangular part of the
  updated matrix.

NAME
       ssymv.f -

SYNOPSIS
   Functions/Subroutines
       subroutine ssymv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           SSYMV

Function/Subroutine Documentation
```

```
   subroutine ssymv (character UPLO, integer N, real ALPHA, real,
       dimension(lda,*) A, integer LDA, real, dimension(*) X, integer INCX,
       real BETA, real, dimension(*) Y, integer INCY)
       SSYMV

Purpose:
   SSYMV  performs the matrix-vector  operation

       y := alpha*A*x + beta*y,

   where alpha and beta are scalars, x and y are n element vectors and
   A is an n by n symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A
   is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of A
   is to be referenced.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 A
   A is REAL array of DIMENSION ( LDA, n ).

   Before entry with  UPLO = 'U' or 'u', the leading n by n
   upper triangular part of the array A must contain the upper
   triangular part of the symmetric matrix and the strictly
   lower triangular part of A is not referenced.
   Before entry with UPLO = 'L' or 'l', the leading n by n
   lower triangular part of the array A must contain the lower
   triangular part of the symmetric matrix and the strictly
   upper triangular part of A is not referenced.

 LDA
   LDA is INTEGER
   On entry, LDA specifies the first dimension of A as declared
```

```
  in the calling (sub) program. LDA must be at least max( 1, n ).

 X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

 INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

 BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

 Y
  Y is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y. On exit, Y is overwritten by the updated vector y.

 INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyr (UPLO, N, ALPHA, X, INCX, A, LDA)
           SSYR

Function/Subroutine Documentation
   subroutine ssyr (character UPLO, integer N, real ALPHA, real, dimension(*)
       X, integer INCX, real, dimension(lda,*) A, integer LDA)
       SSYR

Purpose:
  SSYR   performs the symmetric rank 1 operation

    A := alpha*x*x**T + A,

   where alpha is a real scalar, x is an n element vector and A is an
   n by n symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A
   is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of A
   is to be referenced.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 X
   X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the n
   element vector x.
```

```
INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

A
A is REAL array of DIMENSION ( LDA, n ).

  Before entry with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the symmetric matrix and the strictly
  lower triangular part of A is not referenced. On exit, the
  upper triangular part of the array A is overwritten by the
  upper triangular part of the updated matrix.

  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the symmetric matrix and the strictly
  upper triangular part of A is not referenced. On exit, the
  lower triangular part of the array A is overwritten by the
  lower triangular part of the updated matrix.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyr2 (UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
           SSYR2

Function/Subroutine Documentation
   subroutine ssyr2 (character UPLO, integer N, real ALPHA, real, dimension(*)
       X, integer INCX, real, dimension(*) Y, integer INCY, real,
       dimension(lda,*) A, integer LDA)
       SSYR2

Purpose:
   SSYR2  performs the symmetric rank 2 operation

      A := alpha*x*y**T + alpha*y*x**T + A,

   where alpha is a scalar, x and y are n element vectors and A is an n
   by n symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A
   is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of A
   is to be referenced.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 X
```

```
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

Y
  Y is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

A
  A is REAL array of DIMENSION ( LDA, n ).

  Before entry with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the symmetric matrix and the strictly
  lower triangular part of A is not referenced. On exit, the
  upper triangular part of the array A is overwritten by the
  upper triangular part of the updated matrix.

  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the symmetric matrix and the strictly
  upper triangular part of A is not referenced. On exit, the
  lower triangular part of the array A is overwritten by the
  lower triangular part of the updated matrix.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine stbmv (UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
           STBMV

Function/Subroutine Documentation
   subroutine stbmv (character UPLO, character TRANS, character DIAG, integer
       N, integer K, real, dimension(lda,*) A, integer LDA, real, dimension(*)
       X, integer INCX)
       STBMV

Purpose:
```

```
   STBMV  performs one of the matrix-vector operations

      x := A*x,   or   x := A**T*x,

   where x is an n element vector and  A is an n by n unit, or non-unit,
   upper or lower triangular band matrix, with ( k + 1 ) diagonals.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   x := A*x.

   TRANS = 'T' or 't'   x := A**T*x.

   TRANS = 'C' or 'c'   x := A**T*x.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 K
   K is INTEGER
   On entry with UPLO = 'U' or 'u', K specifies the number of
   super-diagonals of the matrix A.
   On entry with UPLO = 'L' or 'l', K specifies the number of
   sub-diagonals of the matrix A.
   K must satisfy  0 .le. K.
```

```
A
  A is REAL array of DIMENSION ( LDA, n ).

  Before entry with UPLO = 'U' or 'u', the leading ( k + 1 )
  by n part of the array A must contain the upper triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row
  ( k + 1 ) of the array, the first super-diagonal starting at
  position 2 in row k, and so on. The top left k by k triangle
  of the array A is not referenced.

  The following program segment will transfer an upper
  triangular band matrix from conventional full matrix storage
  to band storage:

       DO 20, J = 1, N
          M = K + 1 - J
          DO 10, I = MAX( 1, J - K ), J
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Before entry with UPLO = 'L' or 'l', the leading ( k + 1 )
  by n part of the array A must contain the lower triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row 1 of
  the array, the first sub-diagonal starting at position 1 in
  row 2, and so on. The bottom right k by k triangle of the
  array A is not referenced.

  The following program segment will transfer a lower
  triangular band matrix from conventional full matrix storage
  to band storage:

       DO 20, J = 1, N
          M = 1 - J
          DO 10, I = J, MIN( N, J + K )
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Note that when DIAG = 'U' or 'u' the elements of the array A
  corresponding to the diagonal elements of the matrix are not
  referenced, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( k + 1 ).
```

```
 X
   X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the n
   element vector x. On exit, X is overwritten with the tranformed vector x.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

   The vector and matrix arguments are not referenced when N = 0, or M = 0
```

Function/Subroutine Documentation
   subroutine stbsv (character UPLO, character TRANS, character DIAG, integer
       N, integer K, real, dimension(lda,*) A, integer LDA, real, dimension(*)
       X, integer INCX)
       STBSV

Purpose:
   STBSV  solves one of the systems of equations

      A*x = b,   or   A**T*x = b,

   where b and x are n element vectors and A is an n by n unit, or
   non-unit, upper or lower triangular band matrix, with ( k + 1 ) diagonals.

   No test for singularity or near-singularity is included in this
   routine. Such tests must be performed before calling this routine.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the equations to be solved as follows:

   TRANS = 'N' or 'n'   A*x = b.

   TRANS = 'T' or 't'   A**T*x = b.

   TRANS = 'C' or 'c'   A**T*x = b.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
```

```
  N must be at least zero.

K
  K is INTEGER
  On entry with UPLO = 'U' or 'u', K specifies the number of
  super-diagonals of the matrix A.
  On entry with UPLO = 'L' or 'l', K specifies the number of
  sub-diagonals of the matrix A.
  K must satisfy  0 .le. K.

A
  A is REAL array of DIMENSION ( LDA, n ).

  Before entry with UPLO = 'U' or 'u', the leading ( k + 1 )
  by n part of the array A must contain the upper triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row
  ( k + 1 ) of the array, the first super-diagonal starting at
  position 2 in row k, and so on. The top left k by k triangle
  of the array A is not referenced.

  The following program segment will transfer an upper
  triangular band matrix from conventional full matrix storage
  to band storage:

       DO 20, J = 1, N
          M = K + 1 - J
          DO 10, I = MAX( 1, J - K ), J
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Before entry with UPLO = 'L' or 'l', the leading ( k + 1 )
  by n part of the array A must contain the lower triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row 1 of
  the array, the first sub-diagonal starting at position 1 in
  row 2, and so on. The bottom right k by k triangle of the
  array A is not referenced.

  The following program segment will transfer a lower
  triangular band matrix from conventional full matrix storage
  to band storage:

       DO 20, J = 1, N
          M = 1 - J
          DO 10, I = J, MIN( N, J + K )
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE
```

```
  Note that when DIAG = 'U' or 'u' the elements of the array A
  corresponding to the diagonal elements of the matrix are not
  referenced, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( k + 1 ).

X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).

  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine stpmv (UPLO, TRANS, DIAG, N, AP, X, INCX)
          STPMV

Function/Subroutine Documentation
   subroutine stpmv (character UPLO, character TRANS, character DIAG, integer
       N, real, dimension(*) AP, real, dimension(*) X, integer INCX)
       STPMV

Purpose:
   STPMV  performs one of the matrix-vector operations

      x := A*x,   or   x := A**T*x,

   where x is an n element vector and  A is an n by n unit, or non-unit,
   upper or lower triangular matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   x := A*x.

   TRANS = 'T' or 't'   x := A**T*x.

   TRANS = 'C' or 'c'   x := A**T*x.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.
```

```
AP
  AP is REAL array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

  Before entry with  UPLO = 'U' or 'u', the array AP must
  contain the upper triangular matrix packed sequentially,
  column by column, so that AP( 1 ) contains a( 1, 1 ),
  AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
  respectively, and so on.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular matrix packed sequentially,
  column by column, so that AP( 1 ) contains a( 1, 1 ),
  AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 )
  respectively, and so on.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced, but are assumed to be unity.

X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x. On exit, X is overwritten with the
  tranformed vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine stpsv (UPLO, TRANS, DIAG, N, AP, X, INCX)
           STPSV

Function/Subroutine Documentation
   subroutine stpsv (character UPLO, character TRANS, character DIAG, integer
```

```
      N, real, dimension(*) AP, real, dimension(*) X, integer INCX)
      STPSV

Purpose:
   STPSV  solves one of the systems of equations

      A*x = b,   or   A**T*x = b,

   where b and x are n element vectors and A is an n by n unit, or
   non-unit, upper or lower triangular matrix, supplied in packed form.

   No test for singularity or near-singularity is included in this
   routine. Such tests must be performed before calling this routine.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the equations to be solved as follows:

   TRANS = 'N' or 'n'   A*x = b.

   TRANS = 'T' or 't'   A**T*x = b.

   TRANS = 'C' or 'c'   A**T*x = b.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 AP
```

```
  AP is REAL array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

  Before entry with  UPLO = 'U' or 'u', the array AP must
  contain the upper triangular matrix packed sequentially,
  column by column, so that AP( 1 ) contains a( 1, 1 ),
  AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
  respectively, and so on.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular matrix packed sequentially,
  column by column, so that AP( 1 ) contains a( 1, 1 ),
  AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 )
  respectively, and so on.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced, but are assumed to be unity.

X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).

  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine strmv (UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
           STRMV

Function/Subroutine Documentation
   subroutine strmv (character UPLO, character TRANS, character DIAG, integer
       N, real, dimension(lda,*) A, integer LDA, real, dimension(*) X, integer
       INCX)
       STRMV

Purpose:
   STRMV  performs one of the matrix-vector operations

      x := A*x,   or   x := A**T*x,
```

```
   where x is an n element vector and  A is an n by n unit, or non-unit,
   upper or lower triangular matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   x := A*x.

   TRANS = 'T' or 't'   x := A**T*x.

   TRANS = 'C' or 'c'   x := A**T*x.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 A
   A is REAL array of DIMENSION ( LDA, n ).

   Before entry with  UPLO = 'U' or 'u', the leading n by n
   upper triangular part of the array A must contain the upper
   triangular matrix and the strictly lower triangular part of
   A is not referenced.

   Before entry with UPLO = 'L' or 'l', the leading n by n
   lower triangular part of the array A must contain the lower
   triangular matrix and the strictly upper triangular part of
   A is not referenced.
```

```
  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced either, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).

X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x. On exit, X is overwritten with the
  tranformed vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine strsv (UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
           STRSV

Function/Subroutine Documentation
   subroutine strsv (character UPLO, character TRANS, character DIAG, integer
       N, real, dimension(lda,*) A, integer LDA, real, dimension(*) X, integer
       INCX)
       STRSV

Purpose:
   STRSV  solves one of the systems of equations

     A*x = b,   or   A**T*x = b,

   where b and x are n element vectors and A is an n by n unit, or
   non-unit, upper or lower triangular matrix.

   No test for singularity or near-singularity is included in this
   routine. Such tests must be performed before calling this routine.

Parameters:

 UPLO
   UPLO is CHARACTER*1
```

```
  On entry, UPLO specifies whether the matrix is an upper or
  lower triangular matrix as follows:

  UPLO = 'U' or 'u'   A is an upper triangular matrix.

  UPLO = 'L' or 'l'   A is a lower triangular matrix.

TRANS
  TRANS is CHARACTER*1
  On entry, TRANS specifies the equations to be solved as follows:

  TRANS = 'N' or 'n'   A*x = b.

  TRANS = 'T' or 't'   A**T*x = b.

  TRANS = 'C' or 'c'   A**T*x = b.

DIAG
  DIAG is CHARACTER*1
  On entry, DIAG specifies whether or not A is unit
  triangular as follows:

  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

A
  A is REAL array of DIMENSION ( LDA, n ).

  Before entry with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular matrix and the strictly lower triangular part of
  A is not referenced.

  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular matrix and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced either, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
```

```
  in the calling (sub) program. LDA must be at least max( 1, n ).

 X
  X is REAL array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

 INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

 NAME
      DGBMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y,

 SYNOPSIS
      SUBROUTINE DGBMV ( TRANS, M, N, KL, KU, ALPHA, A, LDA, X,
                         INCX, BETA, Y, INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, KL, KU, LDA, M, N

          CHARACTER*1  TRANS

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DGBMV  performs one of the matrix-vector operations

      where alpha and beta are scalars, x and y are vectors and A
      is an m by n band matrix, with kl sub-diagonals and ku
      super-diagonals.

 PARAMETERS
      TRANS  - CHARACTER*1.
             On entry, TRANS specifies the operation to be per-
             formed as follows:

             TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

             TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

             TRANS = 'C' or 'c'   y := alpha*A'*x + beta*y.

             Unchanged on exit.

      M      - INTEGER.
             On entry, M specifies the number of rows of the
             matrix A.  M must be at least zero.  Unchanged on
             exit.

      N      - INTEGER.
             On entry, N specifies the number of columns of the
             matrix A.  N must be at least zero.  Unchanged on
             exit.
```

```
KL     - INTEGER.
         On entry, KL specifies the number of sub-diagonals of
         the matrix A. KL must satisfy  0 .le. KL.  Unchanged
         on exit.

KU     - INTEGER.
         On entry, KU specifies the number of super-diagonals
         of the matrix A. KU must satisfy  0 .le. KU.
         Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
         On entry, ALPHA specifies the scalar alpha.
         Unchanged on exit.

A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
         Before entry, the leading ( kl + ku + 1 ) by n part
         of the array A must contain the matrix of coeffi-
         cients, supplied column by column, with the leading
         diagonal of the matrix in row ( ku + 1 ) of the
         array, the first super-diagonal starting at position
         2 in row ku, the first sub-diagonal starting at posi-
         tion 1 in row ( ku + 2 ), and so on.  Elements in the
         array A that do not correspond to elements in the
         band matrix (such as the top left ku by ku triangle)
         are not referenced.  The following program segment
         will transfer a band matrix from conventional full
         matrix storage to band storage:

         DO 20, J = 1, N K = KU + 1 - J DO 10, I = MAX( 1, J -
         KU ), MIN( M, J + KL ) A( K + I, J ) = matrix( I, J )
         10    CONTINUE 20 CONTINUE

         Unchanged on exit.

LDA    - INTEGER.
         On entry, LDA specifies the first dimension of A as
         declared in the calling (sub) program. LDA must be at
         least ( kl + ku + 1 ).  Unchanged on exit.

X      - DOUBLE PRECISION array of DIMENSION at least
         ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
         and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
         Before entry, the incremented array X must contain
         the vector x.  Unchanged on exit.

INCX   - INTEGER.
         On entry, INCX specifies the increment for the ele-
         ments of X. INCX must not be zero.  Unchanged on
         exit.
```

```
      BETA   - DOUBLE PRECISION.
             On entry, BETA specifies the scalar beta. When BETA
             is supplied as zero then Y need not be set on input.
             Unchanged on exit.

      Y      - DOUBLE PRECISION array of DIMENSION at least
             ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'

             and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
             Before entry, the incremented array Y must contain
             the vector y. On exit, Y is overwritten by the
             updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.

 NAME
      DGEMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y,

 SYNOPSIS
      SUBROUTINE DGEMV ( TRANS, M, N, ALPHA, A, LDA, X, INCX,
                         BETA, Y, INCY )

          DOUBLE       PRECISION ALPHA, BETA
```

```
     INTEGER      INCX, INCY, LDA, M, N

     CHARACTER*1  TRANS

     DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

PURPOSE
     DGEMV  performs one of the matrix-vector operations

     where alpha and beta are scalars, x and y are vectors and A
     is an m by n matrix.

PARAMETERS
     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

            TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

            TRANS = 'C' or 'c'   y := alpha*A'*x + beta*y.

            Unchanged on exit.

     M      - INTEGER.
            On entry, M specifies the number of rows of the
            matrix A.  M must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix A.  N must be at least zero.  Unchanged on
            exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
            Before entry, the leading m by n part of the array A

            must contain the matrix of coefficients.  Unchanged
            on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, m ).  Unchanged on exit.
```

```
X      - DOUBLE PRECISION array of DIMENSION at least
         ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
         and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
         Before entry, the incremented array X must contain
         the vector x.  Unchanged on exit.

INCX   - INTEGER.
         On entry, INCX specifies the increment for the ele-
         ments of X. INCX must not be zero.  Unchanged on
         exit.

BETA   - DOUBLE PRECISION.
         On entry, BETA specifies the scalar beta. When BETA
         is supplied as zero then Y need not be set on input.
         Unchanged on exit.

Y      - DOUBLE PRECISION array of DIMENSION at least
         ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
         and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
         Before entry with BETA non-zero, the incremented
         array Y must contain the vector y. On exit, Y is
         overwritten by the updated vector y.

INCY   - INTEGER.
         On entry, INCY specifies the increment for the ele-
         ments of Y. INCY must not be zero.  Unchanged on
         exit.

 NAME
      DGER - perform the rank 1 operation   A := alpha*x*y' + A,

 SYNOPSIS
      SUBROUTINE DGER ( M, N, ALPHA, X, INCX, Y, INCY, A, LDA )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, INCY, LDA, M, N

          DOUBLE      PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DGER   performs the rank 1 operation

      where alpha is a scalar, x is an m element vector, y is an n
```

```
     element vector and A is an m by n matrix.

PARAMETERS
     M      - INTEGER.
            On entry, M specifies the number of rows of the
            matrix A.  M must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix A.  N must be at least zero.  Unchanged on
            exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - DOUBLE PRECISION array of dimension at least
            ( 1 + ( m - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the m element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

     Y      - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
            incremented array Y must contain the n element vector
            y.  Unchanged on exit.

     INCY   - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on

            exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
            Before entry, the leading m by n part of the array A
            must contain the matrix of coefficients. On exit, A
            is overwritten by the updated matrix.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, m ).  Unchanged on exit.

            -------

 NAME
      DSBMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE DSBMV ( UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA,
                         Y, INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, K, LDA, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

 PURPOSE
      DSBMV  performs the matrix-vector  operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n symmetric band matrix, with k
      super-diagonals.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the upper or lower
             triangular part of the band matrix A is being sup-
             plied as follows:

             UPLO = 'U' or 'u'   The upper triangular part of A is
             being supplied.

             UPLO = 'L' or 'l'   The lower triangular part of A is
             being supplied.

             Unchanged on exit.

      N      - INTEGER.
             On entry, N specifies the order of the matrix A.  N
             must be at least zero.  Unchanged on exit.

      K      - INTEGER.
```

```
        On entry, K specifies the number of super-diagonals
        of the matrix A. K must satisfy  0 .le. K.  Unchanged
        on exit.

ALPHA   - DOUBLE PRECISION.
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

A       - DOUBLE PRECISION array of DIMENSION ( LDA, n ).

        Before entry with UPLO = 'U' or 'u', the leading ( k
        + 1 ) by n part of the array A must contain the upper
        triangular band part of the symmetric matrix, sup-
        plied column by column, with the leading diagonal of
        the matrix in row ( k + 1 ) of the array, the first
        super-diagonal starting at position 2 in row k, and
        so on. The top left k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer the upper triangular part of a symmetric
        band matrix from conventional full matrix storage to
        band storage:

        DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
        K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
        20 CONTINUE

        Before entry with UPLO = 'L' or 'l', the leading ( k
        + 1 ) by n part of the array A must contain the lower
        triangular band part of the symmetric matrix, sup-
        plied column by column, with the leading diagonal of
        the matrix in row 1 of the array, the first sub-
        diagonal starting at position 1 in row 2, and so on.
        The bottom right k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer the lower triangular part of a symmetric
        band matrix from conventional full matrix storage to
        band storage:

        DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
        ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
        CONTINUE

        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least ( k + 1 ).  Unchanged on exit.

X       - DOUBLE PRECISION array of DIMENSION at least
```

```
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the vector x.
             Unchanged on exit.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.

      BETA   - DOUBLE PRECISION.
             On entry, BETA specifies the scalar beta.  Unchanged
             on exit.

      Y      - DOUBLE PRECISION array of DIMENSION at least
             ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
             incremented array Y must contain the vector y. On
             exit, Y is overwritten by the updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.

 NAME
      DSPMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE DSPMV ( UPLO, N, ALPHA, AP, X, INCX, BETA, Y,
                         INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION AP( * ), X( * ), Y( * )
```

```
PURPOSE
     DSPMV  performs the matrix-vector operation

     where alpha and beta are scalars, x and y are n element vec-
     tors and A is an n by n symmetric matrix, supplied in packed
     form.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the upper or lower
              triangular part of the matrix A is supplied in the
              packed array AP as follows:

              UPLO = 'U' or 'u'   The upper triangular part of A is
              supplied in AP.

              UPLO = 'L' or 'l'   The lower triangular part of A is
              supplied in AP.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     AP     - DOUBLE PRECISION array of DIMENSION at least
              ( ( n*( n + 1 ) )/2 ).  Before entry with UPLO = 'U'
              or 'u', the array AP must contain the upper triangu-
              lar part of the symmetric matrix packed sequentially,
              column by column, so that AP( 1 ) contains a( 1, 1 ),
              AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )

              respectively, and so on.  Before entry with UPLO =
              'L' or 'l', the array AP must contain the lower tri-
              angular part of the symmetric matrix packed sequen-
              tially, column by column, so that AP( 1 ) contains a(
              1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a(
              3, 1 ) respectively, and so on.  Unchanged on exit.

     X      - DOUBLE PRECISION array of dimension at least
              ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
              incremented array X must contain the n element vector
              x.  Unchanged on exit.

     INCX   - INTEGER.
              On entry, INCX specifies the increment for the ele-
```

```
             ments of X. INCX must not be zero.  Unchanged on
             exit.

      BETA   - DOUBLE PRECISION.
             On entry, BETA specifies the scalar beta. When BETA
             is supplied as zero then Y need not be set on input.
             Unchanged on exit.

      Y      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
             incremented array Y must contain the n element vector
             y. On exit, Y is overwritten by the updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.
```

 NAME
      DSPR - perform the symmetric rank 1 operation   A :=
      alpha*x*x' + A,

 SYNOPSIS
      SUBROUTINE DSPR ( UPLO, N, ALPHA, X, INCX, AP )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, N

          CHARACTER*1 UPLO

          DOUBLE      PRECISION AP( * ), X( * )

 PURPOSE
      DSPR    performs the symmetric rank 1 operation

      where alpha is a real scalar, x is an n element vector and A
      is an n by n symmetric matrix, supplied in packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the upper or lower
             triangular part of the matrix A is supplied in the
             packed array AP as follows:

             UPLO = 'U' or 'u'   The upper triangular part of A is
             supplied in AP.

             UPLO = 'L' or 'l'   The lower triangular part of A is
             supplied in AP.

             Unchanged on exit.
```

```
N      - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
         On entry, ALPHA specifies the scalar alpha.
         Unchanged on exit.

X      - DOUBLE PRECISION array of dimension at least
         ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
         incremented array X must contain the n element vector
         x.  Unchanged on exit.

INCX   - INTEGER.
         On entry, INCX specifies the increment for the ele-
         ments of X. INCX must not be zero.  Unchanged on

         exit.

AP     - DOUBLE PRECISION array of DIMENSION at least
         ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
         or 'u', the array AP must contain the upper triangu-
         lar part of the symmetric matrix packed sequentially,
         column by column, so that AP( 1 ) contains a( 1, 1 ),
         AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
         respectively, and so on. On exit, the array AP is
         overwritten by the upper triangular part of the
         updated matrix.  Before entry with UPLO = 'L' or 'l',
         the array AP must contain the lower triangular part
         of the symmetric matrix packed sequentially, column
         by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
         ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
         tively, and so on. On exit, the array AP is overwrit-
         ten by the lower triangular part of the updated
         matrix.

 NAME
      DSPR2 - perform the symmetric rank 2 operation   A :=
      alpha*x*y' + alpha*y*x' + A,

 SYNOPSIS
      SUBROUTINE DSPR2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, AP )

          DOUBLE       PRECISION ALPHA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION AP( * ), X( * ), Y( * )

 PURPOSE
      DSPR2  performs the symmetric rank 2 operation

      where alpha is a scalar, x and y are n element vectors and A
      is an n by n symmetric matrix, supplied in packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the upper or lower
               triangular part of the matrix A is supplied in the
```

```
        packed array AP as follows:

        UPLO = 'U' or 'u'   The upper triangular part of A is
        supplied in AP.

        UPLO = 'L' or 'l'   The lower triangular part of A is
        supplied in AP.

        Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the order of the matrix A.  N
        must be at least zero.  Unchanged on exit.

ALPHA   - DOUBLE PRECISION.
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

X       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element vector
        x.  Unchanged on exit.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on

        exit.

Y       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
        incremented array Y must contain the n element vector
        y.  Unchanged on exit.

INCY    - INTEGER.
        On entry, INCY specifies the increment for the ele-
        ments of Y. INCY must not be zero.  Unchanged on
        exit.

AP      - DOUBLE PRECISION array of DIMENSION at least
        ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
        or 'u', the array AP must contain the upper triangu-
        lar part of the symmetric matrix packed sequentially,
        column by column, so that AP( 1 ) contains a( 1, 1 ),
        AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
        respectively, and so on. On exit, the array AP is
        overwritten by the upper triangular part of the
        updated matrix.  Before entry with UPLO = 'L' or 'l',
        the array AP must contain the lower triangular part
        of the symmetric matrix packed sequentially, column
```

```
by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
tively, and so on. On exit, the array AP is overwrit-
ten by the lower triangular part of the updated
matrix.
```

 NAME
      DSYMV - perform the matrix-vector operation   y := alpha*A*x
      + beta*y,

 SYNOPSIS
      SUBROUTINE DSYMV ( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y,
                         INCY )

          DOUBLE       PRECISION ALPHA, BETA

          INTEGER      INCX, INCY, LDA, N
```

```
      CHARACTER*1  UPLO

      DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )

PURPOSE
     DSYMV  performs the matrix-vector  operation

     where alpha and beta are scalars, x and y are n element vec-
     tors and A is an n by n symmetric matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the upper or lower
              triangular part of the array A is to be referenced as
              follows:

              UPLO = 'U' or 'u'   Only the upper triangular part of
              A is to be referenced.

              UPLO = 'L' or 'l'   Only the lower triangular part of
              A is to be referenced.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
              Before entry with  UPLO = 'U' or 'u', the leading n
              by n upper triangular part of the array A must con-
              tain the upper triangular part of the symmetric
              matrix and the strictly lower triangular part of A is
              not referenced.  Before entry with UPLO = 'L' or 'l',
              the leading n by n lower triangular part of the array

              A must contain the lower triangular part of the sym-
              metric matrix and the strictly upper triangular part
              of A is not referenced.  Unchanged on exit.

     LDA    - INTEGER.
              On entry, LDA specifies the first dimension of A as
              declared in the calling (sub) program. LDA must be at
              least max( 1, n ).  Unchanged on exit.

     X      - DOUBLE PRECISION array of dimension at least
```

```
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the n element vector
             x.  Unchanged on exit.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.

      BETA   - DOUBLE PRECISION.
             On entry, BETA specifies the scalar beta. When BETA
             is supplied as zero then Y need not be set on input.
             Unchanged on exit.

      Y      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
             incremented array Y must contain the n element vector
             y. On exit, Y is overwritten by the updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.

 NAME
      DSYR - perform the symmetric rank 1 operation   A :=
      alpha*x*x' + A,

 SYNOPSIS
```

```
     SUBROUTINE DSYR ( UPLO, N, ALPHA, X, INCX, A, LDA )

         DOUBLE      PRECISION ALPHA

         INTEGER     INCX, LDA, N

         CHARACTER*1 UPLO

         DOUBLE      PRECISION A( LDA, * ), X( * )

PURPOSE
     DSYR   performs the symmetric rank 1 operation

     where alpha is a real scalar, x is an n element vector and A
     is an n by n symmetric matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the array A is to be referenced as
            follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            A is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            A is to be referenced.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on

            exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
```

```
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular part of the symmetric
            matrix and the strictly lower triangular part of A is
            not referenced. On exit, the upper triangular part of
            the array A is overwritten by the upper triangular
            part of the updated matrix.  Before entry with UPLO =
            'L' or 'l', the leading n by n lower triangular part
            of the array A must contain the lower triangular part
            of the symmetric matrix and the strictly upper tri-
            angular part of A is not referenced. On exit, the
            lower triangular part of the array A is overwritten
            by the lower triangular part of the updated matrix.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least max( 1, n ).  Unchanged on exit.
```

 NAME
      DSYR2 - perform the symmetric rank 2 operation   A :=
      alpha*x*y' + alpha*y*x' + A,

 SYNOPSIS
      SUBROUTINE DSYR2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA
                       )

          DOUBLE       PRECISION ALPHA

          INTEGER      INCX, INCY, LDA, N

          CHARACTER*1  UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * ), Y( * )
```

```
PURPOSE
     DSYR2  performs the symmetric rank 2 operation

     where alpha is a scalar, x and y are n element vectors and A
     is an n by n symmetric matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the array A is to be referenced as
            follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            A is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            A is to be referenced.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the

            elements of X. INCX must not be zero.  Unchanged on
            exit.

     Y      - DOUBLE PRECISION array of dimension at least
            ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
            incremented array Y must contain the n element vector
            y.  Unchanged on exit.

     INCY   - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
            exit.

     A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
```

```
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular part of the symmetric
            matrix and the strictly lower triangular part of A is
            not referenced. On exit, the upper triangular part of
            the array A is overwritten by the upper triangular
            part of the updated matrix.  Before entry with UPLO =
            'L' or 'l', the leading n by n lower triangular part
            of the array A must contain the lower triangular part
            of the symmetric matrix and the strictly upper tri-
            angular part of A is not referenced. On exit, the
            lower triangular part of the array A is overwritten
            by the lower triangular part of the updated matrix.

      LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, n ).  Unchanged on exit.

 NAME
      DTBMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x,

 SYNOPSIS
      SUBROUTINE DTBMV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                       )

          INTEGER      INCX, K, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * )
```

```
PURPOSE
     DTBMV  performs one of the matrix-vector operations

     where x is an n element vector and  A is an n by n unit, or
     non-unit, upper or lower triangular band matrix, with ( k +
     1 ) diagonals.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   x := A*x.

            TRANS = 'T' or 't'   x := A'*x.

            TRANS = 'C' or 'c'   x := A'*x.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     K      - INTEGER.
            On entry with UPLO = 'U' or 'u', K specifies the
            number of super-diagonals of the matrix A.  On entry
            with UPLO = 'L' or 'l', K specifies the number of
```

```
        sub-diagonals of the matrix A.  K must satisfy  0
        .le. K.  Unchanged on exit.

A       - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
        Before entry with UPLO = 'U' or 'u', the leading ( k
        + 1 ) by n part of the array A must contain the upper
        triangular band part of the matrix of coefficients,
        supplied column by column, with the leading diagonal
        of the matrix in row ( k + 1 ) of the array, the
        first super-diagonal starting at position 2 in row k,
        and so on. The top left k by k triangle of the array
        A is not referenced.  The following program segment
        will transfer an upper triangular band matrix from
        conventional full matrix storage to band storage:

        DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
        K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
        20 CONTINUE

        Before entry with UPLO = 'L' or 'l', the leading ( k
        + 1 ) by n part of the array A must contain the lower
        triangular band part of the matrix of coefficients,
        supplied column by column, with the leading diagonal
        of the matrix in row 1 of the array, the first sub-
        diagonal starting at position 1 in row 2, and so on.
        The bottom right k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer a lower triangular band matrix from conven-
        tional full matrix storage to band storage:

        DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
        ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
        CONTINUE

        Note that when DIAG = 'U' or 'u' the elements of the
        array A corresponding to the diagonal elements of the
        matrix are not referenced, but are assumed to be
        unity.  Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least ( k + 1 ).  Unchanged on exit.

X       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element vector
        x. On exit, X is overwritten with the transformed
        vector x.
```

```
      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.
```

 NAME
      DTBSV - solve one of the systems of equations   A*x = b, or
      A'*x = b,

 SYNOPSIS
      SUBROUTINE DTBSV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                       )

          INTEGER      INCX, K, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * )

 PURPOSE
      DTBSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular band matrix, with ( k
      + 1 ) diagonals.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
      this routine.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:
```

```
         UPLO = 'U' or 'u'   A is an upper triangular matrix.

         UPLO = 'L' or 'l'   A is a lower triangular matrix.

         Unchanged on exit.

TRANS  - CHARACTER*1.
         On entry, TRANS specifies the equations to be solved
         as follows:

         TRANS = 'N' or 'n'   A*x = b.

         TRANS = 'T' or 't'   A'*x = b.

         TRANS = 'C' or 'c'   A'*x = b.

         Unchanged on exit.

DIAG   - CHARACTER*1.
         On entry, DIAG specifies whether or not A is unit
         triangular as follows:

         DIAG = 'U' or 'u'   A is assumed to be unit triangu-
         lar.

         DIAG = 'N' or 'n'   A is not assumed to be unit tri-
         angular.

         Unchanged on exit.

N      - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

K      - INTEGER.
         On entry with UPLO = 'U' or 'u', K specifies the
         number of super-diagonals of the matrix A.  On entry
         with UPLO = 'L' or 'l', K specifies the number of
         sub-diagonals of the matrix A.  K must satisfy  0
         .le. K.  Unchanged on exit.

A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
         Before entry with UPLO = 'U' or 'u', the leading ( k
         + 1 ) by n part of the array A must contain the upper
         triangular band part of the matrix of coefficients,
         supplied column by column, with the leading diagonal
         of the matrix in row ( k + 1 ) of the array, the
         first super-diagonal starting at position 2 in row k,
         and so on. The top left k by k triangle of the array
```

```
A is not referenced.  The following program segment
will transfer an upper triangular band matrix from
conventional full matrix storage to band storage:

DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading ( k
+ 1 ) by n part of the array A must contain the lower
triangular band part of the matrix of coefficients,
supplied column by column, with the leading diagonal
of the matrix in row 1 of the array, the first sub-
diagonal starting at position 1 in row 2, and so on.
The bottom right k by k triangle of the array A is
not referenced.  The following program segment will
transfer a lower triangular band matrix from conven-
tional full matrix storage to band storage:

DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the
array A corresponding to the diagonal elements of the

matrix are not referenced, but are assumed to be
unity.  Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least ( k + 1 ).  Unchanged on exit.

X       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element
        right-hand side vector b. On exit, X is overwritten
        with the solution vector x.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
        exit.
```

 NAME
      DTPMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x,

 SYNOPSIS
      SUBROUTINE DTPMV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION AP( * ), X( * )

 PURPOSE
      DTPMV  performs one of the matrix-vector operations

      where x is an n element vector and  A is an n by n unit, or
      non-unit, upper or lower triangular matrix, supplied in
      packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the matrix is an
             upper or lower triangular matrix as follows:

             UPLO = 'U' or 'u'   A is an upper triangular matrix.

             UPLO = 'L' or 'l'   A is a lower triangular matrix.

             Unchanged on exit.

      TRANS  - CHARACTER*1.
             On entry, TRANS specifies the operation to be per-
             formed as follows:

             TRANS = 'N' or 'n'   x := A*x.
```

```
        TRANS = 'T' or 't'   x := A'*x.

        TRANS = 'C' or 'c'   x := A'*x.

        Unchanged on exit.

DIAG    - CHARACTER*1.
        On entry, DIAG specifies whether or not A is unit
        triangular as follows:

        DIAG = 'U' or 'u'   A is assumed to be unit triangu-
        lar.

        DIAG = 'N' or 'n'   A is not assumed to be unit

        triangular.

        Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the order of the matrix A.  N
        must be at least zero.  Unchanged on exit.

AP      - DOUBLE PRECISION array of DIMENSION at least
        ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
        or 'u', the array AP must contain the upper triangu-
        lar matrix packed sequentially, column by column, so
        that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
        contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
        on.  Before entry with UPLO = 'L' or 'l', the array
        AP must contain the lower triangular matrix packed
        sequentially, column by column, so that AP( 1 ) con-
        tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
        ) and a( 3, 1 ) respectively, and so on.  Note that
        when  DIAG = 'U' or 'u', the diagonal elements of A
        are not referenced, but are assumed to be unity.
        Unchanged on exit.

X       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element vector
        x. On exit, X is overwritten with the transformed
        vector x.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
        exit.

 NAME
      DTPSV - solve one of the systems of equations   A*x = b, or
      A'*x = b,

 SYNOPSIS
      SUBROUTINE DTPSV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION AP( * ), X( * )

 PURPOSE
      DTPSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular matrix, supplied in
      packed form.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
      this routine.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the matrix is an
             upper or lower triangular matrix as follows:

             UPLO = 'U' or 'u'   A is an upper triangular matrix.

             UPLO = 'L' or 'l'   A is a lower triangular matrix.

             Unchanged on exit.

      TRANS  - CHARACTER*1.
             On entry, TRANS specifies the equations to be solved
```

```
        as follows:

        TRANS = 'N' or 'n'   A*x = b.

        TRANS = 'T' or 't'   A'*x = b.

        TRANS = 'C' or 'c'   A'*x = b.

        Unchanged on exit.

DIAG    - CHARACTER*1.
        On entry, DIAG specifies whether or not A is unit
        triangular as follows:

        DIAG = 'U' or 'u'   A is assumed to be unit triangu-
        lar.

        DIAG = 'N' or 'n'   A is not assumed to be unit tri-
        angular.

        Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the order of the matrix A.  N
        must be at least zero.  Unchanged on exit.

AP      - DOUBLE PRECISION array of DIMENSION at least
        ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
        or 'u', the array AP must contain the upper triangu-
        lar matrix packed sequentially, column by column, so
        that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
        contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
        on.  Before entry with UPLO = 'L' or 'l', the array
        AP must contain the lower triangular matrix packed
        sequentially, column by column, so that AP( 1 ) con-
        tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
        ) and a( 3, 1 ) respectively, and so on.  Note that
        when  DIAG = 'U' or 'u', the diagonal elements of A
        are not referenced, but are assumed to be unity.
        Unchanged on exit.

X       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element
        right-hand side vector b. On exit, X is overwritten
        with the solution vector x.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
```

exit.

 NAME
      DTRMV - perform one of the matrix-vector operations   x :=
      A*x, or x := A'*x,

 SYNOPSIS
      SUBROUTINE DTRMV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

          INTEGER      INCX, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          DOUBLE       PRECISION A( LDA, * ), X( * )

 PURPOSE
      DTRMV  performs one of the matrix-vector operations

      where x is an n element vector and  A is an n by n unit, or
      non-unit, upper or lower triangular matrix.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the matrix is an
             upper or lower triangular matrix as follows:

             UPLO = 'U' or 'u'   A is an upper triangular matrix.

             UPLO = 'L' or 'l'   A is a lower triangular matrix.

             Unchanged on exit.

      TRANS  - CHARACTER*1.
             On entry, TRANS specifies the operation to be per-
             formed as follows:
```

```
        TRANS = 'N' or 'n'   x := A*x.

        TRANS = 'T' or 't'   x := A'*x.

        TRANS = 'C' or 'c'   x := A'*x.

        Unchanged on exit.

DIAG    - CHARACTER*1.
        On entry, DIAG specifies whether or not A is unit
        triangular as follows:

        DIAG = 'U' or 'u'   A is assumed to be unit triangu-
        lar.

        DIAG = 'N' or 'n'   A is not assumed to be unit tri-
        angular.

        Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the order of the matrix A.  N
        must be at least zero.  Unchanged on exit.

A       - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
        Before entry with  UPLO = 'U' or 'u', the leading n
        by n upper triangular part of the array A must con-
        tain the upper triangular matrix and the strictly
        lower triangular part of A is not referenced.  Before
        entry with UPLO = 'L' or 'l', the leading n by n
        lower triangular part of the array A must contain the
        lower triangular matrix and the strictly upper tri-
        angular part of A is not referenced.  Note that when
        DIAG = 'U' or 'u', the diagonal elements of A are not
        referenced either, but are assumed to be unity.
        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least max( 1, n ).  Unchanged on exit.

X       - DOUBLE PRECISION array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element vector
        x. On exit, X is overwritten with the transformed
        vector x.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
```

```
ments of X. INCX must not be zero.  Unchanged on
exit.
```

 NAME
      DTRSV - solve one of the systems of equations   A*x = b, or
      A'*x = b,

 SYNOPSIS
      SUBROUTINE DTRSV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

          INTEGER      INCX, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO
```

```
      DOUBLE       PRECISION A( LDA, * ), X( * )

PURPOSE
     DTRSV  solves one of the systems of equations

     where b and x are n element vectors and A is an n by n unit,
     or non-unit, upper or lower triangular matrix.

     No test for singularity or near-singularity is included in
     this routine. Such tests must be performed before calling
     this routine.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the matrix is an
              upper or lower triangular matrix as follows:

              UPLO = 'U' or 'u'   A is an upper triangular matrix.

              UPLO = 'L' or 'l'   A is a lower triangular matrix.

              Unchanged on exit.

     TRANS  - CHARACTER*1.
              On entry, TRANS specifies the equations to be solved
              as follows:

              TRANS = 'N' or 'n'   A*x = b.

              TRANS = 'T' or 't'   A'*x = b.

              TRANS = 'C' or 'c'   A'*x = b.

              Unchanged on exit.

     DIAG   - CHARACTER*1.
              On entry, DIAG specifies whether or not A is unit
              triangular as follows:

              DIAG = 'U' or 'u'   A is assumed to be unit

              triangular.

              DIAG = 'N' or 'n'   A is not assumed to be unit tri-
              angular.

              Unchanged on exit.

     N      - INTEGER.
```

```
             On entry, N specifies the order of the matrix A.  N
             must be at least zero.  Unchanged on exit.

      A      - DOUBLE PRECISION array of DIMENSION ( LDA, n ).
             Before entry with  UPLO = 'U' or 'u', the leading n
             by n upper triangular part of the array A must con-
             tain the upper triangular matrix and the strictly
             lower triangular part of A is not referenced.  Before
             entry with UPLO = 'L' or 'l', the leading n by n
             lower triangular part of the array A must contain the
             lower triangular matrix and the strictly upper tri-
             angular part of A is not referenced.  Note that when
             DIAG = 'U' or 'u', the diagonal elements of A are not
             referenced either, but are assumed to be unity.
             Unchanged on exit.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least max( 1, n ).  Unchanged on exit.

      X      - DOUBLE PRECISION array of dimension at least
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the n element
             right-hand side vector b. On exit, X is overwritten
             with the solution vector x.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbmv (TRANS, M, N, KL, KU, ALPHA, A, LDA, X, INCX, BETA, Y,
           INCY)
           CGBMV

Function/Subroutine Documentation
   subroutine cgbmv (character TRANS, integer M, integer N, integer KL,
       integer KU, complex ALPHA, complex, dimension(lda,*) A, integer LDA,
       complex, dimension(*) X, integer INCX, complex BETA, complex,
       dimension(*) Y, integer INCY)
       CGBMV

Purpose:
   CGBMV  performs one of the matrix-vector operations

     y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,   or

   y := alpha*A**H*x + beta*y,

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n band matrix, with kl sub-diagonals and ku super-diagonals.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

   TRANS = 'T' or 't'   y := alpha*A**T*x + beta*y.

   TRANS = 'C' or 'c'   y := alpha*A**H*x + beta*y.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.
```

```
KL
  KL is INTEGER
  On entry, KL specifies the number of sub-diagonals of the
  matrix A. KL must satisfy  0 .le. KL.

KU
  KU is INTEGER
  On entry, KU specifies the number of super-diagonals of the
  matrix A. KU must satisfy  0 .le. KU.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).

  Before entry, the leading ( kl + ku + 1 ) by n part of th
  e
  array A must contain the matrix of coefficients, supplied
  column by column, with the leading diagonal of the matrix in
  row ( ku + 1 ) of the array, the first super-diagonal
  starting at position 2 in row ku, the first sub-diagonal
  starting at position 1 in row ( ku + 2 ), and so on.
  Elements in the array A that do not correspond to elements
  in the band matrix (such as the top left ku by ku triangle)
  are not referenced.

  The following program segment will transfer a band matrix
  from conventional full matrix storage to band storage:

       DO 20, J = 1, N
          K = KU + 1 - J
          DO 10, I = MAX( 1, J - KU ), MIN( M, J + KL )
             A( K + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( kl + ku + 1 ).

X
  X is COMPLEX array of DIMENSION at least
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.
```

```
 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

 BETA
   BETA is COMPLEX
   On entry, BETA specifies the scalar beta. When BETA is
   supplied as zero then Y need not be set on input.

 Y
   Y is COMPLEX array of DIMENSION at least
   ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
   and at least
   ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
   Before entry, the incremented array Y must contain the
   vector y. On exit, Y is overwritten by the updated vector y.

 INCY
   INCY is INTEGER
   On entry, INCY specifies the increment for the elements of Y.
   INCY must not be zero.

   The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgemv (TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           CGEMV

Function/Subroutine Documentation
   subroutine cgemv (character TRANS, integer M, integer N, complex ALPHA,
       complex, dimension(lda,*) A, integer LDA, complex, dimension(*) X,
       integer INCX, complex BETA, complex, dimension(*) Y, integer INCY)
       CGEMV

Purpose:
   CGEMV performs one of the matrix-vector operations

   y := alpha*A*x + beta*y,   or   y := alpha*A**T*x + beta*y,   or

   y := alpha*A**H*x + beta*y,

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

   TRANS = 'T' or 't'   y := alpha*A**T*x + beta*y.

   TRANS = 'C' or 'c'   y := alpha*A**H*x + beta*y.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
```

```
N

  N is INTEGER
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, m ).

X
  X is COMPLEX array of DIMENSION at least
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

Y
  Y is COMPLEX array of DIMENSION at least
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
```

```
INCY must not be zero.

The vector and matrix arguments are not referenced when N = 0, or M = 0
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgerc (M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
           CGERC

Function/Subroutine Documentation
   subroutine cgerc (integer M, integer N, complex ALPHA, complex,
       dimension(*) X, integer INCX, complex, dimension(*) Y, integer INCY,
       complex, dimension(lda,*) A, integer LDA)
       CGERC

Purpose:
   CGERC  performs the rank 1 operation

   A := alpha*x*y**H + A,

   where alpha is a scalar, x is an m element vector, y is an n element
   vector and A is an m by n matrix.

Parameters:

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is COMPLEX
   On entry, ALPHA specifies the scalar alpha.

 X
   X is COMPLEX array of dimension at least ( 1 + ( m - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the m
   element vector x.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

 Y
   Y is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
   Before entry, the incremented array Y must contain the n
```

```
  element vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients. On exit, A is
  overwritten by the updated matrix.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, m ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgeru (M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
           CGERU

Function/Subroutine Documentation
   subroutine cgeru (integer M, integer N, complex ALPHA, complex,
       dimension(*) X, integer INCX, complex, dimension(*) Y, integer INCY,
       complex, dimension(lda,*) A, integer LDA)
       CGERU

Purpose:
   CGERU  performs the rank 1 operation

      A := alpha*x*y**T + A,

   where alpha is a scalar, x is an m element vector, y is an n element
   vector and A is an m by n matrix.

Parameters:

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.

 ALPHA
```

```
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

X
  X is COMPLEX array of dimension at least ( 1 + ( m - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the m
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

Y
  Y is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients. On exit, A is
  overwritten by the updated matrix.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, m ).
```

Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine chbmv (UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           CHBMV

Function/Subroutine Documentation
   subroutine chbmv (character UPLO, integer N, integer K, complex ALPHA,
       complex, dimension(lda,*) A, integer LDA, complex, dimension(*) X,
       integer INCX, complex BETA, complex, dimension(*) Y, integer INCY)
       CHBMV

Purpose:
   CHBMV  performs the matrix-vector  operation

      y := alpha*A*x + beta*y,
```

```
  where alpha and beta are scalars, x and y are n element vectors and
  A is an n by n hermitian band matrix, with k super-diagonals.

Parameters:

 UPLO
  UPLO is CHARACTER*1
  On entry, UPLO specifies whether the upper or lower
  triangular part of the band matrix A is being supplied as follows:

  UPLO = 'U' or 'u'   The upper triangular part of A is being supplied.

  UPLO = 'L' or 'l'   The lower triangular part of A is being supplied.

 N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

 K
  K is INTEGER
  On entry, K specifies the number of super-diagonals of the
  matrix A. K must satisfy  0 .le. K.

 ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

 A
  A is COMPLEX array of DIMENSION ( LDA, n ).

  Before entry with UPLO = 'U' or 'u', the leading ( k + 1 )
  by n part of the array A must contain the upper triangular
  band part of the hermitian matrix, supplied column by
  column, with the leading diagonal of the matrix in row
  ( k + 1 ) of the array, the first super-diagonal starting at
  position 2 in row k, and so on. The top left k by k triangle
  of the array A is not referenced.

  The following program segment will transfer the upper
  triangular part of a hermitian band matrix from conventional
  full matrix storage to band storage:

       DO 20, J = 1, N
          M = K + 1 - J
          DO 10, I = MAX( 1, J - K ), J
             A( M + I, J ) = matrix( I, J )
   10    CONTINUE
   20 CONTINUE
```

```
  Before entry with UPLO = 'L' or 'l', the leading ( k + 1 )
  by n part of the array A must contain the lower triangular
  band part of the hermitian matrix, supplied column by
  column, with the leading diagonal of the matrix in row 1 of
  the array, the first sub-diagonal starting at position 1 in
  row 2, and so on. The bottom right k by k triangle of the
  array A is not referenced.

  The following program segment will transfer the lower
  triangular part of a hermitian band matrix from conventional
  full matrix storage to band storage:

       DO 20, J = 1, N
          M = 1 - J
          DO 10, I = J, MIN( N, J + K )
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Note that the imaginary parts of the diagonal elements need
  not be set and are assumed to be zero.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( k + 1 ).

X
  X is COMPLEX array of DIMENSION at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta.

Y
  Y is COMPLEX array of DIMENSION at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the
  vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.
```

```
The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine chemv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           CHEMV

Function/Subroutine Documentation
   subroutine chemv (character UPLO, integer N, complex ALPHA, complex,
       dimension(lda,*) A, integer LDA, complex, dimension(*) X, integer INCX,
       complex BETA, complex, dimension(*) Y, integer INCY)
       CHEMV

Purpose:
   CHEMV  performs the matrix-vector  operation

      y := alpha*A*x + beta*y,

   where alpha and beta are scalars, x and y are n element vectors and
   A is an n by n hermitian matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A
   is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of A
   is to be referenced.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is COMPLEX
   On entry, ALPHA specifies the scalar alpha.

 A
   A is COMPLEX array of DIMENSION ( LDA, n ).
   Before entry with  UPLO = 'U' or 'u', the leading n by n
   upper triangular part of the array A must contain the upper
   triangular part of the hermitian matrix and the strictly
   lower triangular part of A is not referenced.

   Before entry with UPLO = 'L' or 'l', the leading n by n
   lower triangular part of the array A must contain the lower
```

```
  triangular part of the hermitian matrix and the strictly
  upper triangular part of A is not referenced.

  Note that the imaginary parts of the diagonal elements need
  not be set and are assumed to be zero.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

Y
  Y is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine cher (UPLO, N, ALPHA, X, INCX, A, LDA)
           CHER

Function/Subroutine Documentation
   subroutine cher (character UPLO, integer N, real ALPHA, complex,
       dimension(*) X, integer INCX, complex, dimension(lda,*) A, integer LDA)
       CHER
```

```
Purpose:
   CHER  performs the hermitian rank 1 operation

      A := alpha*x*x**H + A,

   where alpha is a real scalar, x is an n element vector and A is an
   n by n hermitian matrix.

Parameters:

   UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A
   is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of A
   is to be referenced.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 X
   X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
   Before entry, the incremented array X must contain the n
   element vector x.

 INCX
   INCX is INTEGER
   On entry, INCX specifies the increment for the elements of X.
   INCX must not be zero.

 A
   A is COMPLEX array of DIMENSION ( LDA, n ).

   Before entry with  UPLO = 'U' or 'u', the leading n by n
   upper triangular part of the array A must contain the upper
   triangular part of the hermitian matrix and the strictly
   lower triangular part of A is not referenced. On exit, the
   upper triangular part of the array A is overwritten by the
   upper triangular part of the updated matrix.
```

```
  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the hermitian matrix and the strictly
  upper triangular part of A is not referenced. On exit, the
  lower triangular part of the array A is overwritten by the
  lower triangular part of the updated matrix.

  Note that the imaginary parts of the diagonal elements need
  not be set, they are assumed to be zero, and on exit they
  are set to zero.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cher2 (UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
           CHER2

Function/Subroutine Documentation
   subroutine cher2 (character UPLO, integer N, complex ALPHA, complex,
       dimension(*) X, integer INCX, complex, dimension(*) Y, integer INCY,
       complex, dimension(lda,*) A, integer LDA)
       CHER2

Purpose:
   CHER2  performs the hermitian rank 2 operation

      A := alpha*x*y**H + conjg( alpha )*y*x**H + A,

   where alpha is a scalar, x and y are n element vectors and A is an n
   by n hermitian matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A
   is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of A
```

```
  is to be referenced.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

Y
  Y is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).

  Before entry with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the hermitian matrix and the strictly
  lower triangular part of A is not referenced. On exit, the
  upper triangular part of the array A is overwritten by the
  upper triangular part of the updated matrix.

  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the hermitian matrix and the strictly
  upper triangular part of A is not referenced. On exit, the
  lower triangular part of the array A is overwritten by the
  lower triangular part of the updated matrix.

  Note that the imaginary parts of the diagonal elements need
  not be set, they are assumed to be zero, and on exit they
```

```
  are set to zero.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine chpmv (UPLO, N, ALPHA, AP, X, INCX, BETA, Y, INCY)
           CHPMV

Function/Subroutine Documentation
   subroutine chpmv (character UPLO, integer N, complex ALPHA, complex,
       dimension(*) AP, complex, dimension(*) X, integer INCX, complex BETA,
       complex, dimension(*) Y, integer INCY)
       CHPMV

Purpose:
   CHPMV  performs the matrix-vector operation

     y := alpha*A*x + beta*y,

   where alpha and beta are scalars, x and y are n element vectors and
   A is an n by n hermitian matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the matrix A is supplied in the packed
   array AP as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is supplied in AP.

   UPLO = 'L' or 'l'   The lower triangular part of A is supplied in AP.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 ALPHA
   ALPHA is COMPLEX
   On entry, ALPHA specifies the scalar alpha.

 AP
   AP is COMPLEX array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

   Before entry with UPLO = 'U' or 'u', the array AP must
   contain the upper triangular part of the hermitian matrix
```

```
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 1, 2 )
  and a( 2, 2 ) respectively, and so on.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular part of the hermitian matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 )
  and a( 3, 1 ) respectively, and so on.

  Note that the imaginary parts of the diagonal elements need
  not be set and are assumed to be zero.

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.

Y
  Y is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine chpr (UPLO, N, ALPHA, X, INCX, AP)
           CHPR

Function/Subroutine Documentation
   subroutine chpr (character UPLO, integer N, real ALPHA, complex,
       dimension(*) X, integer INCX, complex, dimension(*) AP)
       CHPR

Purpose:
   CHPR    performs the hermitian rank 1 operation

      A := alpha*x*x**H + A,

   where alpha is a real scalar, x is an n element vector and A is an
   n by n hermitian matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the matrix A is supplied in the packed
   array AP as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is supplied in AP.

   UPLO = 'L' or 'l'   The lower triangular part of A is supplied in AP.

 N
   N is INTEGER
```

```
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

  AP
  AP is COMPLEX array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

  Before entry with  UPLO = 'U' or 'u', the array AP must
  contain the upper triangular part of the hermitian matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 1, 2 )
  and a( 2, 2 ) respectively, and so on. On exit, the array
  AP is overwritten by the upper triangular part of the
  updated matrix.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular part of the hermitian matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 )
  and a( 3, 1 ) respectively, and so on. On exit, the array
  AP is overwritten by the lower triangular part of the
  updated matrix.

  Note that the imaginary parts of the diagonal elements need
  not be set, they are assumed to be zero, and on exit they
  are set to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine chpr2 (UPLO, N, ALPHA, X, INCX, Y, INCY, AP)
           CHPR2

Function/Subroutine Documentation
   subroutine chpr2 (character UPLO, integer N, complex ALPHA, complex,
       dimension(*) X, integer INCX, complex, dimension(*) Y, integer INCY,
       complex, dimension(*) AP)
       CHPR2

Purpose:
   CHPR2  performs the hermitian rank 2 operation

   A := alpha*x*y**H + conjg( alpha )*y*x**H + A,

   where alpha is a scalar, x and y are n element vectors and A is an
   n by n hermitian matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the matrix A is supplied in the packed
   array AP as follows:

   UPLO = 'U' or 'u'   The upper triangular part of A is supplied in AP.

   UPLO = 'L' or 'l'   The lower triangular part of A is supplied in AP.
```

```
N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

Y
  Y is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of Y.
  INCY must not be zero.

AP
  AP is COMPLEX array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

  Before entry with  UPLO = 'U' or 'u', the array AP must
  contain the upper triangular part of the hermitian matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 1, 2 )
  and a( 2, 2 ) respectively, and so on. On exit, the array
  AP is overwritten by the upper triangular part of the updated matrix.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular part of the hermitian matrix
  packed sequentially, column by column, so that AP( 1 )
  contains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 )
  and a( 3, 1 ) respectively, and so on. On exit, the array
  AP is overwritten by the lower triangular part of the updated matrix.

  Note that the imaginary parts of the diagonal elements need
  not be set, they are assumed to be zero, and on exit they
  are set to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctbmv (UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
           CTBMV

Function/Subroutine Documentation
   subroutine ctbmv (character UPLO, character TRANS, character DIAG, integer
       N, integer K, complex, dimension(lda,*) A, integer LDA, complex,
       dimension(*) X, integer INCX)
       CTBMV

Purpose:
   CTBMV  performs one of the matrix-vector operations

   x := A*x,   or   x := A**T*x,   or   x := A**H*x,

   where x is an n element vector and  A is an n by n unit, or non-unit,
   upper or lower triangular band matrix, with ( k + 1 ) diagonals.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:
```

```
  UPLO = 'U' or 'u'   A is an upper triangular matrix.

  UPLO = 'L' or 'l'   A is a lower triangular matrix.

TRANS
  TRANS is CHARACTER*1
  On entry, TRANS specifies the operation to be performed as follows:

  TRANS = 'N' or 'n'   x := A*x.

  TRANS = 'T' or 't'   x := A**T*x.

  TRANS = 'C' or 'c'   x := A**H*x.

DIAG
  DIAG is CHARACTER*1
  On entry, DIAG specifies whether or not A is unit triangular as follows:

  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

K
  K is INTEGER
  On entry with UPLO = 'U' or 'u', K specifies the number of
  super-diagonals of the matrix A.
  On entry with UPLO = 'L' or 'l', K specifies the number of
  sub-diagonals of the matrix A.
  K must satisfy  0 .le. K.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).

  Before entry with UPLO = 'U' or 'u', the leading ( k + 1 )
  by n part of the array A must contain the upper triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row
  ( k + 1 ) of the array, the first super-diagonal starting at
  position 2 in row k, and so on. The top left k by k triangle
  of the array A is not referenced.

  The following program segment will transfer an upper
  triangular band matrix from conventional full matrix storage
  to band storage:
```

```
      DO 20, J = 1, N
         M = K + 1 - J
         DO 10, I = MAX( 1, J - K ), J
            A( M + I, J ) = matrix( I, J )
   10    CONTINUE
   20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced.

The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
         M = 1 - J
         DO 10, I = J, MIN( N, J + K )
            A( M + I, J ) = matrix( I, J )
   10    CONTINUE
   20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

LDA

LDA is INTEGER
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (k + 1).

X

X is COMPLEX array of dimension at least (1 + (n - 1)*abs(INCX)).
Before entry, the incremented array X must contain the n element vector x. On exit, X is overwritten with the tranformed vector x.

INCX

INCX is INTEGER
On entry, INCX specifies the increment for the elements of X. INCX must not be zero.

The vector and matrix arguments are not referenced when N = 0, or M = 0

SYNOPSIS
   Functions/Subroutines
       subroutine ctbsv (UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX)
           CTBSV

Function/Subroutine Documentation
   subroutine ctbsv (character UPLO, character TRANS, character DIAG, integer
       N, integer K, complex, dimension(lda,*) A, integer LDA, complex,
       dimension(*) X, integer INCX)
       CTBSV

Purpose:
   CTBSV  solves one of the systems of equations

   A*x = b,   or   A**T*x = b,   or   A**H*x = b,

   where b and x are n element vectors and A is an n by n unit, or
   non-unit, upper or lower triangular band matrix, with ( k + 1 )
   diagonals.

   No test for singularity or near-singularity is included in this
   routine. Such tests must be performed before calling this routine.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the equations to be solved as follows:

   TRANS = 'N' or 'n'   A*x = b.

   TRANS = 'T' or 't'   A**T*x = b.

   TRANS = 'C' or 'c'   A**H*x = b.

 DIAG
   DIAG is CHARACTER*1
```

```
  On entry, DIAG specifies whether or not A is unit
  triangular as follows:

  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

K
  K is INTEGER
  On entry with UPLO = 'U' or 'u', K specifies the number of
  super-diagonals of the matrix A.
  On entry with UPLO = 'L' or 'l', K specifies the number of
  sub-diagonals of the matrix A.
  K must satisfy  0 .le. K.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).

  Before entry with UPLO = 'U' or 'u', the leading ( k + 1 )
  by n part of the array A must contain the upper triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row
  ( k + 1 ) of the array, the first super-diagonal starting at
  position 2 in row k, and so on. The top left k by k triangle
  of the array A is not referenced.

  The following program segment will transfer an upper
  triangular band matrix from conventional full matrix storage
  to band storage:

       DO 20, J = 1, N
          M = K + 1 - J
          DO 10, I = MAX( 1, J - K ), J
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Before entry with UPLO = 'L' or 'l', the leading ( k + 1 )
  by n part of the array A must contain the lower triangular
  band part of the matrix of coefficients, supplied column by
  column, with the leading diagonal of the matrix in row 1 of
  the array, the first sub-diagonal starting at position 1 in
  row 2, and so on. The bottom right k by k triangle of the
  array A is not referenced.
```

```
  The following program segment will transfer a lower
  triangular band matrix from conventional full matrix storage
  to band storage:

       DO 20, J = 1, N
          M = 1 - J
          DO 10, I = J, MIN( N, J + K )
             A( M + I, J ) = matrix( I, J )
    10    CONTINUE
    20 CONTINUE

  Note that when DIAG = 'U' or 'u' the elements of the array A
  corresponding to the diagonal elements of the matrix are not
  referenced, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least ( k + 1 ).

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctpmv (UPLO, TRANS, DIAG, N, AP, X, INCX)
           CTPMV

Function/Subroutine Documentation
   subroutine ctpmv (character UPLO, character TRANS, character DIAG, integer
       N, complex, dimension(*) AP, complex, dimension(*) X, integer INCX)
       CTPMV

Purpose:
   CTPMV  performs one of the matrix-vector operations

   x := A*x,   or   x := A**T*x,   or   x := A**H*x,

   where x is an n element vector and  A is an n by n unit, or non-unit,
```

```
  upper or lower triangular matrix, supplied in packed form.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   x := A*x.

   TRANS = 'T' or 't'   x := A**T*x.

   TRANS = 'C' or 'c'   x := A**H*x.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 AP
   AP is COMPLEX array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

   Before entry with  UPLO = 'U' or 'u', the array AP must
   contain the upper triangular matrix packed sequentially,
   column by column, so that AP( 1 ) contains a( 1, 1 ),
   AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
   respectively, and so on.

   Before entry with UPLO = 'L' or 'l', the array AP must
   contain the lower triangular matrix packed sequentially,
   column by column, so that AP( 1 ) contains a( 1, 1 ),
   AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 )
```

```
  respectively, and so on.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced, but are assumed to be unity.

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x. On exit, X is overwritten with the
  tranformed vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctpsv (UPLO, TRANS, DIAG, N, AP, X, INCX)
           CTPSV

Function/Subroutine Documentation
   subroutine ctpsv (character UPLO, character TRANS, character DIAG, integer
       N, complex, dimension(*) AP, complex, dimension(*) X, integer INCX)
       CTPSV

 Purpose:
   CTPSV  solves one of the systems of equations

   A*x = b,   or   A**T*x = b,   or   A**H*x = b,
```

```
   where b and x are n element vectors and A is an n by n unit, or
   non-unit, upper or lower triangular matrix, supplied in packed form.

   No test for singularity or near-singularity is included in this
   routine. Such tests must be performed before calling this routine.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS

   TRANS is CHARACTER*1
   On entry, TRANS specifies the equations to be solved as follows:

   TRANS = 'N' or 'n'   A*x = b.

   TRANS = 'T' or 't'   A**T*x = b.

   TRANS = 'C' or 'c'   A**H*x = b.

 DIAG

   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

   DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.

 AP
   AP is COMPLEX array of DIMENSION at least ( ( n*( n + 1 ) )/2 ).

   Before entry with  UPLO = 'U' or 'u', the array AP must
   contain the upper triangular matrix packed sequentially,
   column by column, so that AP( 1 ) contains a( 1, 1 ),
```

```
  AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
  respectively, and so on.

  Before entry with UPLO = 'L' or 'l', the array AP must
  contain the lower triangular matrix packed sequentially,
  column by column, so that AP( 1 ) contains a( 1, 1 ),
  AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 )
  respectively, and so on.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced, but are assumed to be unity.

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctrmv (UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
           CTRMV

Function/Subroutine Documentation
   subroutine ctrmv (character UPLO, character TRANS, character DIAG, integer
       N, complex, dimension(lda,*) A, integer LDA, complex, dimension(*) X,
       integer INCX)
       CTRMV

Purpose:
   CTRMV  performs one of the matrix-vector operations

   x := A*x,   or   x := A**T*x,   or   x := A**H*x,

   where x is an n element vector and  A is an n by n unit, or non-unit,
   upper or lower triangular matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS

   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   x := A*x.

   TRANS = 'T' or 't'   x := A**T*x.

   TRANS = 'C' or 'c'   x := A**H*x.

 DIAG

   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:
```

```
  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).
  Before entry with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular matrix and the strictly lower triangular part of
  A is not referenced.

  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular matrix and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced either, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element vector x. On exit, X is overwritten with the
  tranformed vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.

  The vector and matrix arguments are not referenced when N = 0, or M = 0
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctrsv (UPLO, TRANS, DIAG, N, A, LDA, X, INCX)
           CTRSV

Function/Subroutine Documentation
   subroutine ctrsv (character UPLO, character TRANS, character DIAG, integer
```

```
      N, complex, dimension(lda,*) A, integer LDA, complex, dimension(*) X,
      integer INCX)
      CTRSV

Purpose:
   CTRSV  solves one of the systems of equations

   A*x = b,   or   A**T*x = b,   or   A**H*x = b,

   where b and x are n element vectors and A is an n by n unit, or
   non-unit, upper or lower triangular matrix.

   No test for singularity or near-singularity is included in this
   routine. Such tests must be performed before calling this routine.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the equations to be solved as follows:

   TRANS = 'N' or 'n'   A*x = b.

   TRANS = 'T' or 't'   A**T*x = b.

   TRANS = 'C' or 'c'   A**H*x = b.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit
   triangular as follows:

 DIAG = 'U' or 'u'   A is assumed to be unit triangular.

   DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.
```

```
A
                    A is COMPLEX array of DIMENSION ( LDA, n ).

  Before entry with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular matrix and the strictly lower triangular part of
  A is not referenced.

  Before entry with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular matrix and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u', the diagonal elements of
  A are not referenced either, but are assumed to be unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).

X
  X is COMPLEX array of dimension at least ( 1 + ( n - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the n
  element right-hand side vector b. On exit, X is overwritten
  with the solution vector x.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of X.
  INCX must not be zero.
```

 NAME
      ZGBMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or   y :=
      alpha*conjg( A' )*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZGBMV ( TRANS, M, N, KL, KU, ALPHA, A, LDA, X,
                         INCX, BETA, Y, INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, KL, KU, LDA, M, N

          CHARACTER*1  TRANS

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZGBMV  performs one of the matrix-vector operations

      where alpha and beta are scalars, x and y are vectors and A
      is an m by n band matrix, with kl sub-diagonals and ku
      super-diagonals.

 PARAMETERS
      TRANS  - CHARACTER*1.
             On entry, TRANS specifies the operation to be per-
             formed as follows:

             TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

             TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.

             TRANS = 'C' or 'c'   y := alpha*conjg( A' )*x +
             beta*y.

             Unchanged on exit.

      M      - INTEGER.
             On entry, M specifies the number of rows of the
             matrix A.  M must be at least zero.  Unchanged on
             exit.

      N      - INTEGER.
             On entry, N specifies the number of columns of the
```

```
        matrix A.  N must be at least zero.  Unchanged on
        exit.

KL      - INTEGER.
        On entry, KL specifies the number of sub-diagonals of
        the matrix A. KL must satisfy  0 .le. KL.  Unchanged

        on exit.

KU      - INTEGER.
        On entry, KU specifies the number of super-diagonals
        of the matrix A. KU must satisfy  0 .le. KU.
        Unchanged on exit.

ALPHA   - COMPLEX*16      .
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

A       - COMPLEX*16       array of DIMENSION ( LDA, n ).
        Before entry, the leading ( kl + ku + 1 ) by n part
        of the array A must contain the matrix of coeffi-
        cients, supplied column by column, with the leading
        diagonal of the matrix in row ( ku + 1 ) of the
        array, the first super-diagonal starting at position
        2 in row ku, the first sub-diagonal starting at posi-
        tion 1 in row ( ku + 2 ), and so on.  Elements in the
        array A that do not correspond to elements in the
        band matrix (such as the top left ku by ku triangle)
        are not referenced.  The following program segment
        will transfer a band matrix from conventional full
        matrix storage to band storage:

        DO 20, J = 1, N K = KU + 1 - J DO 10, I = MAX( 1, J -
        KU ), MIN( M, J + KL ) A( K + I, J ) = matrix( I, J )
        10    CONTINUE 20 CONTINUE

        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least ( kl + ku + 1 ).  Unchanged on exit.

X       - COMPLEX*16       array of DIMENSION at least
        ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
        and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
        Before entry, the incremented array X must contain
        the vector x.  Unchanged on exit.

INCX    - INTEGER.
```

```
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.

      BETA   - COMPLEX*16      .
             On entry, BETA specifies the scalar beta. When BETA
             is supplied as zero then Y need not be set on input.
             Unchanged on exit.

      Y      - COMPLEX*16       array of DIMENSION at least
             ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
             and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
             Before entry, the incremented array Y must contain
             the vector y. On exit, Y is overwritten by the
             updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.
```

 NAME
      ZGEMV - perform one of the matrix-vector operations   y :=
      alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or   y :=
      alpha*conjg( A' )*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZGEMV ( TRANS, M, N, ALPHA, A, LDA, X, INCX,
                         BETA, Y, INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, LDA, M, N

          CHARACTER*1  TRANS

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZGEMV  performs one of the matrix-vector operations

      where alpha and beta are scalars, x and y are vectors and A
      is an m by n matrix.

 PARAMETERS
      TRANS  - CHARACTER*1.
             On entry, TRANS specifies the operation to be per-
             formed as follows:

             TRANS = 'N' or 'n'   y := alpha*A*x + beta*y.

             TRANS = 'T' or 't'   y := alpha*A'*x + beta*y.
```

```
        TRANS = 'C' or 'c'   y := alpha*conjg( A' )*x +
        beta*y.

        Unchanged on exit.

M       - INTEGER.
        On entry, M specifies the number of rows of the
        matrix A.  M must be at least zero.  Unchanged on
        exit.

N       - INTEGER.
        On entry, N specifies the number of columns of the
        matrix A.  N must be at least zero.  Unchanged on
        exit.

ALPHA   - COMPLEX*16      .
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

A       - COMPLEX*16       array of DIMENSION ( LDA, n ).
        Before entry, the leading m by n part of the array A
        must contain the matrix of coefficients.  Unchanged
        on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least max( 1, m ).  Unchanged on exit.

X       - COMPLEX*16       array of DIMENSION at least
        ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
        and at least ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
        Before entry, the incremented array X must contain
        the vector x.  Unchanged on exit.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
        exit.

BETA    - COMPLEX*16      .
        On entry, BETA specifies the scalar beta. When BETA
        is supplied as zero then Y need not be set on input.
        Unchanged on exit.

Y       - COMPLEX*16       array of DIMENSION at least
        ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
        and at least ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
        Before entry with BETA non-zero, the incremented
        array Y must contain the vector y. On exit, Y is
```

```
             overwritten by the updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.

             ———-

 NAME
      ZGERC - perform the rank 1 operation
              A := alpha*x*conjg( y' ) + A,

 SYNOPSIS
      SUBROUTINE ZGERC ( M, N, ALPHA, X, INCX, Y, INCY, A, LDA )

          COMPLEX*16   ALPHA

          INTEGER      INCX, INCY, LDA, M, N

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZGERC  performs the rank 1 operation

      where alpha is a scalar, x is an m element vector, y is an n
      element vector and A is an m by n matrix.

 PARAMETERS
      M      - INTEGER.
             On entry, M specifies the number of rows of the
             matrix A.  M must be at least zero.  Unchanged on
             exit.

      N      - INTEGER.
             On entry, N specifies the number of columns of the
             matrix A.  N must be at least zero.  Unchanged on
             exit.

      ALPHA  - COMPLEX*16      .
```

```
          On entry, ALPHA specifies the scalar alpha.
          Unchanged on exit.

     X    - COMPLEX*16       array of dimension at least
          ( 1 + ( m - 1 )*abs( INCX ) ).  Before entry, the
          incremented array X must contain the m element vector
          x.  Unchanged on exit.

     INCX - INTEGER.
          On entry, INCX specifies the increment for the ele-
          ments of X. INCX must not be zero.  Unchanged on
          exit.

     Y    - COMPLEX*16       array of dimension at least
          ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
          incremented array Y must contain the n element vector
          y.  Unchanged on exit.

     INCY - INTEGER.
          On entry, INCY specifies the increment for the

          elements of Y. INCY must not be zero.  Unchanged on
          exit.

     A    - COMPLEX*16       array of DIMENSION ( LDA, n ).
          Before entry, the leading m by n part of the array A
          must contain the matrix of coefficients. On exit, A
          is overwritten by the updated matrix.

     LDA  - INTEGER.
          On entry, LDA specifies the first dimension of A as
          declared in the calling (sub) program. LDA must be at
          least max( 1, m ).  Unchanged on exit.

 NAME
      ZGERU - perform the rank 1 operation   A := alpha*x*y' + A,

 SYNOPSIS
      SUBROUTINE ZGERU ( M, N, ALPHA, X, INCX, Y, INCY, A, LDA )

          COMPLEX*16   ALPHA

          INTEGER      INCX, INCY, LDA, M, N

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZGERU  performs the rank 1 operation

      where alpha is a scalar, x is an m element vector, y is an n
      element vector and A is an m by n matrix.

 PARAMETERS
      M      - INTEGER.
               On entry, M specifies the number of rows of the
               matrix A.  M must be at least zero.  Unchanged on
               exit.

      N      - INTEGER.
               On entry, N specifies the number of columns of the
               matrix A.  N must be at least zero.  Unchanged on
               exit.

      ALPHA  - COMPLEX*16      .
               On entry, ALPHA specifies the scalar alpha.
               Unchanged on exit.

      X      - COMPLEX*16       array of dimension at least
               ( 1 + ( m - 1 )*abs( INCX ) ).  Before entry, the
               incremented array X must contain the m element vector
               x.  Unchanged on exit.

      INCX   - INTEGER.
               On entry, INCX specifies the increment for the ele-
               ments of X. INCX must not be zero.  Unchanged on
               exit.

      Y      - COMPLEX*16       array of dimension at least
               ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
```

```
            incremented array Y must contain the n element vector
            y.  Unchanged on exit.

      INCY   - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on

            exit.

      A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
            Before entry, the leading m by n part of the array A
            must contain the matrix of coefficients. On exit, A
            is overwritten by the updated matrix.

      LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, m ).  Unchanged on exit.
```

 NAME
      ZHBMV - perform the matrix-vector operation
              y := alpha*A*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZHBMV ( UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA,
                         Y, INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, K, LDA, N

          CHARACTER*1  UPLO

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )
```

```
PURPOSE
     ZHBMV  performs the matrix-vector  operation

     where alpha and beta are scalars, x and y are n element vec-
     tors and A is an n by n hermitian band matrix, with k
     super-diagonals.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the upper or lower
              triangular part of the band matrix A is being sup-
              plied as follows:

              UPLO = 'U' or 'u'   The upper triangular part of A is
              being supplied.

              UPLO = 'L' or 'l'   The lower triangular part of A is
              being supplied.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     K      - INTEGER.
              On entry, K specifies the number of super-diagonals
              of the matrix A. K must satisfy  0 .le. K.  Unchanged
              on exit.

     ALPHA  - COMPLEX*16      .
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).

              Before entry with UPLO = 'U' or 'u', the leading ( k
              + 1 ) by n part of the array A must contain the upper
              triangular band part of the hermitian matrix, sup-
              plied column by column, with the leading diagonal of
              the matrix in row ( k + 1 ) of the array, the first
              super-diagonal starting at position 2 in row k, and
              so on. The top left k by k triangle of the array A is
              not referenced.  The following program segment will
              transfer the upper triangular part of a hermitian
              band matrix from conventional full matrix storage to
              band storage:

              DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
              K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
```

```
        20 CONTINUE

        Before entry with UPLO = 'L' or 'l', the leading ( k
        + 1 ) by n part of the array A must contain the lower
        triangular band part of the hermitian matrix, sup-
        plied column by column, with the leading diagonal of
        the matrix in row 1 of the array, the first sub-
        diagonal starting at position 1 in row 2, and so on.
        The bottom right k by k triangle of the array A is
        not referenced.  The following program segment will
        transfer the lower triangular part of a hermitian
        band matrix from conventional full matrix storage to
        band storage:

        DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
        ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
        CONTINUE

        Note that the imaginary parts of the diagonal ele-
        ments need not be set and are assumed to be zero.
        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program. LDA must be at
        least ( k + 1 ).  Unchanged on exit.

X       - COMPLEX*16       array of DIMENSION at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the vector x.
        Unchanged on exit.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
        exit.

BETA    - COMPLEX*16      .

        On entry, BETA specifies the scalar beta.  Unchanged
        on exit.

Y       - COMPLEX*16       array of DIMENSION at least
        ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
        incremented array Y must contain the vector y. On
        exit, Y is overwritten by the updated vector y.

INCY    - INTEGER.
        On entry, INCY specifies the increment for the ele-
        ments of Y. INCY must not be zero.  Unchanged on
```

```
exit.
```

 NAME
      ZHEMV - perform the matrix-vector operation
              y := alpha*A*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZHEMV ( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y,
                         INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, LDA, N

          CHARACTER*1  UPLO

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )

 PURPOSE
      ZHEMV  performs the matrix-vector  operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n hermitian matrix.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the upper or lower
             triangular part of the array A is to be referenced as
             follows:
```

```
         UPLO = 'U' or 'u'   Only the upper triangular part of
         A is to be referenced.

         UPLO = 'L' or 'l'   Only the lower triangular part of
         A is to be referenced.

         Unchanged on exit.

N        - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

ALPHA    - COMPLEX*16      .
         On entry, ALPHA specifies the scalar alpha.
         Unchanged on exit.

A        - COMPLEX*16       array of DIMENSION ( LDA, n ).
         Before entry with  UPLO = 'U' or 'u', the leading n
         by n upper triangular part of the array A must con-
         tain the upper triangular part of the hermitian
         matrix and the strictly lower triangular part of A is
         not referenced.  Before entry with UPLO = 'L' or 'l',
         the leading n by n lower triangular part of the array

         A must contain the lower triangular part of the her-
         mitian matrix and the strictly upper triangular part
         of A is not referenced.  Note that the imaginary
         parts of the diagonal elements need not be set and
         are assumed to be zero.  Unchanged on exit.

LDA      - INTEGER.
         On entry, LDA specifies the first dimension of A as
         declared in the calling (sub) program. LDA must be at
         least max( 1, n ).  Unchanged on exit.

X        - COMPLEX*16       array of dimension at least
         ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
         incremented array X must contain the n element vector
         x.  Unchanged on exit.

INCX     - INTEGER.
         On entry, INCX specifies the increment for the ele-
         ments of X. INCX must not be zero.  Unchanged on
         exit.

BETA     - COMPLEX*16      .
         On entry, BETA specifies the scalar beta. When BETA
         is supplied as zero then Y need not be set on input.
         Unchanged on exit.
```

```
Y      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
       incremented array Y must contain the n element vector
       y. On exit, Y is overwritten by the updated vector y.

INCY   - INTEGER.
       On entry, INCY specifies the increment for the ele-
       ments of Y. INCY must not be zero.  Unchanged on
       exit.
```

 NAME
      ZHER - perform the hermitian rank 1 operation
             A := alpha*x*conjg( x' ) + A,

 SYNOPSIS
      SUBROUTINE ZHER ( UPLO, N, ALPHA, X, INCX, A, LDA )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, LDA, N
```

```
         CHARACTER*1 UPLO

         COMPLEX*16  A( LDA, * ), X( * )

PURPOSE
     ZHER   performs the hermitian rank 1 operation

     where alpha is a real scalar, x is an n element vector and A
     is an n by n hermitian matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the upper or lower
              triangular part of the array A is to be referenced as
              follows:

              UPLO = 'U' or 'u'   Only the upper triangular part of
              A is to be referenced.

              UPLO = 'L' or 'l'   Only the lower triangular part of
              A is to be referenced.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
              ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
              incremented array X must contain the n element vector
              x.  Unchanged on exit.

     INCX   - INTEGER.
              On entry, INCX specifies the increment for the ele-
              ments of X. INCX must not be zero.  Unchanged on

              exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
              Before entry with  UPLO = 'U' or 'u', the leading n
              by n upper triangular part of the array A must con-
              tain the upper triangular part of the hermitian
              matrix and the strictly lower triangular part of A is
              not referenced. On exit, the upper triangular part of
```

```
             the array A is overwritten by the upper triangular
             part of the updated matrix.  Before entry with UPLO =
             'L' or 'l', the leading n by n lower triangular part
             of the array A must contain the lower triangular part
             of the hermitian matrix and the strictly upper tri-
             angular part of A is not referenced. On exit, the
             lower triangular part of the array A is overwritten
             by the lower triangular part of the updated matrix.
             Note that the imaginary parts of the diagonal ele-
             ments need not be set, they are assumed to be zero,
             and on exit they are set to zero.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least max( 1, n ).  Unchanged on exit.
```

 NAME
      ZHER2 - perform the hermitian rank 2 operation
      A := alpha*x*conjg( y' ) + conjg( alpha )*y*conjg( x' ) + A,

 SYNOPSIS
      SUBROUTINE ZHER2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA
                       )

          COMPLEX*16   ALPHA

          INTEGER      INCX, INCY, LDA, N

          CHARACTER*1  UPLO

          COMPLEX*16   A( LDA, * ), X( * ), Y( * )
```

```
PURPOSE
     ZHER2  performs the hermitian rank 2 operation

     where alpha is a scalar, x and y are n element vectors and A
     is an n by n hermitian matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the upper or lower
              triangular part of the array A is to be referenced as
              follows:

              UPLO = 'U' or 'u'   Only the upper triangular part of
              A is to be referenced.

              UPLO = 'L' or 'l'   Only the lower triangular part of
              A is to be referenced.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
              ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
              incremented array X must contain the n element vector
              x.  Unchanged on exit.

     INCX   - INTEGER.
              On entry, INCX specifies the increment for the

              elements of X. INCX must not be zero.  Unchanged on
              exit.

     Y      - COMPLEX*16       array of dimension at least
              ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
              incremented array Y must contain the n element vector
              y.  Unchanged on exit.

     INCY   - INTEGER.
              On entry, INCY specifies the increment for the ele-
              ments of Y. INCY must not be zero.  Unchanged on
              exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
```

```
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular part of the hermitian
            matrix and the strictly lower triangular part of A is
            not referenced. On exit, the upper triangular part of
            the array A is overwritten by the upper triangular
            part of the updated matrix.  Before entry with UPLO =
            'L' or 'l', the leading n by n lower triangular part
            of the array A must contain the lower triangular part
            of the hermitian matrix and the strictly upper tri-
            angular part of A is not referenced. On exit, the
            lower triangular part of the array A is overwritten
            by the lower triangular part of the updated matrix.
            Note that the imaginary parts of the diagonal ele-
            ments need not be set, they are assumed to be zero,
            and on exit they are set to zero.

      LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, n ).  Unchanged on exit.

 NAME
      ZHPMV - perform the matrix-vector operation
              y := alpha*A*x + beta*y,

 SYNOPSIS
      SUBROUTINE ZHPMV ( UPLO, N, ALPHA, AP, X, INCX, BETA, Y,
                         INCY )

          COMPLEX*16   ALPHA, BETA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO

          COMPLEX*16   AP( * ), X( * ), Y( * )

 PURPOSE
      ZHPMV  performs the matrix-vector operation

      where alpha and beta are scalars, x and y are n element vec-
      tors and A is an n by n hermitian matrix, supplied in packed
      form.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the upper or lower
             triangular part of the matrix A is supplied in the
             packed array AP as follows:
```

```
        UPLO = 'U' or 'u'   The upper triangular part of A is
        supplied in AP.

        UPLO = 'L' or 'l'   The lower triangular part of A is
        supplied in AP.

        Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the order of the matrix A.  N
        must be at least zero.  Unchanged on exit.

ALPHA   - COMPLEX*16      .
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

AP      - COMPLEX*16       array of DIMENSION at least
        ( ( n*( n + 1 ) )/2 ).  Before entry with UPLO = 'U'
        or 'u', the array AP must contain the upper triangu-
        lar part of the hermitian matrix packed sequentially,
        column by column, so that AP( 1 ) contains a( 1, 1 ),
        AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )

        respectively, and so on.  Before entry with UPLO =
        'L' or 'l', the array AP must contain the lower tri-
        angular part of the hermitian matrix packed sequen-
        tially, column by column, so that AP( 1 ) contains a(
        1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1 ) and a(
        3, 1 ) respectively, and so on.  Note that the ima-
        ginary parts of the diagonal elements need not be set
        and are assumed to be zero.  Unchanged on exit.

X       - COMPLEX*16       array of dimension at least
        ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
        incremented array X must contain the n element vector
        x.  Unchanged on exit.

INCX    - INTEGER.
        On entry, INCX specifies the increment for the ele-
        ments of X. INCX must not be zero.  Unchanged on
        exit.

BETA    - COMPLEX*16      .
        On entry, BETA specifies the scalar beta. When BETA
        is supplied as zero then Y need not be set on input.
        Unchanged on exit.

Y       - COMPLEX*16       array of dimension at least
        ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
        incremented array Y must contain the n element vector
```

```
            y. On exit, Y is overwritten by the updated vector y.

      INCY   - INTEGER.
             On entry, INCY specifies the increment for the ele-
             ments of Y. INCY must not be zero.  Unchanged on
             exit.
```

 NAME
      ZHPR - perform the hermitian rank 1 operation
             A := alpha*x*conjg( x' ) + A,

 SYNOPSIS
      SUBROUTINE ZHPR ( UPLO, N, ALPHA, X, INCX, AP )

          DOUBLE      PRECISION ALPHA

          INTEGER     INCX, N

          CHARACTER*1 UPLO

          COMPLEX*16  AP( * ), X( * )

 PURPOSE
      ZHPR    performs the hermitian rank 1 operation

      where alpha is a real scalar, x is an n element vector and A
      is an n by n hermitian matrix, supplied in packed form.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On entry, UPLO specifies whether the upper or lower
             triangular part of the matrix A is supplied in the
             packed array AP as follows:

             UPLO = 'U' or 'u'   The upper triangular part of A is
             supplied in AP.

             UPLO = 'L' or 'l'   The lower triangular part of A is
             supplied in AP.

             Unchanged on exit.
```

```
N      - INTEGER.
       On entry, N specifies the order of the matrix A.  N
       must be at least zero.  Unchanged on exit.

ALPHA  - DOUBLE PRECISION.
       On entry, ALPHA specifies the scalar alpha.
       Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
       incremented array X must contain the n element vector
       x.  Unchanged on exit.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on

       exit.

AP     - COMPLEX*16       array of DIMENSION at least
       ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
       or 'u', the array AP must contain the upper triangu-
       lar part of the hermitian matrix packed sequentially,
       column by column, so that AP( 1 ) contains a( 1, 1 ),
       AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
       respectively, and so on. On exit, the array AP is
       overwritten by the upper triangular part of the
       updated matrix.  Before entry with UPLO = 'L' or 'l',
       the array AP must contain the lower triangular part
       of the hermitian matrix packed sequentially, column
       by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
       ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
       tively, and so on. On exit, the array AP is overwrit-
       ten by the lower triangular part of the updated
       matrix.  Note that the imaginary parts of the diago-
       nal elements need not be set, they are assumed to be
       zero, and on exit they are set to zero.

 NAME
      ZHPR2 - perform the hermitian rank 2 operation
      A := alpha*x*conjg( y' ) + conjg( alpha )*y*conjg( x' ) + A,

 SYNOPSIS
      SUBROUTINE ZHPR2 ( UPLO, N, ALPHA, X, INCX, Y, INCY, AP )

          COMPLEX*16   ALPHA

          INTEGER      INCX, INCY, N

          CHARACTER*1  UPLO
```

```
         COMPLEX*16   AP( * ), X( * ), Y( * )

PURPOSE
     ZHPR2  performs the hermitian rank 2 operation

     where alpha is a scalar, x and y are n element vectors and A
     is an n by n hermitian matrix, supplied in packed form.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the upper or lower
            triangular part of the matrix A is supplied in the
            packed array AP as follows:

            UPLO = 'U' or 'u'   The upper triangular part of A is
            supplied in AP.

            UPLO = 'L' or 'l'   The lower triangular part of A is
            supplied in AP.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

     X      - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x.  Unchanged on exit.

     INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on

            exit.

     Y      - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry, the
            incremented array Y must contain the n element vector
            y.  Unchanged on exit.

     INCY   - INTEGER.
            On entry, INCY specifies the increment for the ele-
            ments of Y. INCY must not be zero.  Unchanged on
```

```
            exit.

      AP     - COMPLEX*16       array of DIMENSION at least
             ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
             or 'u', the array AP must contain the upper triangu-
             lar part of the hermitian matrix packed sequentially,
             column by column, so that AP( 1 ) contains a( 1, 1 ),
             AP( 2 ) and AP( 3 ) contain a( 1, 2 ) and a( 2, 2 )
             respectively, and so on. On exit, the array AP is
             overwritten by the upper triangular part of the
             updated matrix.  Before entry with UPLO = 'L' or 'l',
             the array AP must contain the lower triangular part
             of the hermitian matrix packed sequentially, column
             by column, so that AP( 1 ) contains a( 1, 1 ), AP( 2
             ) and AP( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
             tively, and so on. On exit, the array AP is overwrit-
             ten by the lower triangular part of the updated
             matrix.  Note that the imaginary parts of the diago-
             nal elements need not be set, they are assumed to be
             zero, and on exit they are set to zero.
