NAME
     ZTBMV - perform one of the matrix-vector operations
     x := A*x, or x := A'*x, or x := conjg( A' )*x,

SYNOPSIS
     SUBROUTINE ZTBMV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                      )

         INTEGER      INCX, K, LDA, N

         CHARACTER*1  DIAG, TRANS, UPLO

         COMPLEX*16   A( LDA, * ), X( * )

PURPOSE
     ZTBMV  performs one of the matrix-vector operations

     where x is an n element vector and  A is an n by n unit, or
     non-unit, upper or lower triangular band matrix, with ( k +
     1 ) diagonals.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   x := A*x.

            TRANS = 'T' or 't'   x := A'*x.

            TRANS = 'C' or 'c'   x := conjg( A' )*x.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.
```

```
         DIAG = 'N' or 'n'   A is not assumed to be unit tri-
         angular.

         Unchanged on exit.

N        - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

K        - INTEGER.
         On entry with UPLO = 'U' or 'u', K specifies the
         number of super-diagonals of the matrix A.  On entry
         with UPLO = 'L' or 'l', K specifies the number of
         sub-diagonals of the matrix A.  K must satisfy  0
         .le. K.  Unchanged on exit.

A        - COMPLEX*16       array of DIMENSION ( LDA, n ).
         Before entry with UPLO = 'U' or 'u', the leading ( k
         + 1 ) by n part of the array A must contain the upper
         triangular band part of the matrix of coefficients,
         supplied column by column, with the leading diagonal
         of the matrix in row ( k + 1 ) of the array, the
         first super-diagonal starting at position 2 in row k,
         and so on. The top left k by k triangle of the array
         A is not referenced.  The following program segment
         will transfer an upper triangular band matrix from
         conventional full matrix storage to band storage:

         DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
         K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
         20 CONTINUE

         Before entry with UPLO = 'L' or 'l', the leading ( k
         + 1 ) by n part of the array A must contain the lower
         triangular band part of the matrix of coefficients,
         supplied column by column, with the leading diagonal
         of the matrix in row 1 of the array, the first sub-
         diagonal starting at position 1 in row 2, and so on.
         The bottom right k by k triangle of the array A is
         not referenced.  The following program segment will
         transfer a lower triangular band matrix from conven-
         tional full matrix storage to band storage:

         DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
         ) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
         CONTINUE

         Note that when DIAG = 'U' or 'u' the elements of the
         array A corresponding to the diagonal elements of the
```

```
            matrix are not referenced, but are assumed to be
            unity.  Unchanged on exit.

      LDA    - INTEGER.
             On entry, LDA specifies the first dimension of A as
             declared in the calling (sub) program. LDA must be at
             least ( k + 1 ).  Unchanged on exit.

      X      - COMPLEX*16       array of dimension at least
             ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
             incremented array X must contain the n element vector
             x. On exit, X is overwritten with the transformed
             vector x.

      INCX   - INTEGER.
             On entry, INCX specifies the increment for the ele-
             ments of X. INCX must not be zero.  Unchanged on
             exit.
```

 NAME
      ZTBSV - solve one of the systems of equations
      A*x = b, or A'*x = b, or conjg( A' )*x = b,

 SYNOPSIS
      SUBROUTINE ZTBSV ( UPLO, TRANS, DIAG, N, K, A, LDA, X, INCX
                       )

          INTEGER      INCX, K, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   A( LDA, * ), X( * )

 PURPOSE
      ZTBSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular band matrix, with ( k
      + 1 ) diagonals.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
      this routine.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.
```

```
       Unchanged on exit.

TRANS  - CHARACTER*1.
       On entry, TRANS specifies the equations to be solved
       as follows:

       TRANS = 'N' or 'n'   A*x = b.

       TRANS = 'T' or 't'   A'*x = b.

       TRANS = 'C' or 'c'   conjg( A' )*x = b.

       Unchanged on exit.

DIAG   - CHARACTER*1.
       On entry, DIAG specifies whether or not A is unit
       triangular as follows:

       DIAG = 'U' or 'u'   A is assumed to be unit triangu-
       lar.

       DIAG = 'N' or 'n'   A is not assumed to be unit tri-
       angular.

       Unchanged on exit.

N      - INTEGER.
       On entry, N specifies the order of the matrix A.  N
       must be at least zero.  Unchanged on exit.

K      - INTEGER.
       On entry with UPLO = 'U' or 'u', K specifies the
       number of super-diagonals of the matrix A.  On entry
       with UPLO = 'L' or 'l', K specifies the number of
       sub-diagonals of the matrix A.  K must satisfy  0
       .le. K.  Unchanged on exit.

A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
       Before entry with UPLO = 'U' or 'u', the leading ( k
       + 1 ) by n part of the array A must contain the upper
       triangular band part of the matrix of coefficients,
       supplied column by column, with the leading diagonal
       of the matrix in row ( k + 1 ) of the array, the
       first super-diagonal starting at position 2 in row k,
       and so on. The top left k by k triangle of the array
       A is not referenced.  The following program segment
       will transfer an upper triangular band matrix from
       conventional full matrix storage to band storage:

       DO 20, J = 1, N M = K + 1 - J DO 10, I = MAX( 1, J -
```

```
K ), J A( M + I, J ) = matrix( I, J ) 10    CONTINUE
20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading ( k
+ 1 ) by n part of the array A must contain the lower
triangular band part of the matrix of coefficients,
supplied column by column, with the leading diagonal
of the matrix in row 1 of the array, the first sub-
diagonal starting at position 1 in row 2, and so on.
The bottom right k by k triangle of the array A is
not referenced.  The following program segment will
transfer a lower triangular band matrix from conven-
tional full matrix storage to band storage:

DO 20, J = 1, N M = 1 - J DO 10, I = J, MIN( N, J + K
) A( M + I, J ) = matrix( I, J ) 10    CONTINUE 20
CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the
array A corresponding to the diagonal elements of the

matrix are not referenced, but are assumed to be
unity.  Unchanged on exit.

LDA    - INTEGER.
       On entry, LDA specifies the first dimension of A as
       declared in the calling (sub) program. LDA must be at
       least ( k + 1 ).  Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
       ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
       incremented array X must contain the n element
       right-hand side vector b. On exit, X is overwritten
       with the solution vector x.

INCX   - INTEGER.
       On entry, INCX specifies the increment for the ele-
       ments of X. INCX must not be zero.  Unchanged on
       exit.

      x := A*x, or x := A'*x, or x := conjg( A' )*x,

 SYNOPSIS
      SUBROUTINE ZTPMV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   AP( * ), X( * )
```

```
PURPOSE
     ZTPMV  performs one of the matrix-vector operations

     where x is an n element vector and  A is an n by n unit, or
     non-unit, upper or lower triangular matrix, supplied in
     packed form.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   x := A*x.

            TRANS = 'T' or 't'   x := A'*x.

            TRANS = 'C' or 'c'   x := conjg( A' )*x.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit

            triangular.

            Unchanged on exit.

     N      - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

     AP     - COMPLEX*16       array of DIMENSION at least
            ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
```

```
            or 'u', the array AP must contain the upper triangu-
            lar matrix packed sequentially, column by column, so
            that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
            contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
            on.  Before entry with UPLO = 'L' or 'l', the array
            AP must contain the lower triangular matrix packed
            sequentially, column by column, so that AP( 1 ) con-
            tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
            ) and a( 3, 1 ) respectively, and so on.  Note that
            when  DIAG = 'U' or 'u', the diagonal elements of A
            are not referenced, but are assumed to be unity.
            Unchanged on exit.

      X     - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x. On exit, X is overwritten with the transformed
            vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.
```

 NAME
      ZTPSV - solve one of the systems of equations
      A*x = b, or A'*x = b, or conjg( A' )*x = b,

 SYNOPSIS
      SUBROUTINE ZTPSV ( UPLO, TRANS, DIAG, N, AP, X, INCX )

          INTEGER      INCX, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   AP( * ), X( * )

 PURPOSE
      ZTPSV  solves one of the systems of equations

      where b and x are n element vectors and A is an n by n unit,
      or non-unit, upper or lower triangular matrix, supplied in
      packed form.

      No test for singularity or near-singularity is included in
      this routine. Such tests must be performed before calling
      this routine.

 PARAMETERS
      UPLO   - CHARACTER*1.
               On entry, UPLO specifies whether the matrix is an
               upper or lower triangular matrix as follows:

               UPLO = 'U' or 'u'   A is an upper triangular matrix.

               UPLO = 'L' or 'l'   A is a lower triangular matrix.

               Unchanged on exit.

      TRANS  - CHARACTER*1.
               On entry, TRANS specifies the equations to be solved
               as follows:

               TRANS = 'N' or 'n'   A*x = b.
```

```
         TRANS = 'T' or 't'   A'*x = b.

         TRANS = 'C' or 'c'   conjg( A' )*x = b.

         Unchanged on exit.

DIAG   - CHARACTER*1.
         On entry, DIAG specifies whether or not A is unit
         triangular as follows:

         DIAG = 'U' or 'u'   A is assumed to be unit triangu-
         lar.

         DIAG = 'N' or 'n'   A is not assumed to be unit tri-
         angular.

         Unchanged on exit.

N      - INTEGER.
         On entry, N specifies the order of the matrix A.  N
         must be at least zero.  Unchanged on exit.

AP     - COMPLEX*16       array of DIMENSION at least
         ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO = 'U'
         or 'u', the array AP must contain the upper triangu-
         lar matrix packed sequentially, column by column, so
         that AP( 1 ) contains a( 1, 1 ), AP( 2 ) and AP( 3 )
         contain a( 1, 2 ) and a( 2, 2 ) respectively, and so
         on.  Before entry with UPLO = 'L' or 'l', the array
         AP must contain the lower triangular matrix packed
         sequentially, column by column, so that AP( 1 ) con-
         tains a( 1, 1 ), AP( 2 ) and AP( 3 ) contain a( 2, 1
         ) and a( 3, 1 ) respectively, and so on.  Note that
         when  DIAG = 'U' or 'u', the diagonal elements of A
         are not referenced, but are assumed to be unity.
         Unchanged on exit.

X      - COMPLEX*16       array of dimension at least
         ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
         incremented array X must contain the n element
         right-hand side vector b. On exit, X is overwritten
         with the solution vector x.

INCX   - INTEGER.
         On entry, INCX specifies the increment for the ele-
         ments of X. INCX must not be zero.  Unchanged on
         exit.

 NAME
```

```
     ZTRMV - perform one of the matrix-vector operations
     x := A*x, or x := A'*x, or x := conjg( A' )*x,

SYNOPSIS
     SUBROUTINE ZTRMV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

         INTEGER      INCX, LDA, N

         CHARACTER*1  DIAG, TRANS, UPLO

         COMPLEX*16   A( LDA, * ), X( * )

PURPOSE
     ZTRMV  performs one of the matrix-vector operations

     where x is an n element vector and  A is an n by n unit, or
     non-unit, upper or lower triangular matrix.

PARAMETERS
     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry, TRANS specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   x := A*x.

            TRANS = 'T' or 't'   x := A'*x.

            TRANS = 'C' or 'c'   x := conjg( A' )*x.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.
```

```
            Unchanged on exit.

      N     - INTEGER.
            On entry, N specifies the order of the matrix A.  N
            must be at least zero.  Unchanged on exit.

      A     - COMPLEX*16       array of DIMENSION ( LDA, n ).
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular matrix and the strictly
            lower triangular part of A is not referenced.  Before
            entry with UPLO = 'L' or 'l', the leading n by n
            lower triangular part of the array A must contain the
            lower triangular matrix and the strictly upper tri-
            angular part of A is not referenced.  Note that when
            DIAG = 'U' or 'u', the diagonal elements of A are not
            referenced either, but are assumed to be unity.
            Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, n ).  Unchanged on exit.

      X     - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element vector
            x. On exit, X is overwritten with the transformed
            vector x.

      INCX  - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.

 NAME
      ZTRSV - solve one of the systems of equations
      A*x = b, or A'*x = b, or conjg( A' )*x = b,

 SYNOPSIS
      SUBROUTINE ZTRSV ( UPLO, TRANS, DIAG, N, A, LDA, X, INCX )

          INTEGER      INCX, LDA, N

          CHARACTER*1  DIAG, TRANS, UPLO

          COMPLEX*16   A( LDA, * ), X( * )

 PURPOSE
```

```
     ZTRSV  solves one of the systems of equations

     where b and x are n element vectors and A is an n by n unit,
     or non-unit, upper or lower triangular matrix.

     No test for singularity or near-singularity is included in
     this routine. Such tests must be performed before calling
     this routine.

PARAMETERS
     UPLO   - CHARACTER*1.
              On entry, UPLO specifies whether the matrix is an
              upper or lower triangular matrix as follows:

              UPLO = 'U' or 'u'   A is an upper triangular matrix.

              UPLO = 'L' or 'l'   A is a lower triangular matrix.

              Unchanged on exit.

     TRANS  - CHARACTER*1.
              On entry, TRANS specifies the equations to be solved
              as follows:

              TRANS = 'N' or 'n'   A*x = b.

              TRANS = 'T' or 't'   A'*x = b.

              TRANS = 'C' or 'c'   conjg( A' )*x = b.

              Unchanged on exit.

     DIAG   - CHARACTER*1.
              On entry, DIAG specifies whether or not A is unit
              triangular as follows:

              DIAG = 'U' or 'u'   A is assumed to be unit

              triangular.

              DIAG = 'N' or 'n'   A is not assumed to be unit tri-
              angular.

              Unchanged on exit.

     N      - INTEGER.
              On entry, N specifies the order of the matrix A.  N
              must be at least zero.  Unchanged on exit.

     A      - COMPLEX*16       array of DIMENSION ( LDA, n ).
```

```
            Before entry with  UPLO = 'U' or 'u', the leading n
            by n upper triangular part of the array A must con-
            tain the upper triangular matrix and the strictly
            lower triangular part of A is not referenced.  Before
            entry with UPLO = 'L' or 'l', the leading n by n
            lower triangular part of the array A must contain the
            lower triangular matrix and the strictly upper tri-
            angular part of A is not referenced.  Note that when
            DIAG = 'U' or 'u', the diagonal elements of A are not
            referenced either, but are assumed to be unity.
            Unchanged on exit.

      LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program. LDA must be at
            least max( 1, n ).  Unchanged on exit.

      X      - COMPLEX*16       array of dimension at least
            ( 1 + ( n - 1 )*abs( INCX ) ).  Before entry, the
            incremented array X must contain the n element
            right-hand side vector b. On exit, X is overwritten
            with the solution vector x.

      INCX   - INTEGER.
            On entry, INCX specifies the increment for the ele-
            ments of X. INCX must not be zero.  Unchanged on
            exit.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgemm (TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA,
           C, LDC)
           SGEMM

Function/Subroutine Documentation
   subroutine sgemm (character TRANSA, character TRANSB, integer M, integer N,
       integer K, real ALPHA, real, dimension(lda,*) A, integer LDA, real,
       dimension(ldb,*) B, integer LDB, real BETA, real, dimension(ldc,*) C,
       integer LDC)
       SGEMM

Purpose:
   SGEMM  performs one of the matrix-matrix operations

   C := alpha*op( A )*op( B ) + beta*C,

   where  op( X ) is one of

   op( X ) = X   or   op( X ) = X**T,

   alpha and beta are scalars, and A, B and C are matrices, with op( A )
   an m by k matrix,  op( B )  a  k by n matrix and  C an m by n matrix.

Parameters:

 TRANSA
   TRANSA is CHARACTER*1
   On entry, TRANSA specifies the form of op( A ) to be used in
   the matrix multiplication as follows:

   TRANSA = 'N' or 'n',  op( A ) = A.

   TRANSA = 'T' or 't',  op( A ) = A**T.

   TRANSA = 'C' or 'c',  op( A ) = A**T.

 TRANSB
   TRANSB is CHARACTER*1
   On entry, TRANSB specifies the form of op( B ) to be used in
   the matrix multiplication as follows:

   TRANSB = 'N' or 'n',  op( B ) = B.
```

```
  TRANSB = 'T' or 't',  op( B ) = B**T.

  TRANSB = 'C' or 'c',  op( B ) = B**T.

M
  M is INTEGER
  On entry,  M  specifies  the number  of rows  of the  matrix
  op( A )  and of the  matrix  C.  M  must  be at least  zero.

N
  N is INTEGER
  On entry,  N  specifies the number  of columns of the matrix
  op( B ) and the number of columns of the matrix C. N must be
  at least zero.

K
  K is INTEGER
  On entry,  K  specifies  the number of columns of the matrix
  op( A ) and the number of rows of the matrix op( B ). K must
  be at least  zero.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.

A
  A is REAL array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANSA = 'N' or 'n',  and is  m  otherwise.
  Before entry with  TRANSA = 'N' or 'n',  the leading  m by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by m  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. When  TRANSA = 'N' or 'n' then
  LDA must be at least  max( 1, m ), otherwise  LDA must be at
  least  max( 1, k ).

B
  B is REAL array of DIMENSION ( LDB, kb ), where kb is
  n  when  TRANSB = 'N' or 'n',  and is  k  otherwise.
  Before entry with  TRANSB = 'N' or 'n',  the leading  k by n
  part of the array  B  must contain the matrix  B,  otherwise
  the leading  n by k  part of the array  B  must contain  the
  matrix B.

LDB
  LDB is INTEGER
```

```
  On entry, LDB specifies the first dimension of B as declared
  in the calling (sub) program. When  TRANSB = 'N' or 'n' then
  LDB must be at least  max( 1, k ), otherwise  LDB must be at
  least  max( 1, n ).

BETA
  BETA is REAL
  On entry,  BETA  specifies the scalar  beta.  When  BETA  is
  supplied as zero then C need not be set on input.

C
  C is REAL array of DIMENSION ( LDC, n ).
  Before entry, the leading  m by n  part of the array  C must
  contain the matrix  C,  except when  beta  is zero, in which
  case C need not be set on entry.
  On exit, the array  C  is overwritten by the  m by n  matrix
  ( alpha*op( A )*op( B ) + beta*C ).

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least max( 1, m ).

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine ssymm (SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
           LDC)
           SSYMM

Function/Subroutine Documentation
   subroutine ssymm (character SIDE, character UPLO, integer M, integer N,
       real ALPHA, real, dimension(lda,*) A, integer LDA, real,
       dimension(ldb,*) B, integer LDB, real BETA, real, dimension(ldc,*) C,
       integer LDC)
       SSYMM

Purpose:
   SSYMM  performs one of the matrix-matrix operations

     C := alpha*A*B + beta*C,

   or

     C := alpha*B*A + beta*C,

   where alpha and beta are scalars,  A is a symmetric matrix and  B and
   C are  m by n matrices.
```

```
Parameters:

 SIDE
   SIDE is CHARACTER*1
   On entry,  SIDE  specifies whether  the  symmetric matrix  A
   appears on the  left or right  in the  operation as follows:

   SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

   SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

 UPLO
   UPLO is CHARACTER*1
   On  entry,  UPLO  specifies  whether  the  upper  or  lower
   triangular  part  of  the  symmetric  matrix  A  is  to  be
   referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of the
   symmetric matrix is to be referenced.

   UPLO = 'L' or 'l'   Only the lower triangular part of the
   symmetric matrix is to be referenced.

 M
   M is INTEGER
   On entry,  M  specifies the number of rows of the matrix  C.
   M  must be at least zero.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix C.
   N  must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 A
   A is REAL array of DIMENSION ( LDA, ka ), where ka is
   m  when  SIDE = 'L' or 'l'  and is  n otherwise.

   Before entry  with  SIDE = 'L' or 'l',  the  m by m  part of
   the array  A  must contain the  symmetric matrix,  such that
   when  UPLO = 'U' or 'u', the leading m by m upper triangular
   part of the array  A  must contain the upper triangular part
   of the  symmetric matrix and the  strictly  lower triangular
   part of  A  is not referenced,  and when  UPLO = 'L' or 'l',
   the leading  m by m  lower triangular part  of the  array  A
   must  contain  the  lower triangular part  of the  symmetric
```

```
  matrix and the  strictly upper triangular part of  A  is not
  referenced.

  Before entry  with  SIDE = 'R' or 'r',  the  n by n  part of
  the array  A  must contain the  symmetric matrix,  such that
  when  UPLO = 'U' or 'u', the leading n by n upper triangular
  part of the array  A  must contain the upper triangular part
  of the  symmetric matrix and the  strictly  lower triangular
  part of  A  is not referenced,  and when  UPLO = 'L' or 'l',
  the leading  n by n  lower triangular part  of the  array  A
  must  contain  the  lower triangular part  of the  symmetric
  matrix and the  strictly upper triangular part of  A  is not
  referenced.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program.  When  SIDE = 'L' or 'l'  then
  LDA must be at least  max( 1, m ), otherwise  LDA must be at
  least  max( 1, n ).

B
  B is REAL array of DIMENSION ( LDB, n ).
  Before entry, the leading  m by n part of the array  B  must
  contain the matrix B.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.  LDB  must  be  at  least
  max( 1, m ).

BETA
  BETA is REAL
  On entry,  BETA  specifies the scalar  beta.  When  BETA  is
  supplied as zero then C need not be set on input.

C
  C is REAL array of DIMENSION ( LDC, n ).
  Before entry, the leading  m by n  part of the array  C must
  contain the matrix  C,  except when  beta  is zero, in which
  case C need not be set on entry.
  On exit, the array  C  is overwritten by the  m by n updated
  matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, m ).

SYNOPSIS
   Functions/Subroutines
       subroutine ssyr2k (UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
           LDC)
           SSYR2K

Function/Subroutine Documentation
   subroutine ssyr2k (character UPLO, character TRANS, integer N, integer K,
       real ALPHA, real, dimension(lda,*) A, integer LDA, real,
       dimension(ldb,*) B, integer LDB, real BETA, real, dimension(ldc,*) C,
       integer LDC)
       SSYR2K

Purpose:
   SSYR2K  performs one of the symmetric rank 2k operations

     C := alpha*A*B**T + alpha*B*A**T + beta*C,

   or

     C := alpha*A**T*B + alpha*B**T*A + beta*C,

   where  alpha and beta  are scalars, C is an  n by n  symmetric matrix
   and  A and B  are  n by k  matrices  in the  first  case  and  k by n
   matrices in the second case.

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  On  entry,   UPLO  specifies  whether  the  upper  or  lower
  triangular  part  of the  array  C  is to be  referenced  as follows:

  UPLO = 'U' or 'u'   Only the  upper triangular part of  C
  is to be referenced.

  UPLO = 'L' or 'l'   Only the  lower triangular part of  C
  is to be referenced.

TRANS
  TRANS is CHARACTER*1
  On entry,  TRANS  specifies the operation to be performed as follows:

  TRANS = 'N' or 'n'   C := alpha*A*B**T + alpha*B*A**T + beta*C.

  TRANS = 'T' or 't'   C := alpha*A**T*B + alpha*B**T*A + beta*C.

  TRANS = 'C' or 'c'   C := alpha*A**T*B + alpha*B**T*A + beta*C.

N
  N is INTEGER
  On entry,  N specifies the order of the matrix C.  N must be
  at least zero.

K
  K is INTEGER
  On entry with  TRANS = 'N' or 'n',  K  specifies  the number
  of  columns  of the  matrices  A and B,  and on  entry  with
  TRANS = 'T' or 't' or 'C' or 'c',  K  specifies  the  number
  of rows of the matrices  A and B.  K must be at least  zero.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.

A
  A is REAL array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by n  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in  the  calling  (sub)  program.   When  TRANS = 'N' or 'n'
```

```
  then  LDA must be at least  max( 1, n ), otherwise  LDA must
  be at least  max( 1, k ).

B
  B is REAL array of DIMENSION ( LDB, kb ), where kb is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  B  must contain the matrix  B,  otherwise
  the leading  k by n  part of the array  B  must contain  the
  matrix B.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.   When  TRANS = 'N' or 'n'
  then  LDB must be at least  max( 1, n ), otherwise  LDB must
  be at least  max( 1, k ).

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta.

C
  C is REAL array of DIMENSION ( LDC, n ).

  Before entry  with  UPLO = 'U' or 'u',  the leading  n by n
  upper triangular part of the array C must contain the upper
  triangular part  of the  symmetric matrix  and the strictly
  lower triangular part of C is not referenced.  On exit, the
  upper triangular part of the array  C is overwritten by the
  upper triangular part of the updated matrix.

  Before entry  with  UPLO = 'L' or 'l',  the leading  n by n
  lower triangular part of the array C must contain the lower
  triangular part  of the  symmetric matrix  and the strictly
  upper triangular part of C is not referenced.  On exit, the
  lower triangular part of the array  C is overwritten by the
  lower triangular part of the updated matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, n ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyrk (UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
           SSYRK

Function/Subroutine Documentation
   subroutine ssyrk (character UPLO, character TRANS, integer N, integer K,
       real ALPHA, real, dimension(lda,*) A, integer LDA, real BETA, real,
       dimension(ldc,*) C, integer LDC)
       SSYRK

Purpose:
   SSYRK  performs one of the symmetric rank k operations

     C := alpha*A*A**T + beta*C,

   or

     C := alpha*A**T*A + beta*C,

   where  alpha and beta  are scalars, C is an  n by n  symmetric matrix
   and  A  is an  n by k  matrix in the first case and a  k by n  matrix
```

```
   in the second case.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On  entry,  UPLO  specifies  whether  the  upper  or  lower
   triangular  part  of the  array  C  is to be  referenced  as
   follows:

   UPLO = 'U' or 'u'   Only the  upper triangular part of  C
   is to be referenced.

   UPLO = 'L' or 'l'   Only the  lower triangular part of  C
   is to be referenced.

 TRANS
   TRANS is CHARACTER*1
   On entry,  TRANS  specifies the operation to be performed as
   follows:

   TRANS = 'N' or 'n'   C := alpha*A*A**T + beta*C.

   TRANS = 'T' or 't'   C := alpha*A**T*A + beta*C.

   TRANS = 'C' or 'c'   C := alpha*A**T*A + beta*C.

 N
   N is INTEGER
   On entry,  N specifies the order of the matrix C.  N must be
   at least zero.

 K
   K is INTEGER
   On entry with  TRANS = 'N' or 'n',  K  specifies  the number
   of  columns  of  the  matrix  A,  and  on  entry  with
   TRANS = 'T' or 't' or 'C' or 'c',  K  specifies  the  number
   of rows of the matrix  A.  K must be at least zero.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.

 A
   A is REAL array of DIMENSION ( LDA, ka ), where ka is
   k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
   Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
   part of the array  A  must contain the matrix  A,  otherwise
   the leading  k by n  part of the array  A  must contain  the
   matrix A.
```

```
LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in  the  calling  (sub)  program.   When  TRANS = 'N' or 'n'
  then  LDA must be at least  max( 1, n ), otherwise  LDA must
  be at least  max( 1, k ).

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta.

C
  C is REAL array of DIMENSION ( LDC, n ).

  Before entry  with  UPLO = 'U' or 'u',  the leading  n by n
  upper triangular part of the array C must contain the upper
  triangular part  of the  symmetric matrix  and the strictly
  lower triangular part of C is not referenced.  On exit, the
  upper triangular part of the array  C is overwritten by the
  upper triangular part of the updated matrix.

  Before entry  with  UPLO = 'L' or 'l',  the leading  n by n
  lower triangular part of the array C must contain the lower
  triangular part  of the  symmetric matrix  and the strictly
  upper triangular part of C is not referenced.  On exit, the
  lower triangular part of the array  C is overwritten by the
  lower triangular part of the updated matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.   LDC  must  be  at  least
  max( 1, n ).

SYNOPSIS
   Functions/Subroutines
       subroutine strmm (SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
           LDB)
           STRMM

Function/Subroutine Documentation
   subroutine strmm (character SIDE, character UPLO, character TRANSA,
       character DIAG, integer M, integer N, real ALPHA, real,
       dimension(lda,*) A, integer LDA, real, dimension(ldb,*) B, integer LDB)
       STRMM

Purpose:
   STRMM  performs one of the matrix-matrix operations

     B := alpha*op( A )*B,   or   B := alpha*B*op( A ),

   where  alpha  is a scalar,  B  is an m by n matrix,  A  is a unit, or
   non-unit,  upper or lower triangular matrix  and  op( A )  is one  of

     op( A ) = A   or   op( A ) = A**T.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   On entry,  SIDE specifies whether  op( A ) multiplies B from
   the left or right as follows:

   SIDE = 'L' or 'l'   B := alpha*op( A )*B.

   SIDE = 'R' or 'r'   B := alpha*B*op( A ).

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix A is an upper or
   lower triangular matrix as follows:
```

```
  UPLO = 'U' or 'u'   A is an upper triangular matrix.

  UPLO = 'L' or 'l'   A is a lower triangular matrix.

TRANSA
  TRANSA is CHARACTER*1
  On entry, TRANSA specifies the form of op( A ) to be used in
  the matrix multiplication as follows:

  TRANSA = 'N' or 'n'   op( A ) = A.

  TRANSA = 'T' or 't'   op( A ) = A**T.

  TRANSA = 'C' or 'c'   op( A ) = A**T.

DIAG
  DIAG is CHARACTER*1
  On entry, DIAG specifies whether or not A is unit triangular
  as follows:

  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

M
  M is INTEGER
  On entry, M specifies the number of rows of B. M must be at
  least zero.

N
  N is INTEGER
  On entry, N specifies the number of columns of B.  N must be
  at least zero.

ALPHA
  ALPHA is REAL
  On entry,  ALPHA specifies the scalar  alpha. When  alpha is
  zero then  A is not referenced and  B need not be set before entry.

A
  A is REAL array of DIMENSION ( LDA, k ), where k is m
  when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R' or 'r'.
  Before entry  with  UPLO = 'U' or 'u',  the  leading  k by k
  upper triangular part of the array  A must contain the upper
  triangular matrix  and the strictly lower triangular part of
  A is not referenced.

  Before entry  with  UPLO = 'L' or 'l',  the  leading  k by k
  lower triangular part of the array  A must contain the lower
```

```
  triangular matrix  and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u',  the diagonal elements of
  A  are not referenced either,  but are assumed to be  unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program.  When  SIDE = 'L' or 'l'  then
  LDA  must be at least  max( 1, m ),  when  SIDE = 'R' or 'r'
  then LDA must be at least max( 1, n ).

B
  B is REAL array of DIMENSION ( LDB, n ).
  Before entry,  the leading  m by n part of the array  B must
  contain the matrix  B,  and  on exit  is overwritten  by the
  transformed matrix.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.  LDB  must  be  at  least
  max( 1, m ).

SYNOPSIS
   Functions/Subroutines
       subroutine strsm (SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
           LDB)
           STRSM

Function/Subroutine Documentation
   subroutine strsm (character SIDE, character UPLO, character TRANSA,
       character DIAG, integer M, integer N, real ALPHA, real,
       dimension(lda,*) A, integer LDA, real, dimension(ldb,*) B, integer LDB)
       STRSM

Purpose:
   STRSM  solves one of the matrix equations

     op( A )*X = alpha*B,   or   X*op( A ) = alpha*B,

   where alpha is a scalar, X and B are m by n matrices, A is a unit, or
   non-unit,  upper or lower triangular matrix  and  op( A )  is one  of

     op( A ) = A   or   op( A ) = A**T.

   The matrix X is overwritten on B.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   On entry, SIDE specifies whether op( A ) appears on the left
   or right of X as follows:

   SIDE = 'L' or 'l'   op( A )*X = alpha*B.

   SIDE = 'R' or 'r'   X*op( A ) = alpha*B.

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix A is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANSA
   TRANSA is CHARACTER*1
   On entry, TRANSA specifies the form of op( A ) to be used in
   the matrix multiplication as follows:
```

```
  TRANSA = 'N' or 'n'   op( A ) = A.

  TRANSA = 'T' or 't'   op( A ) = A**T.

  TRANSA = 'C' or 'c'   op( A ) = A**T.

DIAG
  DIAG is CHARACTER*1
  On entry, DIAG specifies whether or not A is unit triangular
  as follows:

  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

M
  M is INTEGER
  On entry, M specifies the number of rows of B. M must be at
  least zero.

N
  N is INTEGER
  On entry, N specifies the number of columns of B.  N must be
  at least zero.

ALPHA
  ALPHA is REAL
  On entry,  ALPHA specifies the scalar  alpha. When  alpha is
  zero then  A is not referenced and  B need not be set before entry.

A
  A is REAL array of DIMENSION ( LDA, k ),
  where k is m when SIDE = 'L' or 'l'
  and k is n when SIDE = 'R' or 'r'.

  Before entry  with  UPLO = 'U' or 'u',  the  leading  k by k
  upper triangular part of the array  A must contain the upper
  triangular matrix  and the strictly lower triangular part of
  A is not referenced.

  Before entry  with  UPLO = 'L' or 'l',  the  leading  k by k
  lower triangular part of the array  A must contain the lower
  triangular matrix  and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u',  the diagonal elements of
  A  are not referenced either,  but are assumed to be  unity.

LDA
```

```
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program.  When  SIDE = 'L' or 'l'  then
  LDA  must be at least  max( 1, m ),  when  SIDE = 'R' or 'r'
  then LDA must be at least max( 1, n ).

B
  B is REAL array of DIMENSION ( LDB, n ).
  Before entry,  the leading  m by n part of the array  B must
  contain  the  right-hand  side  matrix  B,  and  on exit  is
  overwritten by the solution matrix  X.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.  LDB  must  be  at  least
  max( 1, m ).

 NAME
      DGEMM - perform one of the matrix-matrix operations   C :=
      alpha*op( A )*op( B ) + beta*C,

 SYNOPSIS
      SUBROUTINE DGEMM ( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA,
                       B, LDB, BETA, C, LDC )

          CHARACTER*1  TRANSA, TRANSB

          INTEGER      M, N, K, LDA, LDB, LDC

          DOUBLE       PRECISION ALPHA, BETA

          DOUBLE       PRECISION A( LDA, * ), B( LDB, * ), C( LDC,
                       * )

 PURPOSE
      DGEMM  performs one of the matrix-matrix operations

      where  op( X ) is one of

         op( X ) = X   or   op( X ) = X',

      alpha and beta are scalars, and A, B and C are matrices,
      with op( A ) an m by k matrix,  op( B )  a  k by n matrix
      and  C an m by n matrix.

 PARAMETERS
      TRANSA - CHARACTER*1.  On entry, TRANSA specifies the form
      of op( A ) to be used in the matrix multiplication as fol-
      lows:

      TRANSA = 'N' or 'n',  op( A ) = A.

      TRANSA = 'T' or 't',  op( A ) = A'.

      TRANSA = 'C' or 'c',  op( A ) = A'.

      Unchanged on exit.

      TRANSB - CHARACTER*1.  On entry, TRANSB specifies the form
      of op( B ) to be used in the matrix multiplication as fol-
      lows:
```

```
     TRANSB = 'N' or 'n',  op( B ) = B.

     TRANSB = 'T' or 't',  op( B ) = B'.

     TRANSB = 'C' or 'c',  op( B ) = B'.

     Unchanged on exit.

     M      - INTEGER.
              On entry,  M  specifies  the number  of rows  of the
              matrix op( A )  and of the  matrix  C.  M  must  be
              at least  zero.  Unchanged on exit.

     N      - INTEGER.
              On entry,  N  specifies the number  of columns of the
              matrix op( B ) and the number of columns of the
              matrix C. N must be at least zero.  Unchanged on
              exit.

     K      - INTEGER.
              On entry,  K  specifies  the number of columns of the
              matrix op( A ) and the number of rows of the matrix
              op( B ). K must be at least  zero.  Unchanged on
              exit.

     ALPHA  - DOUBLE PRECISION.
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

ka is
     A      -
               DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
              k  when  TRANSA = 'N' or 'n',  and is  m  otherwise.
              Before entry with  TRANSA = 'N' or 'n',  the leading
              m by k part of the array  A  must contain the matrix
              A,  otherwise the leading  k by m  part of the array
              A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
              On entry, LDA specifies the first dimension of A as
              declared in the calling (sub) program. When  TRANSA =
              'N' or 'n' then LDA must be at least  max( 1, m ),
              otherwise  LDA must be at least  max( 1, k ).
              Unchanged on exit.

kb is
     B      -
               DOUBLE PRECISION array of DIMENSION ( LDB, kb ), where
              n  when  TRANSB = 'N' or 'n',  and is  k  otherwise.
              Before entry with  TRANSB = 'N' or 'n',  the leading
```

```
            k by n part of the array  B  must contain the matrix
            B,  otherwise the leading  n by k  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

      LDB    - INTEGER.
             On entry, LDB specifies the first dimension of B as
             declared in the calling (sub) program. When  TRANSB =
             'N' or 'n' then LDB must be at least  max( 1, k ),

             otherwise  LDB must be at least  max( 1, n ).
             Unchanged on exit.

      BETA   - DOUBLE PRECISION.
             On entry,  BETA  specifies the scalar  beta.  When
             BETA  is supplied as zero then C need not be set on
             input.  Unchanged on exit.

      C      - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
             Before entry, the leading  m by n  part of the array
             C must contain the matrix  C,  except when  beta  is
             zero, in which case C need not be set on entry.  On
             exit, the array  C  is overwritten by the  m by n
             matrix ( alpha*op( A )*op( B ) + beta*C ).

      LDC    - INTEGER.
             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      DSYMM - perform one of the matrix-matrix operations   C :=
      alpha*A*B + beta*C,

 SYNOPSIS
      SUBROUTINE DSYMM ( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1  SIDE, UPLO

          INTEGER      M, N, LDA, LDB, LDC

          DOUBLE       PRECISION ALPHA, BETA

          DOUBLE       PRECISION A( LDA, * ), B( LDB, * ), C( LDC,
                       * )

 PURPOSE
      DSYMM  performs one of the matrix-matrix operations

      or

         C := alpha*B*A + beta*C,
```

```
     where alpha and beta are scalars,  A is a symmetric matrix
     and  B and C are  m by n matrices.

PARAMETERS
     SIDE   - CHARACTER*1.
            On entry,  SIDE  specifies whether  the  symmetric
            matrix  A appears on the  left or right  in the
            operation as follows:

            SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

            SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On  entry,   UPLO  specifies  whether  the  upper  or
            lower triangular  part  of  the  symmetric  matrix
            A  is  to  be referenced as follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            the symmetric matrix is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            the symmetric matrix is to be referenced.

            Unchanged on exit.

     M      - INTEGER.
            On entry,  M  specifies the number of rows of the
            matrix  C.  M  must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix C.  N  must be at least zero.  Unchanged on
            exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
     A      -
             DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
            m  when  SIDE = 'L' or 'l'  and is  n otherwise.
            Before entry  with  SIDE = 'L' or 'l',  the  m by m
            part of the array  A  must contain the  symmetric
            matrix,  such that when  UPLO = 'U' or 'u', the lead-
            ing m by m upper triangular part of the array  A
```

```
        must contain the upper triangular part of the  sym-
        metric matrix and the  strictly  lower triangular
        part of  A  is not referenced,  and when  UPLO = 'L'
        or 'l', the leading  m by m  lower triangular part
        of the  array  A must  contain  the  lower triangular
        part  of the  symmetric matrix and the  strictly
        upper triangular part of  A  is not referenced.
        Before entry  with  SIDE = 'R' or 'r',  the  n by n
        part of the array  A  must contain the  symmetric
        matrix,  such that when  UPLO = 'U' or 'u', the lead-
        ing n by n upper triangular part of the array  A
        must contain the upper triangular part of the  sym-
        metric matrix and the  strictly  lower triangular
        part of  A  is not referenced,  and when  UPLO = 'L'
        or 'l', the leading  n by n  lower triangular part
        of the  array  A must  contain  the  lower triangular
        part  of the  symmetric matrix and the  strictly
        upper triangular part of  A  is not referenced.
        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the calling (sub) program.  When  SIDE =
        'L' or 'l'  then LDA must be at least  max( 1, m ),
        otherwise  LDA must be at least  max( 1, n ).
        Unchanged on exit.

B       - DOUBLE PRECISION array of DIMENSION ( LDB, n ).
        Before entry, the leading  m by n part of the array
        B  must contain the matrix B.  Unchanged on exit.

LDB     - INTEGER.
        On entry, LDB specifies the first dimension of B as
        declared in  the  calling  (sub)  program.   LDB
        must  be  at  least max( 1, m ).  Unchanged on exit.

BETA    - DOUBLE PRECISION.
        On entry,  BETA  specifies the scalar  beta.  When
        BETA  is supplied as zero then C need not be set on
        input.  Unchanged on exit.

C       - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
        Before entry, the leading  m by n  part of the array
        C must contain the matrix  C,  except when  beta  is
        zero, in which case C need not be set on entry.  On
        exit, the array  C  is overwritten by the  m by n
        updated matrix.

LDC     - INTEGER.
        On entry, LDC specifies the first dimension of C as
```

```
declared in  the  calling  (sub)  program.   LDC
must  be  at  least max( 1, m ).  Unchanged on exit.

Level 3 Blas routine.

 NAME
      DSYR2K - perform one of the symmetric rank 2k operations   C
      := alpha*A*B' + alpha*B*A' + beta*C,

 SYNOPSIS
      SUBROUTINE DSYR2K( UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB,
```

```
                    BETA, C, LDC )

      CHARACTER*1   UPLO, TRANS

      INTEGER       N, K, LDA, LDB, LDC

      DOUBLE        PRECISION ALPHA, BETA

      DOUBLE        PRECISION A( LDA, * ), B( LDB, * ), C(
                    LDC, * )

PURPOSE
     DSYR2K  performs one of the symmetric rank 2k operations

     or

        C := alpha*A'*B + alpha*B'*A + beta*C,

     where  alpha and beta  are scalars, C is an  n by n  sym-
     metric matrix and  A and B  are  n by k  matrices  in the
     first  case  and  k by n matrices in the second case.

PARAMETERS
     UPLO   - CHARACTER*1.
            On  entry,  UPLO  specifies  whether  the  upper  or
            lower triangular  part  of the  array  C  is to be
            referenced  as follows:

            UPLO = 'U' or 'u'   Only the  upper triangular part
            of  C is to be referenced.

            UPLO = 'L' or 'l'   Only the  lower triangular part
            of  C is to be referenced.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   C := alpha*A*B' + alpha*B*A' +
            beta*C.

            TRANS = 'T' or 't'   C := alpha*A'*B + alpha*B'*A +
            beta*C.

            TRANS = 'C' or 'c'   C := alpha*A'*B + alpha*B'*A +
            beta*C.

            Unchanged on exit.
```

```
     N      - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.

     K      - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns  of the  matrices  A and B,  and
            on  entry  with TRANS = 'T' or 't' or 'C' or 'c',  K
            specifies  the  number of rows of the matrices  A and
            B.  K must be at least  zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
     A      -
             DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

kb is
     B      -
             DOUBLE PRECISION array of DIMENSION ( LDB, kb ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  B  must contain the matrix
            B,  otherwise the leading  k by n  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDB must be at least  max(
            1, n ), otherwise  LDB must be at least  max( 1, k ).
            Unchanged on exit.

     BETA   - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta.  Unchanged
```

```
            on exit.

      C     - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  symmetric
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  symmetric matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.

      LDC   - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      DSYRK - perform one of the symmetric rank k operations   C
      := alpha*A*A' + beta*C,

 SYNOPSIS
      SUBROUTINE DSYRK ( UPLO, TRANS, N, K, ALPHA, A, LDA, BETA,
                         C, LDC )

          CHARACTER*1  UPLO, TRANS

          INTEGER      N, K, LDA, LDC

          DOUBLE       PRECISION ALPHA, BETA

          DOUBLE       PRECISION A( LDA, * ), C( LDC, * )

 PURPOSE
      DSYRK  performs one of the symmetric rank k operations

      or

         C := alpha*A'*A + beta*C,

      where  alpha and beta  are scalars, C is an  n by n  sym-
      metric matrix and  A  is an  n by k  matrix in the first
      case and a  k by n  matrix in the second case.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On  entry,  UPLO  specifies  whether  the  upper  or
             lower triangular  part  of the  array  C  is to be
             referenced  as follows:

             UPLO = 'U' or 'u'   Only the  upper triangular part
             of  C is to be referenced.

             UPLO = 'L' or 'l'   Only the  lower triangular part
             of  C is to be referenced.

             Unchanged on exit.

      TRANS  - CHARACTER*1.
```

```
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   C := alpha*A*A' + beta*C.

            TRANS = 'T' or 't'   C := alpha*A'*A + beta*C.

            TRANS = 'C' or 'c'   C := alpha*A'*A + beta*C.

            Unchanged on exit.

     N      - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.

     K      - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns   of  the   matrix   A,   and  on
            entry   with TRANS = 'T' or 't' or 'C' or 'c',  K
            specifies  the  number of rows of the matrix  A.  K
            must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
     A      -
             DOUBLE PRECISION array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

     BETA   - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

     C      - DOUBLE PRECISION array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  symmetric
```

```
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  symmetric matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.

      LDC    - INTEGER.
             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, n ).  Unchanged on exit.

 NAME
      DTRMM - perform one of the matrix-matrix operations   B :=
      alpha*op( A )*B, or B := alpha*B*op( A ),

 SYNOPSIS
      SUBROUTINE DTRMM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                         LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB

          DOUBLE       PRECISION ALPHA
```

```
         DOUBLE       PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
     DTRMM  performs one of the matrix-matrix operations

     where  alpha  is a scalar,  B  is an m by n matrix,  A  is a
     unit, or non-unit,  upper or lower triangular matrix  and
     op( A )  is one  of

        op( A ) = A   or   op( A ) = A'.

PARAMETERS
     SIDE   - CHARACTER*1.
            On entry,  SIDE specifies whether  op( A ) multiplies
            B from the left or right as follows:

            SIDE = 'L' or 'l'   B := alpha*op( A )*B.

            SIDE = 'R' or 'r'   B := alpha*B*op( A ).

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix A is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

            TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
            form of op( A ) to be used in the matrix multiplica-
            tion as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = A'.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.
```

```
            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

      M     - INTEGER.
            On entry, M specifies the number of rows of B. M must
            be at least zero.  Unchanged on exit.

      N     - INTEGER.
            On entry, N specifies the number of columns of B.  N
            must be at least zero.  Unchanged on exit.

      ALPHA - DOUBLE PRECISION.
            On entry,  ALPHA specifies the scalar  alpha. When
            alpha is zero then  A is not referenced and  B need
            not be set before entry.  Unchanged on exit.

 is m
      A     -
             DOUBLE PRECISION array of DIMENSION ( LDA, k ), where k
            when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
            or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
            leading  k by k upper triangular part of the array  A
            must contain the upper triangular matrix  and the
            strictly lower triangular part of A is not refer-
            enced.  Before entry  with  UPLO = 'L' or 'l',  the
            leading  k by k lower triangular part of the array  A
            must contain the lower triangular matrix  and the
            strictly upper triangular part of A is not refer-
            enced.  Note that when  DIAG = 'U' or 'u',  the diag-
            onal elements of A  are not referenced either,  but
            are assumed to be  unity.  Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program.  When  SIDE =
            'L' or 'l'  then LDA  must be at least  max( 1, m ),
            when  SIDE = 'R' or 'r' then LDA must be at least

            max( 1, n ).  Unchanged on exit.

      B     - DOUBLE PRECISION array of DIMENSION ( LDB, n ).
            Before entry,  the leading  m by n part of the array
            B must contain the matrix  B,  and  on exit  is
            overwritten  by the transformed matrix.

      LDB   - INTEGER.
            On entry, LDB specifies the first dimension of B as
```

```
declared in  the  calling  (sub)  program.   LDB
must  be  at  least max( 1, m ).  Unchanged on exit.
```

 NAME
      DTRSM - solve one of the matrix equations   op( A )*X =
      alpha*B, or X*op( A ) = alpha*B,

 SYNOPSIS
      SUBROUTINE DTRSM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                         LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB
```

```
          DOUBLE       PRECISION ALPHA

          DOUBLE       PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
     DTRSM  solves one of the matrix equations

     where alpha is a scalar, X and B are m by n matrices, A is a
     unit, or non-unit,  upper or lower triangular matrix  and
     op( A )  is one  of

        op( A ) = A   or   op( A ) = A'.

     The matrix X is overwritten on B.

PARAMETERS
     SIDE   - CHARACTER*1.
            On entry, SIDE specifies whether op( A ) appears on
            the left or right of X as follows:

            SIDE = 'L' or 'l'   op( A )*X = alpha*B.

            SIDE = 'R' or 'r'   X*op( A ) = alpha*B.

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix A is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

            TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
            form of op( A ) to be used in the matrix multiplica-
            tion as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = A'.

            Unchanged on exit.

     DIAG   - CHARACTER*1.
```

```
          On entry, DIAG specifies whether or not A is unit
          triangular as follows:

          DIAG = 'U' or 'u'   A is assumed to be unit triangu-
          lar.

          DIAG = 'N' or 'n'   A is not assumed to be unit tri-
          angular.

          Unchanged on exit.

     M      - INTEGER.
          On entry, M specifies the number of rows of B. M must
          be at least zero.  Unchanged on exit.

     N      - INTEGER.
          On entry, N specifies the number of columns of B.  N
          must be at least zero.  Unchanged on exit.

     ALPHA  - DOUBLE PRECISION.
          On entry,  ALPHA specifies the scalar  alpha. When
          alpha is zero then  A is not referenced and  B need
          not be set before entry.  Unchanged on exit.

is m
     A      -
           DOUBLE PRECISION array of DIMENSION ( LDA, k ), where k
          when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
          or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
          leading  k by k upper triangular part of the array  A
          must contain the upper triangular matrix  and the
          strictly lower triangular part of A is not refer-
          enced.  Before entry  with  UPLO = 'L' or 'l',  the
          leading  k by k lower triangular part of the array  A
          must contain the lower triangular matrix  and the
          strictly upper triangular part of A is not refer-
          enced.  Note that when  DIAG = 'U' or 'u',  the diag-
          onal elements of A  are not referenced either,  but
          are assumed to be  unity.  Unchanged on exit.

     LDA    - INTEGER.
          On entry, LDA specifies the first dimension of A as
          declared in the calling (sub) program.  When  SIDE =

          'L' or 'l'  then LDA  must be at least  max( 1, m ),
          when  SIDE = 'R' or 'r' then LDA must be at least
          max( 1, n ).  Unchanged on exit.

     B      - DOUBLE PRECISION array of DIMENSION ( LDB, n ).
          Before entry,  the leading  m by n part of the array
```

```
            B must contain  the  right-hand  side  matrix  B,
            and  on exit  is overwritten by the solution matrix
            X.

      LDB    - INTEGER.
             On entry, LDB specifies the first dimension of B as
             declared in  the  calling  (sub)  program.   LDB
             must  be  at  least max( 1, m ).  Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgemm (TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB, BETA,
           C, LDC)
           CGEMM

Function/Subroutine Documentation
   subroutine cgemm (character TRANSA, character TRANSB, integer M, integer N,
       integer K, complex ALPHA, complex, dimension(lda,*) A, integer LDA,
       complex, dimension(ldb,*) B, integer LDB, complex BETA, complex,
       dimension(ldc,*) C, integer LDC)
       CGEMM

Purpose:
   CGEMM  performs one of the matrix-matrix operations

   C := alpha*op( A )*op( B ) + beta*C,

   where  op( X ) is one of

   op( X ) = X   or   op( X ) = X**T   or   op( X ) = X**H,

   alpha and beta are scalars, and A, B and C are matrices, with op( A )
   an m by k matrix,  op( B )  a  k by n matrix and  C an m by n matrix.

Parameters:

 TRANSA
   TRANSA is CHARACTER*1
   On entry, TRANSA specifies the form of op( A ) to be used in
   the matrix multiplication as follows:

   TRANSA = 'N' or 'n',  op( A ) = A.

   TRANSA = 'T' or 't',  op( A ) = A**T.

   TRANSA = 'C' or 'c',  op( A ) = A**H.

 TRANSB
   TRANSB is CHARACTER*1
   On entry, TRANSB specifies the form of op( B ) to be used in
   the matrix multiplication as follows:

   TRANSB = 'N' or 'n',  op( B ) = B.
```

```
  TRANSB = 'T' or 't',  op( B ) = B**T.

  TRANSB = 'C' or 'c',  op( B ) = B**H.

M
  M is INTEGER
  On entry,  M  specifies  the number  of rows  of the  matrix
  op( A )  and of the  matrix  C.  M  must  be at least  zero.

N
  N is INTEGER
  On entry,  N  specifies the number  of columns of the matrix
  op( B ) and the number of columns of the matrix C. N must be
  at least zero.

K
  K is INTEGER
  On entry,  K  specifies  the number of columns of the matrix
  op( A ) and the number of rows of the matrix op( B ). K must
  be at least  zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANSA = 'N' or 'n',  and is  m  otherwise.
  Before entry with  TRANSA = 'N' or 'n',  the leading  m by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by m  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. When  TRANSA = 'N' or 'n' then
  LDA must be at least  max( 1, m ), otherwise  LDA must be at
  least  max( 1, k ).

B
  B is COMPLEX array of DIMENSION ( LDB, kb ), where kb is
  n  when  TRANSB = 'N' or 'n',  and is  k  otherwise.
  Before entry with  TRANSB = 'N' or 'n',  the leading  k by n
  part of the array  B  must contain the matrix  B,  otherwise
  the leading  n by k  part of the array  B  must contain  the
  matrix B.

LDB
```

```
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in the calling (sub) program. When  TRANSB = 'N' or 'n' then
  LDB must be at least  max( 1, k ), otherwise  LDB must be at
  least  max( 1, n ).

BETA
  BETA is COMPLEX
  On entry,  BETA  specifies the scalar  beta.  When  BETA  is
  supplied as zero then C need not be set on input.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).
  Before entry, the leading  m by n  part of the array  C must
  contain the matrix  C,  except when  beta  is zero, in which
  case C need not be set on entry.
  On exit, the array  C  is overwritten by the  m by n  matrix
  ( alpha*op( A )*op( B ) + beta*C ).

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, m ).

SYNOPSIS
   Functions/Subroutines
       subroutine chemm (SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
           LDC)
           CHEMM

Function/Subroutine Documentation
   subroutine chemm (character SIDE, character UPLO, integer M, integer N,
       complex ALPHA, complex, dimension(lda,*) A, integer LDA, complex,
       dimension(ldb,*) B, integer LDB, complex BETA, complex,
       dimension(ldc,*) C, integer LDC)
       CHEMM

Purpose:
   CHEMM  performs one of the matrix-matrix operations

   C := alpha*A*B + beta*C,

   or

   C := alpha*B*A + beta*C,

   where alpha and beta are scalars, A is an hermitian matrix and  B and
   C are m by n matrices.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   On entry,  SIDE  specifies whether  the  hermitian matrix  A
   appears on the  left or right  in the  operation as follows:

   SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

   SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

 UPLO
   UPLO is CHARACTER*1
   On  entry,   UPLO  specifies  whether  the  upper  or  lower
   triangular  part  of  the  hermitian  matrix   A  is  to  be
```

```
  referenced as follows:

  UPLO = 'U' or 'u'   Only the upper triangular part of the
  hermitian matrix is to be referenced.

  UPLO = 'L' or 'l'   Only the lower triangular part of the
  hermitian matrix is to be referenced.

M
  M is INTEGER
  On entry,  M  specifies the number of rows of the matrix  C.
  M  must be at least zero.

N
  N is INTEGER
  On entry, N specifies the number of columns of the matrix C.
  N  must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  m  when  SIDE = 'L' or 'l'  and is n  otherwise.
  Before entry  with  SIDE = 'L' or 'l',  the  m by m  part of
  the array  A  must contain the  hermitian matrix,  such that
  when  UPLO = 'U' or 'u', the leading m by m upper triangular
  part of the array  A  must contain the upper triangular part
  of the  hermitian matrix and the  strictly  lower triangular
  part of  A  is not referenced,  and when  UPLO = 'L' or 'l',
  the leading  m by m  lower triangular part  of the  array  A
  must  contain  the  lower triangular part  of the  hermitian
  matrix and the  strictly upper triangular part of  A  is not
  referenced.

  Before entry  with  SIDE = 'R' or 'r',  the  n by n  part of
  the array  A  must contain the  hermitian matrix,  such that
  when  UPLO = 'U' or 'u', the leading n by n upper triangular
  part of the array  A  must contain the upper triangular part
  of the  hermitian matrix and the  strictly  lower triangular
  part of  A  is not referenced,  and when  UPLO = 'L' or 'l',
  the leading  n by n  lower triangular part  of the  array  A
  must  contain  the  lower triangular part  of the  hermitian
  matrix and the  strictly upper triangular part of  A  is not
  referenced.

  Note that the imaginary parts  of the diagonal elements need
  not be set, they are assumed to be zero.
```

```
LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the  calling (sub) program. When  SIDE = 'L' or 'l'  then
  LDA must be at least  max( 1, m ), otherwise  LDA must be at
  least max( 1, n ).

B
  B is COMPLEX array of DIMENSION ( LDB, n ).
  Before entry, the leading  m by n part of the array  B  must
  contain the matrix B.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.  LDB  must  be  at  least
  max( 1, m ).

BETA
  BETA is COMPLEX
  On entry,  BETA  specifies the scalar  beta.  When  BETA  is
  supplied as zero then C need not be set on input.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).
  Before entry, the leading  m by n  part of the array  C must
  contain the matrix  C,  except when  beta  is zero, in which
  case C need not be set on entry.
  On exit, the array  C  is overwritten by the  m by n updated
  matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, m ).

SYNOPSIS
   Functions/Subroutines
       subroutine cher2k (UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
           LDC)
           CHER2K

Function/Subroutine Documentation
   subroutine cher2k (character UPLO, character TRANS, integer N, integer K,
       complex ALPHA, complex, dimension(lda,*) A, integer LDA, complex,
       dimension(ldb,*) B, integer LDB, real BETA, complex, dimension(ldc,*)
       C, integer LDC)
       CHER2K

Purpose:
   CHER2K  performs one of the hermitian rank 2k operations

   C := alpha*A*B**H + conjg( alpha )*B*A**H + beta*C,

   or

   C := alpha*A**H*B + conjg( alpha )*B**H*A + beta*C,

   where  alpha and beta  are scalars with  beta  real,  C is an  n by n
   hermitian matrix and  A and B  are  n by k matrices in the first case
   and  k by n  matrices in the second case.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On  entry,   UPLO  specifies  whether  the  upper  or  lower
   triangular  part  of the  array  C  is to be  referenced  as follows:

   UPLO = 'U' or 'u'   Only the  upper triangular part of  C
   is to be referenced.

   UPLO = 'L' or 'l'   Only the  lower triangular part of  C
   is to be referenced.

 TRANS

   TRANS is CHARACTER*1
   On entry,  TRANS  specifies the operation to be performed as follows:
```

```
  TRANS = 'N' or 'n'
    C := alpha*A*B**H + conjg( alpha )*B*A**H + beta*C.

  TRANS = 'C' or 'c'
    C := alpha*A**H*B + conjg( alpha )*B**H*A + beta*C.

N
  N is INTEGER
  On entry,  N specifies the order of the matrix C.  N must be
  at least zero.

K
  K is INTEGER
  On entry with  TRANS = 'N' or 'n',  K  specifies  the number
  of  columns  of the  matrices  A and B,  and on  entry  with
  TRANS = 'C' or 'c',  K  specifies  the number of rows of the
  matrices  A and B.  K must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by n  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in  the  calling  (sub)  program.  When  TRANS = 'N' or 'n'
  then  LDA must be at least  max( 1, n ), otherwise  LDA must
  be at least  max( 1, k ).

B
  B is COMPLEX array of DIMENSION ( LDB, kb ), where kb is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  B  must contain the matrix  B,  otherwise
  the leading  k by n  part of the array  B  must contain  the
  matrix B.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.  When  TRANS = 'N' or 'n'
  then  LDB must be at least  max( 1, n ), otherwise  LDB must
```

```
  be at least  max( 1, k ).

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).

  Before entry  with  UPLO = 'U' or 'u',  the leading  n by n
  upper triangular part of the array C must contain the upper
  triangular part  of the  hermitian matrix  and the strictly
  lower triangular part of C is not referenced.  On exit, the
  upper triangular part of the array  C is overwritten by the
  upper triangular part of the updated matrix.

  Before entry  with  UPLO = 'L' or 'l',  the leading  n by n
  lower triangular part of the array C must contain the lower
  triangular part  of the  hermitian matrix  and the strictly
  upper triangular part of C is not referenced.  On exit, the
  lower triangular part of the array  C is overwritten by the
  lower triangular part of the updated matrix.

  Note that the imaginary parts of the diagonal elements need
  not be set,  they are assumed to be zero,  and on exit they
  are set to zero.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, n ).

SYNOPSIS
   Functions/Subroutines
       subroutine cherk (UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
           CHERK

Function/Subroutine Documentation
   subroutine cherk (character UPLO, character TRANS, integer N, integer K,
       real ALPHA, complex, dimension(lda,*) A, integer LDA, real BETA,
       complex, dimension(ldc,*) C, integer LDC)
       CHERK

Purpose:
   CHERK  performs one of the hermitian rank k operations

   C := alpha*A*A**H + beta*C,

   or

   C := alpha*A**H*A + beta*C,

   where  alpha and beta  are  real scalars,  C is an  n by n  hermitian
   matrix and  A  is an  n by k  matrix in the  first case and a  k by n
   matrix in the second case.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On  entry,   UPLO  specifies  whether  the  upper  or  lower
   triangular part of the array C is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the  upper triangular part of  C
   is to be referenced.

   UPLO = 'L' or 'l'   Only the  lower triangular part of  C
   is to be referenced.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'   C := alpha*A*A**H + beta*C.

   TRANS = 'C' or 'c'   C := alpha*A**H*A + beta*C.

 N
   N is INTEGER
   On entry,  N specifies the order of the matrix C.  N must be
   at least zero.
```

```
K
  K is INTEGER
  On entry with  TRANS = 'N' or 'n',  K  specifies  the number
  of  columns   of  the   matrix   A,   and  on   entry   with
  TRANS = 'C' or 'c',  K  specifies  the number of rows of the
  matrix A.  K must be at least zero.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by n  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in  the  calling  (sub)  program.   When  TRANS = 'N' or 'n'
  then  LDA must be at least  max( 1, n ), otherwise  LDA must
  be at least  max( 1, k ).

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).

  Before entry  with  UPLO = 'U' or 'u',  the leading  n by n
  upper triangular part of the array C must contain the upper
  triangular part  of the  hermitian matrix  and the strictly
  lower triangular part of C is not referenced.  On exit, the
  upper triangular part of the array  C is overwritten by the
  upper triangular part of the updated matrix.

  Before entry  with  UPLO = 'L' or 'l',  the leading  n by n
  lower triangular part of the array C must contain the lower
  triangular part  of the  hermitian matrix  and the strictly
  upper triangular part of C is not referenced.  On exit, the
  lower triangular part of the array  C is overwritten by the
  lower triangular part of the updated matrix.

  Note that the imaginary parts of the diagonal elements need
  not be set,  they are assumed to be zero,  and on exit they
```

```
  are set to zero.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, n ).
```

SYNOPSIS
   Functions/Subroutines
       subroutine csymm (SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
           LDC)
           CSYMM

Function/Subroutine Documentation
   subroutine csymm (character SIDE, character UPLO, integer M, integer N,
       complex ALPHA, complex, dimension(lda,*) A, integer LDA, complex,
       dimension(ldb,*) B, integer LDB, complex BETA, complex,
       dimension(ldc,*) C, integer LDC)
       CSYMM

Purpose:
   CSYMM  performs one of the matrix-matrix operations

   C := alpha*A*B + beta*C,

   or

   C := alpha*B*A + beta*C,

   where  alpha and beta are scalars, A is a symmetric matrix and  B and
   C are m by n matrices.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   On entry,  SIDE  specifies whether  the  symmetric matrix  A
   appears on the  left or right  in the  operation as follows:

   SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

   SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

 UPLO

   UPLO is CHARACTER*1
   On  entry,   UPLO  specifies  whether  the  upper  or  lower
   triangular  part  of  the  symmetric  matrix   A  is  to  be
   referenced as follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of the
   symmetric matrix is to be referenced.
```

```
  UPLO = 'L' or 'l'   Only the lower triangular part of the
  symmetric matrix is to be referenced.

M
  M is INTEGER
  On entry,  M  specifies the number of rows of the matrix  C.
  M  must be at least zero.

N
  N is INTEGER
  On entry, N specifies the number of columns of the matrix C.
  N  must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  m  when  SIDE = 'L' or 'l'  and is n  otherwise.

  Before entry  with  SIDE = 'L' or 'l',  the  m by m  part of
  the array  A  must contain the  symmetric matrix,  such that
  when  UPLO = 'U' or 'u', the leading m by m upper triangular
  part of the array  A  must contain the upper triangular part
  of the  symmetric matrix and the  strictly  lower triangular
  part of  A  is not referenced,  and when  UPLO = 'L' or 'l',
  the leading  m by m  lower triangular part  of the  array  A
  must  contain  the  lower triangular part  of the  symmetric
  matrix and the  strictly upper triangular part of  A  is not
  referenced.

  Before entry  with  SIDE = 'R' or 'r',  the  n by n  part of
  the array  A  must contain the  symmetric matrix,  such that
  when  UPLO = 'U' or 'u', the leading n by n upper triangular
  part of the array  A  must contain the upper triangular part
  of the  symmetric matrix and the  strictly  lower triangular
  part of  A  is not referenced,  and when  UPLO = 'L' or 'l',
  the leading  n by n  lower triangular part  of the  array  A
  must  contain  the  lower triangular part  of the  symmetric
  matrix and the  strictly upper triangular part of  A  is not
  referenced.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the  calling (sub) program. When  SIDE = 'L' or 'l'  then
  LDA must be at least  max( 1, m ), otherwise  LDA must be at
  least max( 1, n ).
```

```
B
  B is COMPLEX array of DIMENSION ( LDB, n ).
  Before entry, the leading  m by n part of the array  B  must
  contain the matrix B.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.  LDB  must  be  at  least
  max( 1, m ).

BETA
  BETA is COMPLEX
  On entry,  BETA  specifies the scalar  beta.  When  BETA  is
  supplied as zero then C need not be set on input.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).

  Before entry, the leading  m by n  part of the array  C must
  contain the matrix  C,  except when  beta  is zero, in which
  case C need not be set on entry.
  On exit, the array C is overwritten by the m by n updated matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, m ).

SYNOPSIS
   Functions/Subroutines
       subroutine csyr2k (UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB, BETA, C,
           LDC)
           CSYR2K

Function/Subroutine Documentation
   subroutine csyr2k (character UPLO, character TRANS, integer N, integer K,
       complex ALPHA, complex, dimension(lda,*) A, integer LDA, complex,
       dimension(ldb,*) B, integer LDB, complex BETA, complex,
       dimension(ldc,*) C, integer LDC)
```

```
      CSYR2K

Purpose:
   CSYR2K  performs one of the symmetric rank 2k operations

   C := alpha*A*B**T + alpha*B*A**T + beta*C,

   or

   C := alpha*A**T*B + alpha*B**T*A + beta*C,

   where  alpha and beta  are scalars,  C is an  n by n symmetric matrix
   and  A and B  are  n by k  matrices  in the  first  case  and  k by n
   matrices in the second case.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On  entry,   UPLO  specifies  whether  the  upper  or  lower
   triangular part of the array C is to be referenced as follows:

   UPLO = 'U' or 'u'   Only the  upper triangular part of  C
   is to be referenced.

   UPLO = 'L' or 'l'   Only the  lower triangular part of  C
   is to be referenced.

 TRANS
   TRANS is CHARACTER*1
   On entry, TRANS specifies the operation to be performed as follows:

   TRANS = 'N' or 'n'    C := alpha*A*B**T + alpha*B*A**T + beta*C.

   TRANS = 'T' or 't'    C := alpha*A**T*B + alpha*B**T*A + beta*C.

 N
   N is INTEGER
   On entry,  N specifies the order of the matrix C.  N must be
   at least zero.

 K
   K is INTEGER
   On entry with  TRANS = 'N' or 'n',  K  specifies  the number
   of  columns  of the  matrices  A and B,  and on  entry  with
   TRANS = 'T' or 't',  K  specifies  the number of rows of the
   matrices  A and B.  K must be at least zero.

 ALPHA
   ALPHA is COMPLEX
```

```
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.

  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by n  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in  the  calling  (sub)  program.   When  TRANS = 'N' or 'n'
  then  LDA must be at least  max( 1, n ), otherwise  LDA must
  be at least  max( 1, k ).

B
  B is COMPLEX array of DIMENSION ( LDB, kb ), where kb is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  B  must contain the matrix  B,  otherwise
  the leading  k by n  part of the array  B  must contain  the
  matrix B.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
  in  the  calling  (sub)  program.   When  TRANS = 'N' or 'n'
  then  LDB must be at least  max( 1, n ), otherwise  LDB must
  be at least  max( 1, k ).

BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).

  Before entry  with  UPLO = 'U' or 'u',  the leading  n by n
  upper triangular part of the array C must contain the upper
  triangular part  of the  symmetric matrix  and the strictly
  lower triangular part of C is not referenced.  On exit, the
  upper triangular part of the array  C is overwritten by the
  upper triangular part of the updated matrix.

  Before entry  with  UPLO = 'L' or 'l',  the leading  n by n
  lower triangular part of the array C must contain the lower
  triangular part  of the  symmetric matrix  and the strictly
```

```
  upper triangular part of C is not referenced.  On exit, the
  lower triangular part of the array  C is overwritten by the
  lower triangular part of the updated matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, n ).

SYNOPSIS
   Functions/Subroutines
       subroutine csyrk (UPLO, TRANS, N, K, ALPHA, A, LDA, BETA, C, LDC)
           CSYRK

Function/Subroutine Documentation
   subroutine csyrk (character UPLO, character TRANS, integer N, integer K,
       complex ALPHA, complex, dimension(lda,*) A, integer LDA, complex BETA,
       complex, dimension(ldc,*) C, integer LDC)
       CSYRK

Purpose:
   CSYRK  performs one of the symmetric rank k operations

   C := alpha*A*A**T + beta*C,

   or

   C := alpha*A**T*A + beta*C,

   where  alpha and beta  are scalars,  C is an  n by n symmetric matrix
   and  A  is an  n by k  matrix in the first case and a  k by n  matrix
   in the second case.

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  On  entry,  UPLO  specifies  whether  the  upper  or  lower
  triangular part of the array C is to be referenced as follows:

  UPLO = 'U' or 'u'   Only the  upper triangular part of  C
  is to be referenced.

  UPLO = 'L' or 'l'   Only the  lower triangular part of  C
  is to be referenced.

TRANS
  TRANS is CHARACTER*1
  On entry,  TRANS  specifies the operation to be performed as follows:

  TRANS = 'N' or 'n'   C := alpha*A*A**T + beta*C.

  TRANS = 'T' or 't'   C := alpha*A**T*A + beta*C.

N
  N is INTEGER
  On entry,  N specifies the order of the matrix C.  N must be
  at least zero.

K
  K is INTEGER
  On entry with  TRANS = 'N' or 'n',  K  specifies  the number
  of  columns  of  the  matrix  A,  and  on  entry  with
  TRANS = 'T' or 't',  K  specifies  the number of rows of the
  matrix A.  K must be at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.

A
  A is COMPLEX array of DIMENSION ( LDA, ka ), where ka is
  k  when  TRANS = 'N' or 'n',  and is  n  otherwise.

  Before entry with  TRANS = 'N' or 'n',  the  leading  n by k
  part of the array  A  must contain the matrix  A,  otherwise
  the leading  k by n  part of the array  A  must contain  the
  matrix A.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in  the  calling  (sub)  program.  When  TRANS = 'N' or 'n'
  then  LDA must be at least  max( 1, n ), otherwise  LDA must
  be at least  max( 1, k ).
```

```
BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta.

C
  C is COMPLEX array of DIMENSION ( LDC, n ).

  Before entry  with  UPLO = 'U' or 'u',  the leading  n by n
  upper triangular part of the array C must contain the upper
  triangular part  of the  symmetric matrix  and the strictly
  lower triangular part of C is not referenced.  On exit, the
  upper triangular part of the array  C is overwritten by the
  upper triangular part of the updated matrix.

  Before entry  with  UPLO = 'L' or 'l',  the leading  n by n
  lower triangular part of the array C must contain the lower
  triangular part  of the  symmetric matrix  and the strictly
  upper triangular part of C is not referenced.  On exit, the
  lower triangular part of the array  C is overwritten by the
  lower triangular part of the updated matrix.

LDC
  LDC is INTEGER
  On entry, LDC specifies the first dimension of C as declared
  in  the  calling  (sub)  program.  LDC  must  be  at  least
  max( 1, n ).

SYNOPSIS
   Functions/Subroutines
       subroutine ctrmm (SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
           LDB)
           CTRMM

Function/Subroutine Documentation
   subroutine ctrmm (character SIDE, character UPLO, character TRANSA,
```

```
      character DIAG, integer M, integer N, complex ALPHA, complex,
      dimension(lda,*) A, integer LDA, complex, dimension(ldb,*) B, integer
      LDB)
      CTRMM

Purpose:
   CTRMM  performs one of the matrix-matrix operations

   B := alpha*op( A )*B,   or   B := alpha*B*op( A )

   where  alpha  is a scalar,  B  is an m by n matrix,  A  is a unit, or
   non-unit,  upper or lower triangular matrix  and  op( A )  is one  of

   op( A ) = A   or   op( A ) = A**T   or   op( A ) = A**H.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   On entry,  SIDE specifies whether  op( A ) multiplies B from
   the left or right as follows:

   SIDE = 'L' or 'l'   B := alpha*op( A )*B.

   SIDE = 'R' or 'r'   B := alpha*B*op( A ).

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the matrix A is an upper or
   lower triangular matrix as follows:

   UPLO = 'U' or 'u'   A is an upper triangular matrix.

   UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANSA
   TRANSA is CHARACTER*1
   On entry, TRANSA specifies the form of op( A ) to be used in
   the matrix multiplication as follows:

   TRANSA = 'N' or 'n'   op( A ) = A.

   TRANSA = 'T' or 't'   op( A ) = A**T.

   TRANSA = 'C' or 'c'   op( A ) = A**H.

 DIAG
   DIAG is CHARACTER*1
   On entry, DIAG specifies whether or not A is unit triangular
   as follows:
```

```
  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

M
  M is INTEGER
  On entry, M specifies the number of rows of B. M must be at
  least zero.

N
  N is INTEGER
  On entry, N specifies the number of columns of B.  N must be
  at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry,  ALPHA specifies the scalar  alpha. When  alpha is
  zero then  A is not referenced and  B need not be set before entry.

A
  A is COMPLEX array of DIMENSION ( LDA, k ), where k is m
  when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R' or 'r'.

  Before entry  with  UPLO = 'U' or 'u',  the  leading  k by k
  upper triangular part of the array  A must contain the upper
  triangular matrix  and the strictly lower triangular part of
  A is not referenced.

  Before entry  with  UPLO = 'L' or 'l',  the  leading  k by k
  lower triangular part of the array  A must contain the lower
  triangular matrix  and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u',  the diagonal elements of
  A  are not referenced either,  but are assumed to be  unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program.  When  SIDE = 'L' or 'l'  then
  LDA  must be at least  max( 1, m ),  when  SIDE = 'R' or 'r'
  then LDA must be at least max( 1, n ).

B
  B is COMPLEX array of DIMENSION ( LDB, n ).
  Before entry,  the leading  m by n part of the array  B must
  contain the matrix  B,  and  on exit  is overwritten  by the
  transformed matrix.
```

```
 LDB
   LDB is INTEGER
   On entry, LDB specifies the first dimension of B as declared
   in  the  calling  (sub)  program.   LDB  must  be  at  least
   max( 1, m ).

SYNOPSIS
   Functions/Subroutines
       subroutine ctrsm (SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
           LDB)
           CTRSM

Function/Subroutine Documentation
   subroutine ctrsm (character SIDE, character UPLO, character TRANSA,
       character DIAG, integer M, integer N, complex ALPHA, complex,
       dimension(lda,*) A, integer LDA, complex, dimension(ldb,*) B, integer
       LDB)
       CTRSM

Purpose:
```

```
  CTRSM  solves one of the matrix equations

  op( A )*X = alpha*B,   or   X*op( A ) = alpha*B,

  where alpha is a scalar, X and B are m by n matrices, A is a unit, or
  non-unit,  upper or lower triangular matrix  and  op( A )  is one  of

  op( A ) = A   or   op( A ) = A**T   or   op( A ) = A**H.

  The matrix X is overwritten on B.

Parameters:

 SIDE
  SIDE is CHARACTER*1
  On entry, SIDE specifies whether op( A ) appears on the left
  or right of X as follows:

  SIDE = 'L' or 'l'   op( A )*X = alpha*B.

  SIDE = 'R' or 'r'   X*op( A ) = alpha*B.

 UPLO
  UPLO is CHARACTER*1
  On entry, UPLO specifies whether the matrix A is an upper or
  lower triangular matrix as follows:

  UPLO = 'U' or 'u'   A is an upper triangular matrix.

  UPLO = 'L' or 'l'   A is a lower triangular matrix.

 TRANSA
  TRANSA is CHARACTER*1
  On entry, TRANSA specifies the form of op( A ) to be used in
  the matrix multiplication as follows:

  TRANSA = 'N' or 'n'   op( A ) = A.

  TRANSA = 'T' or 't'   op( A ) = A**T.

  TRANSA = 'C' or 'c'   op( A ) = A**H.

 DIAG
  DIAG is CHARACTER*1
  On entry, DIAG specifies whether or not A is unit triangular
  as follows:

  DIAG = 'U' or 'u'   A is assumed to be unit triangular.

  DIAG = 'N' or 'n'   A is not assumed to be unit triangular.
```

```
M
  M is INTEGER
  On entry, M specifies the number of rows of B. M must be at
  least zero.

N
  N is INTEGER
  On entry, N specifies the number of columns of B.  N must be
  at least zero.

ALPHA
  ALPHA is COMPLEX
  On entry,  ALPHA specifies the scalar  alpha. When  alpha is
  zero then  A is not referenced and  B need not be set before entry.

A
  A is COMPLEX array of DIMENSION ( LDA, k ),
  where k is m when SIDE = 'L' or 'l'
  and k is n when SIDE = 'R' or 'r'.

  Before entry  with  UPLO = 'U' or 'u',  the  leading  k by k
  upper triangular part of the array  A must contain the upper
  triangular matrix  and the strictly lower triangular part of
  A is not referenced.

  Before entry  with  UPLO = 'L' or 'l',  the  leading  k by k
  lower triangular part of the array  A must contain the lower
  triangular matrix  and the strictly upper triangular part of
  A is not referenced.

  Note that when  DIAG = 'U' or 'u',  the diagonal elements of
  A  are not referenced either,  but are assumed to be  unity.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program.  When  SIDE = 'L' or 'l'  then
  LDA  must be at least  max( 1, m ),  when  SIDE = 'R' or 'r'
  then LDA must be at least max( 1, n ).

B
  B is COMPLEX array of DIMENSION ( LDB, n ).
  Before entry,  the leading  m by n part of the array  B must
  contain  the  right-hand  side  matrix  B,  and  on exit  is
  overwritten by the solution matrix  X.

LDB
  LDB is INTEGER
  On entry, LDB specifies the first dimension of B as declared
```

```
in the calling (sub) program. LDB must be at least
max( 1, m ).
```

 NAME
      ZGEMM - perform one of the matrix-matrix operations   C :=
      alpha*op( A )*op( B ) + beta*C,

 SYNOPSIS
      SUBROUTINE ZGEMM ( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA,
                       B, LDB, BETA, C, LDC )

          CHARACTER*1  TRANSA, TRANSB

          INTEGER      M, N, K, LDA, LDB, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZGEMM  performs one of the matrix-matrix operations

      where  op( X ) is one of

         op( X ) = X   or   op( X ) = X'   or   op( X ) = conjg(
      X' ),

      alpha and beta are scalars, and A, B and C are matrices,
      with op( A ) an m by k matrix,  op( B )  a  k by n matrix
      and  C an m by n matrix.

 PARAMETERS
      TRANSA - CHARACTER*1.  On entry, TRANSA specifies the form
      of op( A ) to be used in the matrix multiplication as fol-
      lows:

      TRANSA = 'N' or 'n',  op( A ) = A.

      TRANSA = 'T' or 't',  op( A ) = A'.

      TRANSA = 'C' or 'c',  op( A ) = conjg( A' ).

      Unchanged on exit.

      TRANSB - CHARACTER*1.  On entry, TRANSB specifies the form
      of op( B ) to be used in the matrix multiplication as fol-
      lows:
```

```
     TRANSB = 'N' or 'n',  op( B ) = B.

     TRANSB = 'T' or 't',  op( B ) = B'.

     TRANSB = 'C' or 'c',  op( B ) = conjg( B' ).

     Unchanged on exit.

     M      - INTEGER.
              On entry,  M  specifies  the number  of rows  of the
              matrix op( A )  and of the  matrix  C.  M  must  be
              at least  zero.  Unchanged on exit.

     N      - INTEGER.
              On entry,  N  specifies the number  of columns of the
              matrix op( B ) and the number of columns of the
              matrix C. N must be at least zero.  Unchanged on
              exit.

     K      - INTEGER.
              On entry,  K  specifies  the number of columns of the
              matrix op( A ) and the number of rows of the matrix
              op( B ). K must be at least  zero.  Unchanged on
              exit.

     ALPHA  - COMPLEX*16      .
              On entry, ALPHA specifies the scalar alpha.
              Unchanged on exit.

ka is
     A      -
               COMPLEX*16       array of DIMENSION ( LDA, ka ), where
              k  when  TRANSA = 'N' or 'n',  and is  m  otherwise.
              Before entry with  TRANSA = 'N' or 'n',  the leading
              m by k part of the array  A  must contain the matrix
              A,  otherwise the leading  k by m  part of the array
              A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
              On entry, LDA specifies the first dimension of A as
              declared in the calling (sub) program. When  TRANSA =
              'N' or 'n' then LDA must be at least  max( 1, m ),
              otherwise  LDA must be at least  max( 1, k ).
              Unchanged on exit.

kb is
     B      -
               COMPLEX*16       array of DIMENSION ( LDB, kb ), where
              n  when  TRANSB = 'N' or 'n',  and is  k  otherwise.
```

```
            Before entry with  TRANSB = 'N' or 'n',  the leading
            k by n part of the array  B  must contain the matrix
            B,  otherwise the leading  n by k  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

      LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in the calling (sub) program. When  TRANSB =
            'N' or 'n' then LDB must be at least  max( 1, k ),

            otherwise  LDB must be at least  max( 1, n ).
            Unchanged on exit.

      BETA   - COMPLEX*16      .
            On entry,  BETA  specifies the scalar  beta.  When
            BETA  is supplied as zero then C need not be set on
            input.  Unchanged on exit.

      C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry, the leading  m by n  part of the array
            C must contain the matrix  C,  except when  beta  is
            zero, in which case C need not be set on entry.  On
            exit, the array  C  is overwritten by the  m by n
            matrix ( alpha*op( A )*op( B ) + beta*C ).

      LDC    - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZHEMM - perform one of the matrix-matrix operations
              C := alpha*A*B + beta*C,

 SYNOPSIS
      SUBROUTINE ZHEMM ( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1  SIDE, UPLO

          INTEGER      M, N, LDA, LDB, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZHEMM  performs one of the matrix-matrix operations

      or

         C := alpha*B*A + beta*C,

      where alpha and beta are scalars, A is an hermitian matrix
      and  B and C are m by n matrices.

 PARAMETERS
      SIDE   - CHARACTER*1.
             On entry,  SIDE  specifies whether  the  hermitian
             matrix  A appears on the  left or right  in the
             operation as follows:

             SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

             SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

             Unchanged on exit.

      UPLO   - CHARACTER*1.
             On  entry,   UPLO  specifies  whether  the  upper  or
             lower triangular  part  of  the  hermitian  matrix
             A  is  to  be referenced as follows:

             UPLO = 'U' or 'u'   Only the upper triangular part of
             the hermitian matrix is to be referenced.

             UPLO = 'L' or 'l'   Only the lower triangular part of
             the hermitian matrix is to be referenced.
```

```
        Unchanged on exit.

M       - INTEGER.
        On entry,  M  specifies the number of rows of the
        matrix  C.  M  must be at least zero.  Unchanged on
        exit.

N       - INTEGER.
        On entry, N specifies the number of columns of the
        matrix C.  N  must be at least zero.  Unchanged on
        exit.

ALPHA   - COMPLEX*16      .
        On entry, ALPHA specifies the scalar alpha.
        Unchanged on exit.

A       -
         COMPLEX*16       array of DIMENSION ( LDA, ka ), where
        ka is m  when  SIDE = 'L' or 'l'  and is n  otherwise.
        Before entry  with  SIDE = 'L' or 'l',  the  m by m
        part of the array  A  must contain the  hermitian
        matrix,  such that when  UPLO = 'U' or 'u', the lead-
        ing m by m upper triangular part of the array  A
        must contain the upper triangular part of the  hermi-
        tian matrix and the  strictly  lower triangular part
        of  A  is not referenced,  and when  UPLO = 'L' or
        'l', the leading  m by m  lower triangular part  of
        the  array  A must  contain  the  lower triangular
        part  of the  hermitian matrix and the  strictly
        upper triangular part of  A  is not referenced.
        Before entry  with  SIDE = 'R' or 'r',  the  n by n
        part of the array  A  must contain the  hermitian
        matrix,  such that when  UPLO = 'U' or 'u', the lead-
        ing n by n upper triangular part of the array  A
        must contain the upper triangular part of the  hermi-
        tian matrix and the  strictly  lower triangular part
        of  A  is not referenced,  and when  UPLO = 'L' or
        'l', the leading  n by n  lower triangular part  of
        the  array  A must  contain  the  lower triangular
        part  of the  hermitian matrix and the  strictly
        upper triangular part of  A  is not referenced.  Note
        that the imaginary parts  of the diagonal elements
        need not be set, they are assumed to be zero.
        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the  calling (sub) program. When  SIDE =
        'L' or 'l'  then LDA must be at least  max( 1, m ),
```

```
            otherwise  LDA must be at least max( 1, n ).
            Unchanged on exit.

      B     - COMPLEX*16       array of DIMENSION ( LDB, n ).

            Before entry, the leading  m by n part of the array
            B  must contain the matrix B.  Unchanged on exit.

      LDB   - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   LDB
            must  be  at  least max( 1, m ).  Unchanged on exit.

      BETA  - COMPLEX*16      .
            On entry,  BETA  specifies the scalar  beta.  When
            BETA  is supplied as zero then C need not be set on
            input.  Unchanged on exit.

      C     - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry, the leading  m by n  part of the array
            C must contain the matrix  C,  except when  beta  is
            zero, in which case C need not be set on entry.  On
            exit, the array  C  is overwritten by the  m by n
            updated matrix.

      LDC   - INTEGER.
            On entry, LDC specifies the first dimension of C as
            declared in  the  calling  (sub)  program.   LDC
            must  be  at  least max( 1, m ).  Unchanged on exit.
```

 NAME
      ZHER2K - perform one of the hermitian rank 2k operations   C
      := alpha*A*conjg( B' ) + conjg( alpha )*B*conjg( A' ) +
      beta*C,

 SYNOPSIS
      SUBROUTINE ZHER2K( UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1    UPLO, TRANS

          INTEGER        N, K, LDA, LDB, LDC

          DOUBLE         PRECISION BETA

          COMPLEX*16     ALPHA

          COMPLEX*16     A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZHER2K  performs one of the hermitian rank 2k operations

      or
```

```
   C := alpha*conjg( A' )*B + conjg( alpha )*conjg( B' )*A +
beta*C,

where  alpha and beta  are scalars with  beta  real,  C is
an  n by n hermitian matrix and  A and B  are  n by k
matrices in the first case and  k by n  matrices in the
second case.

PARAMETERS
     UPLO   - CHARACTER*1.
            On  entry,   UPLO  specifies  whether  the  upper  or
            lower triangular  part  of the  array  C  is to be
            referenced  as follows:

            UPLO = 'U' or 'u'   Only the  upper triangular part
            of  C is to be referenced.

            UPLO = 'L' or 'l'   Only the  lower triangular part
            of  C is to be referenced.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'    C := alpha*A*conjg( B' )

            + conjg( alpha )*B*conjg( A' ) + beta*C.

            TRANS = 'C' or 'c'    C := alpha*conjg( A' )*B
            + conjg( alpha )*conjg( B' )*A + beta*C.

            Unchanged on exit.

     N      - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.

     K      - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns  of the  matrices  A and B,  and
            on  entry  with TRANS = 'C' or 'c',  K  specifies
            the number of rows of the matrices  A and B.  K must
            be at least zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.
```

```
ka is
     A      -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

kb is
     B      -
             COMPLEX*16       array of DIMENSION ( LDB, kb ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  B  must contain the matrix
            B,  otherwise the leading  k by n  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDB must be at least  max(
            1, n ), otherwise  LDB must be at least  max( 1, k ).

            Unchanged on exit.

     BETA   - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

     C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  hermitian
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  hermitian matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
```

```
            array  C is overwritten by the lower triangular part
            of the updated matrix.  Note that the imaginary parts
            of the diagonal elements need not be set,  they are
            assumed to be zero,  and on exit they are set to
            zero.

      LDC    - INTEGER.
             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, n ).  Unchanged on exit.
```

 NAME
      ZHERK - perform one of the hermitian rank k operations   C
      := alpha*A*conjg( A' ) + beta*C,

 SYNOPSIS
      SUBROUTINE ZHERK ( UPLO, TRANS, N, K, ALPHA, A, LDA, BETA,
                         C, LDC )

          CHARACTER*1  UPLO, TRANS

          INTEGER      N, K, LDA, LDC

          DOUBLE       PRECISION ALPHA, BETA

          COMPLEX*16   A( LDA, * ), C( LDC, * )

 PURPOSE
      ZHERK  performs one of the hermitian rank k operations

      or

         C := alpha*conjg( A' )*A + beta*C,

      where  alpha and beta  are  real scalars,  C is an  n by n
      hermitian matrix and  A  is an  n by k  matrix in the  first
      case and a  k by n matrix in the second case.

 PARAMETERS
      UPLO   - CHARACTER*1.
             On  entry,   UPLO  specifies  whether  the  upper  or
             lower triangular  part  of the  array  C  is to be
             referenced  as follows:

             UPLO = 'U' or 'u'   Only the  upper triangular part
             of  C is to be referenced.

             UPLO = 'L' or 'l'   Only the  lower triangular part
             of  C is to be referenced.

             Unchanged on exit.

      TRANS  - CHARACTER*1.
             On entry,  TRANS  specifies the operation to be per-
             formed as follows:

             TRANS = 'N' or 'n'   C := alpha*A*conjg( A' ) +
             beta*C.
```

```
            TRANS = 'C' or 'c'   C := alpha*conjg( A' )*A +
            beta*C.

            Unchanged on exit.

      N     - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.

      K     - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns   of  the   matrix   A,   and  on
            entry   with TRANS = 'C' or 'c',  K  specifies  the
            number of rows of the matrix A.  K must be at least
            zero.  Unchanged on exit.

      ALPHA - DOUBLE PRECISION.
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
      A     -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

      BETA  - DOUBLE PRECISION.
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

      C     - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  hermitian
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
```

```
            triangular part of the array C must contain the lower
            triangular part  of the  hermitian matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.  Note that the imaginary parts

            of the diagonal elements need not be set,  they are
            assumed to be zero,  and on exit they are set to
            zero.

      LDC    - INTEGER.
             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, n ).  Unchanged on exit.
```

 NAME
      ZSYMM - perform one of the matrix-matrix operations   C :=
      alpha*A*B + beta*C,

 SYNOPSIS
      SUBROUTINE ZSYMM ( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1  SIDE, UPLO

          INTEGER      M, N, LDA, LDB, LDC

          COMPLEX*16   ALPHA, BETA

          COMPLEX*16   A( LDA, * ), B( LDB, * ), C( LDC, * )

 PURPOSE
      ZSYMM  performs one of the matrix-matrix operations

      or

         C := alpha*B*A + beta*C,

      where  alpha and beta are scalars, A is a symmetric matrix
      and  B and C are m by n matrices.

 PARAMETERS
```

```
     SIDE   - CHARACTER*1.
            On entry,  SIDE  specifies whether  the  symmetric
            matrix  A appears on the  left or right  in the
            operation as follows:

            SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

            SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On  entry,   UPLO  specifies  whether  the  upper  or
            lower triangular  part  of  the  symmetric  matrix
            A  is  to  be referenced as follows:

            UPLO = 'U' or 'u'   Only the upper triangular part of
            the symmetric matrix is to be referenced.

            UPLO = 'L' or 'l'   Only the lower triangular part of
            the symmetric matrix is to be referenced.

            Unchanged on exit.

     M      - INTEGER.
            On entry,  M  specifies the number of rows of the
            matrix  C.  M  must be at least zero.  Unchanged on
            exit.

     N      - INTEGER.
            On entry, N specifies the number of columns of the
            matrix C.  N  must be at least zero.  Unchanged on
            exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

 ka is
     A      -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            m  when  SIDE = 'L' or 'l'  and is n  otherwise.
            Before entry  with  SIDE = 'L' or 'l',  the  m by m
            part of the array  A  must contain the  symmetric
            matrix,  such that when  UPLO = 'U' or 'u', the lead-
            ing m by m upper triangular part of the array  A
            must contain the upper triangular part of the  sym-
            metric matrix and the  strictly  lower triangular
            part of  A  is not referenced,  and when  UPLO = 'L'
            or 'l', the leading  m by m  lower triangular part
```

```
        of the  array  A must  contain  the  lower triangular
        part  of the  symmetric matrix and the  strictly
        upper triangular part of  A  is not referenced.
        Before entry  with  SIDE = 'R' or 'r',  the  n by n
        part of the array  A  must contain the  symmetric
        matrix,  such that when  UPLO = 'U' or 'u', the lead-
        ing n by n upper triangular part of the array  A
        must contain the upper triangular part of the  sym-
        metric matrix and the  strictly  lower triangular
        part of  A  is not referenced,  and when  UPLO = 'L'
        or 'l', the leading  n by n  lower triangular part
        of the  array  A must  contain  the  lower triangular
        part  of the  symmetric matrix and the  strictly
        upper triangular part of  A  is not referenced.
        Unchanged on exit.

LDA     - INTEGER.
        On entry, LDA specifies the first dimension of A as
        declared in the  calling (sub) program. When  SIDE =
        'L' or 'l'  then LDA must be at least  max( 1, m ),
        otherwise  LDA must be at least max( 1, n ).
        Unchanged on exit.

B       - COMPLEX*16       array of DIMENSION ( LDB, n ).
        Before entry, the leading  m by n part of the array
        B  must contain the matrix B.  Unchanged on exit.

LDB     - INTEGER.
        On entry, LDB specifies the first dimension of B as
        declared in  the  calling  (sub)  program.   LDB
        must  be  at  least max( 1, m ).  Unchanged on exit.

BETA    - COMPLEX*16      .
        On entry,  BETA  specifies the scalar  beta.  When
        BETA  is supplied as zero then C need not be set on
        input.  Unchanged on exit.

C       - COMPLEX*16       array of DIMENSION ( LDC, n ).
        Before entry, the leading  m by n  part of the array
        C must contain the matrix  C,  except when  beta  is
        zero, in which case C need not be set on entry.  On
        exit, the array  C  is overwritten by the  m by n
        updated matrix.

LDC     - INTEGER.
        On entry, LDC specifies the first dimension of C as
        declared in  the  calling  (sub)  program.   LDC
        must  be  at  least max( 1, m ).  Unchanged on exit.

 NAME
      ZSYR2K - perform one of the symmetric rank 2k operations   C
      := alpha*A*B' + alpha*B*A' + beta*C,

 SYNOPSIS
      SUBROUTINE ZSYR2K( UPLO, TRANS, N, K, ALPHA, A, LDA, B, LDB,
                         BETA, C, LDC )

          CHARACTER*1    UPLO, TRANS

          INTEGER        N, K, LDA, LDB, LDC

          COMPLEX*16     ALPHA, BETA
```

```
         COMPLEX*16     A( LDA, * ), B( LDB, * ), C( LDC, * )

PURPOSE
     ZSYR2K  performs one of the symmetric rank 2k operations

     or

        C := alpha*A'*B + alpha*B'*A + beta*C,

     where  alpha and beta  are scalars,  C is an  n by n sym-
     metric matrix and  A and B  are  n by k  matrices  in the
     first  case  and  k by n matrices in the second case.

PARAMETERS
     UPLO   - CHARACTER*1.
            On  entry,  UPLO  specifies  whether  the  upper  or
            lower triangular  part  of the  array  C  is to be
            referenced  as follows:

            UPLO = 'U' or 'u'   Only the  upper triangular part
            of  C is to be referenced.

            UPLO = 'L' or 'l'   Only the  lower triangular part
            of  C is to be referenced.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'    C := alpha*A*B' + alpha*B*A' +
            beta*C.

            TRANS = 'T' or 't'    C := alpha*A'*B + alpha*B'*A +
            beta*C.

            Unchanged on exit.

     N      - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.

     K      - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns  of the  matrices  A and B,  and
            on  entry  with TRANS = 'T' or 't',  K  specifies
            the number of rows of the matrices  A and B.  K must
            be at least zero.  Unchanged on exit.
```

```
     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

ka is
     A      -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

kb is
     B      -
             COMPLEX*16       array of DIMENSION ( LDB, kb ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  B  must contain the matrix
            B,  otherwise the leading  k by n  part of the array
            B  must contain  the matrix B.  Unchanged on exit.

     LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDB must be at least  max(
            1, n ), otherwise  LDB must be at least  max( 1, k ).
            Unchanged on exit.

     BETA   - COMPLEX*16      .
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

     C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  symmetric
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
```

```
            triangular part  of the  symmetric matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.

      LDC    - INTEGER.
             On entry, LDC specifies the first dimension of C as
             declared in  the  calling  (sub)  program.   LDC
             must  be  at  least max( 1, n ).  Unchanged on exit.
```

 NAME
      ZSYRK - perform one of the symmetric rank k operations   C
      := alpha*A*A' + beta*C,

 SYNOPSIS
```

```
     SUBROUTINE ZSYRK ( UPLO, TRANS, N, K, ALPHA, A, LDA, BETA,
                        C, LDC )

         CHARACTER*1  UPLO, TRANS

         INTEGER      N, K, LDA, LDC

         COMPLEX*16   ALPHA, BETA

         COMPLEX*16   A( LDA, * ), C( LDC, * )

PURPOSE
     ZSYRK  performs one of the symmetric rank k operations

     or

        C := alpha*A'*A + beta*C,

     where  alpha and beta  are scalars,  C is an  n by n sym-
     metric matrix and  A  is an  n by k  matrix in the first
     case and a  k by n  matrix in the second case.

PARAMETERS
     UPLO   - CHARACTER*1.
            On  entry,  UPLO  specifies  whether  the  upper  or
            lower triangular  part  of the  array  C  is to be
            referenced  as follows:

            UPLO = 'U' or 'u'   Only the  upper triangular part
            of  C is to be referenced.

            UPLO = 'L' or 'l'   Only the  lower triangular part
            of  C is to be referenced.

            Unchanged on exit.

     TRANS  - CHARACTER*1.
            On entry,  TRANS  specifies the operation to be per-
            formed as follows:

            TRANS = 'N' or 'n'   C := alpha*A*A' + beta*C.

            TRANS = 'T' or 't'   C := alpha*A'*A + beta*C.

            Unchanged on exit.

     N      - INTEGER.
            On entry,  N specifies the order of the matrix C.  N
            must be at least zero.  Unchanged on exit.
```

```
     K      - INTEGER.
            On entry with  TRANS = 'N' or 'n',  K  specifies  the
            number of  columns   of  the   matrix   A,   and  on
            entry   with TRANS = 'T' or 't',  K  specifies  the
            number of rows of the matrix A.  K must be at least
            zero.  Unchanged on exit.

     ALPHA  - COMPLEX*16      .
            On entry, ALPHA specifies the scalar alpha.
            Unchanged on exit.

 ka is
     A      -
             COMPLEX*16       array of DIMENSION ( LDA, ka ), where
            k  when  TRANS = 'N' or 'n',  and is  n  otherwise.
            Before entry with  TRANS = 'N' or 'n',  the  leading
            n by k part of the array  A  must contain the matrix
            A,  otherwise the leading  k by n  part of the array
            A  must contain  the matrix A.  Unchanged on exit.

     LDA    - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in  the  calling  (sub)  program.   When
            TRANS = 'N' or 'n' then  LDA must be at least  max(
            1, n ), otherwise  LDA must be at least  max( 1, k ).
            Unchanged on exit.

     BETA   - COMPLEX*16      .
            On entry, BETA specifies the scalar beta.  Unchanged
            on exit.

     C      - COMPLEX*16       array of DIMENSION ( LDC, n ).
            Before entry  with  UPLO = 'U' or 'u',  the leading
            n by n upper triangular part of the array C must con-
            tain the upper triangular part  of the  symmetric
            matrix  and the strictly lower triangular part of C
            is not referenced.  On exit, the upper triangular
            part of the array  C is overwritten by the upper tri-
            angular part of the updated matrix.  Before entry
            with  UPLO = 'L' or 'l',  the leading  n by n lower
            triangular part of the array C must contain the lower
            triangular part  of the  symmetric matrix  and the
            strictly upper triangular part of C is not refer-
            enced.  On exit, the lower triangular part of the
            array  C is overwritten by the lower triangular part
            of the updated matrix.

     LDC    - INTEGER.

            On entry, LDC specifies the first dimension of C as
```

```
declared in  the  calling  (sub)  program.   LDC
must  be  at  least max( 1, n ).  Unchanged on exit.
```

 NAME
      ZTRMM - perform one of the matrix-matrix operations   B :=
      alpha*op( A )*B, or B := alpha*B*op( A )  where alpha is a
      scalar, B is an m by n matrix, A is a unit, or non-unit,
      upper or lower triangular matrix and op( A ) is one of   op(
      A ) = A or op( A ) = A' or op( A ) = conjg( A' )

 SYNOPSIS
      SUBROUTINE ZTRMM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                         LDA, B, LDB )

          CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

          INTEGER      M, N, LDA, LDB

          COMPLEX*16   ALPHA

          COMPLEX*16   A( LDA, * ), B( LDB, * )

 PURPOSE
      ZTRMM  performs one of the matrix-matrix operations

 PARAMETERS
      SIDE   - CHARACTER*1.
             On entry,  SIDE specifies whether  op( A ) multiplies
             B from the left or right as follows:

             SIDE = 'L' or 'l'   B := alpha*op( A )*B.

             SIDE = 'R' or 'r'   B := alpha*B*op( A ).

             Unchanged on exit.

      UPLO   - CHARACTER*1.
```

```
        On entry, UPLO specifies whether the matrix A is an
        upper or lower triangular matrix as follows:

        UPLO = 'U' or 'u'   A is an upper triangular matrix.

        UPLO = 'L' or 'l'   A is a lower triangular matrix.

        Unchanged on exit.

        TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
        form of op( A ) to be used in the matrix multiplica-
        tion as follows:

        TRANSA = 'N' or 'n'   op( A ) = A.

        TRANSA = 'T' or 't'   op( A ) = A'.

        TRANSA = 'C' or 'c'   op( A ) = conjg( A' ).

        Unchanged on exit.

DIAG    - CHARACTER*1.
        On entry, DIAG specifies whether or not A is unit
        triangular as follows:

        DIAG = 'U' or 'u'   A is assumed to be unit triangu-
        lar.

        DIAG = 'N' or 'n'   A is not assumed to be unit tri-
        angular.

        Unchanged on exit.

M       - INTEGER.
        On entry, M specifies the number of rows of B. M must
        be at least zero.  Unchanged on exit.

N       - INTEGER.
        On entry, N specifies the number of columns of B.  N
        must be at least zero.  Unchanged on exit.

ALPHA   - COMPLEX*16      .
        On entry,  ALPHA specifies the scalar  alpha. When
        alpha is zero then  A is not referenced and  B need
        not be set before entry.  Unchanged on exit.

A       -
         COMPLEX*16       array of DIMENSION ( LDA, k ), where k
        is m when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
        or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
```

```
            leading  k by k upper triangular part of the array  A
            must contain the upper triangular matrix  and the
            strictly lower triangular part of A is not refer-
            enced.  Before entry  with  UPLO = 'L' or 'l',  the
            leading  k by k lower triangular part of the array  A
            must contain the lower triangular matrix  and the
            strictly upper triangular part of A is not refer-
            enced.  Note that when  DIAG = 'U' or 'u',  the diag-
            onal elements of A  are not referenced either,  but
            are assumed to be  unity.  Unchanged on exit.

      LDA   - INTEGER.
            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program.  When  SIDE =
            'L' or 'l'  then LDA  must be at least  max( 1, m ),
            when  SIDE = 'R' or 'r' then LDA must be at least
            max( 1, n ).  Unchanged on exit.

      B     - COMPLEX*16       array of DIMENSION ( LDB, n ).
            Before entry,  the leading  m by n part of the array
            B must contain the matrix  B,  and  on exit  is
            overwritten  by the transformed matrix.

      LDB   - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   LDB
            must  be  at  least max( 1, m ).  Unchanged on exit.

NAME
     ZTRSM - solve one of the matrix equations   op( A )*X =
     alpha*B, or X*op( A ) = alpha*B,

SYNOPSIS
     SUBROUTINE ZTRSM ( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A,
                        LDA, B, LDB )

         CHARACTER*1  SIDE, UPLO, TRANSA, DIAG

         INTEGER      M, N, LDA, LDB

         COMPLEX*16   ALPHA

         COMPLEX*16   A( LDA, * ), B( LDB, * )

PURPOSE
     ZTRSM  solves one of the matrix equations

     where alpha is a scalar, X and B are m by n matrices, A is a
     unit, or non-unit,  upper or lower triangular matrix  and
     op( A )  is one  of

        op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg(
     A' ).

     The matrix X is overwritten on B.

PARAMETERS
     SIDE   - CHARACTER*1.
            On entry, SIDE specifies whether op( A ) appears on
            the left or right of X as follows:

            SIDE = 'L' or 'l'   op( A )*X = alpha*B.

            SIDE = 'R' or 'r'   X*op( A ) = alpha*B.

            Unchanged on exit.

     UPLO   - CHARACTER*1.
            On entry, UPLO specifies whether the matrix A is an
            upper or lower triangular matrix as follows:

            UPLO = 'U' or 'u'   A is an upper triangular matrix.

            UPLO = 'L' or 'l'   A is a lower triangular matrix.

            Unchanged on exit.

            TRANSA - CHARACTER*1.  On entry, TRANSA specifies the
```

```
            form of op( A ) to be used in the matrix

            multiplication as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = conjg( A' ).

            Unchanged on exit.

      DIAG   - CHARACTER*1.
            On entry, DIAG specifies whether or not A is unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be unit triangu-
            lar.

            DIAG = 'N' or 'n'   A is not assumed to be unit tri-
            angular.

            Unchanged on exit.

      M      - INTEGER.
            On entry, M specifies the number of rows of B. M must
            be at least zero.  Unchanged on exit.

      N      - INTEGER.
            On entry, N specifies the number of columns of B.  N
            must be at least zero.  Unchanged on exit.

      ALPHA  - COMPLEX*16      .
            On entry,  ALPHA specifies the scalar  alpha. When
            alpha is zero then  A is not referenced and  B need
            not be set before entry.  Unchanged on exit.

is m
      A      -
             COMPLEX*16       array of DIMENSION ( LDA, k ), where k
            when  SIDE = 'L' or 'l'  and is  n  when  SIDE = 'R'
            or 'r'.  Before entry  with  UPLO = 'U' or 'u',  the
            leading  k by k upper triangular part of the array  A
            must contain the upper triangular matrix  and the
            strictly lower triangular part of A is not refer-
            enced.  Before entry  with  UPLO = 'L' or 'l',  the
            leading  k by k lower triangular part of the array  A
            must contain the lower triangular matrix  and the
            strictly upper triangular part of A is not refer-
            enced.  Note that when  DIAG = 'U' or 'u',  the diag-
```

```
            onal elements of A  are not referenced either,  but
            are assumed to be  unity.  Unchanged on exit.

      LDA    - INTEGER.

            On entry, LDA specifies the first dimension of A as
            declared in the calling (sub) program.  When  SIDE =
            'L' or 'l'  then LDA  must be at least  max( 1, m ),
            when  SIDE = 'R' or 'r' then LDA must be at least
            max( 1, n ).  Unchanged on exit.

      B      - COMPLEX*16       array of DIMENSION ( LDB, n ).
            Before entry,  the leading  m by n part of the array
            B must contain  the  right-hand  side  matrix  B,
            and  on exit  is overwritten by the solution matrix
            X.

      LDB    - INTEGER.
            On entry, LDB specifies the first dimension of B as
            declared in  the  calling  (sub)  program.   LDB
            must  be  at  least max( 1, m ).  Unchanged on exit.

Chapter 18

LAPACK Concepts

18.1 Tridiagonal matrices [High86]

Tridiagonal matrices

$$A = \begin{bmatrix} a_1 & c_1 & & & 0 \\ b_2 & a_2 & c_2 & & \\ & b_3 & a_3 & \ddots & \\ & & \ddots & & c_{n-1} \\ 0 & & & b_n & a_n \end{bmatrix} \in \mathbb{R}^{n \times n}$$

arise in many areas of numerical analysis, such as spline analysis, difference methods for boundary value problems, and the numerical solution of linear second order recurrence relations. Since the nonzero elements of A occur only within a band of width three, the cost of solving a tridiagonal system $Ax = b$ using Gaussian elimination with partial pivoting is $O(n)$ flops, as opposed to the $O(n^3)$ flops required required when A is a full matrix.

18.2 Condition Number [High86]

Let A be a square nonsingular matrix and $||\cdot||$ a matrix norm. When computing solutions of linear systems $Ax = b$ one would usually like to know the condition number of A,

$$\text{cond } (A) = ||A|| \; ||A^{-1}||$$

, or at least an estimate, since this quantity measures the sensitivity of the true solution to perturbations in the data A and b, and features in various bounds for the norm of the error in the computed solution. For the I_∞ matrix norm, given for $A = (a_{ij})$ by

$$||A||_\infty = max_i \Sigma_j |a_{ij}|$$

or the l_1 matrix norm, $||A||_1 = ||A^T||_\infty ||A||$ is readily obtained whereas computation of $||A^{-1}||$ is more difficult.

18.3 Euclidean Norm [Ahre15]

The Euclidean norm of a vector $\overrightarrow{x}$ (sometimes referred to as $||\overrightarrow{x}||$) is defined as

$$||\overrightarrow{x}|| = \sqrt{\sum_{j=0}^{n-1} x_j^2}, \qquad x_j \in \mathbb{F}$$

Since the summands in the summation are all non-negative, there is no cancellation, so the Euclidean norm operation is usually of high accuracy. It can be implemented simply using a dot product operation on two copies of the same input vector, or by using the sum operation on the squares of the input vector. However, both of these methods are prone to unnecessary overflow and underflow. On one hand, if some input values were too big ($\geq \sqrt{2^{e_{max}+1}}$), the partial sum would overflow. The computed result would be `Inf` when the real Euclidean norm would be much smaller than the overflow threshold. On the other hand, if all input values were too small ($< \sqrt{2^{e_{min}}}$), their squared value would be smaller than the smallest representable floating point number and underflow would occur, causing the returned result to be 0. Scaling techniques can be used to handle the underflow/overflow issues. For example, the function **xnrm2** from the BLAS library scales input data by the intermediate maximum absolute value to avoid both overflow and underflow.

Chapter 19

LAPACK Overview

From the LAPACK User's Guide [LAPA99]:

We use the standard notation for a system of simultaneous linear equations:

$$AX = b$$

where A is the **coefficient matrix**, b is the **right hand side**, and x is the **solution**. A is assumed to be a square matrix of order n, but some of the individual routines allow A to be rectangular. If there are several right hand sides, we write

$$AX = B$$

where the columns of B are the individual right hand sides, and the columns of X are the corresponding solutions. The basic task is to compute X, given A and B.

If A is upper or lower triangular, this can be solved by a straighforward process of backward or forward substitution. Otherwise, the solution is obtained after first factorizing A as a product of triangular matrices (and possibly also a diagonal matrix or permutation matrix).

The form of the factorization depends on the properties of the matrix A. LAPACK provides routines for the following types of matrices, based on the stated factorizations:

- **general** matrices (LU factorization with partial pivoting):

  $$A = PLU$$

  where P is the permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

- **general band** matrices including **tridiagonal** matrices (LU factorization with partial pivoting): If A is m-by-n with kl subdiagonals and ku superdiagonals, the factorization is

  $$A = LU$$

  where L is a product of permutations and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl + ku$ superdiagonals.

- **symmetric and Hermitian positive definite** matrices including **band** matrices (Cholesky factorization):

$$A = U^T U \text{ or } A = LL^T \text{ in the symmetric case}$$

$$A = U^H U \text{ or } A = LL^H \text{ in the Hermitian case}$$

  where U is the upper triangular matrix and L is the lower triangular.

- **symmetric and Hermitian positive definite tridiagonal** matrices (LDL^T factorization):

$$A = UDU^T \text{ or } A = LDL^T \text{ in the symmetric case}$$

$$A = UDU^H \text{ or } A = LDL^H \text{ in the Hermitian case}$$

  where U is a unit upper bidiagonal matrix, L is unit lower bidiagonal, and D is diagonal.

- **symmetric and Hermitian indefinite** matrices (symmetric indefinite factorization):

$$A = UDU^T \text{ or } A = LDL^T \text{ in the symmetric case}$$

$$A = UDU^H \text{ or } A = LDL^H \text{ in the Hermitian case}$$

  where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with diagonal blocks of order 1 or 2.

The factorization for a general tridiagonal matrix is like that for a general band matrix with $kl = 1$ and $ku = 1$. The factorization for a symmetric positive definite band matrix with k superdiagonals (or subdiagonals) has the same form as for a symmetric positive definite matrix, but the factor U (or L) is a band matrix with k superdiagonals (subdiagonals). Band matrices use a compact band storage scheme describe in the LAPACK User's Guide [LAPA99] section 5.3.3. LAPACK routines are also provided for symmetric matrices (whether positive definite or indefinite) using **packed** storage, as described in the LAPACK User's Guide section 5.3.2.

While the primary use of a matrix factorization is to solve a system of equations, other related tasks are provided as well. Whereever possible, LAPACK provides routines to perform each of these tasks for each type of matrix and storage scheme. The following list relates the tasks to the last 3 characters of the name of the corresponding computational routine:

- **xyyTRF** factorize (obviously not needed for triangular matrices)
- **xyyTRS** use the factorization (or the matrix A itself if it is triangular) to solve by forward or backward substitution.
- **xyyCON** estimate the reciprocal of the condition number

$$\kappa(A) = ||A|| \cdot ||A^{-1}||$$

  Highman's modification and Hagar's method is used to estimate $|A^{-1}|$ except for symmetric positive definite tridiagonal matrices for which it is computed directly with comparable efficiency

- **xyyRFS** compute bounds on the error in the computed solution (returned by the xyyTRS routine), and refine the solution to reduce the backward error.
- **xyyTRI** use the factorization (or the matrix A itself if it is triangular) to compute A^{-1} (not provided for band matrices, because the inverse does not in general perserve bandedness)
- **xyyEQU** compute scaling factors to equilibrate A (not provided for tridiagonal, symmetric indefinite, or triangular matrices). These routines do not actually scale the matrices: auxiliary routines xLAQyy may be used for that purpose – see the code of the driver routines xyySVX for sample usage

Note that some of the above routines depend on the output of others:

- **xyyTRF** may work on any equilibrated matrix produced by xyyEQU and xLAQyy, if yy is one of {GE, GB, PO, PP, PB}.
- **xyyTRS** requires the factorization returned by xyyTRF.
- **xyyCON** requires the norm of the original matrix A, and the factorization returned by xyyTRF
- **xyyRFS** requires the original matrices A and B, the factorization returned by xyyTRF, and the solution X returned by xyyTRS
- **xyyTRI** requires the factorization returned by xyyTRF

The RFS ("refine solution") routines perform iterative refinement and compute backward and forward error bounds for the solution. Iterative refinement is done in the same precision as the input data. In particular, the residual is *not* computed with extra precision, as has been traditionally done. The benefit of this procedure is discussed in the LAPACK User's Guide section 4.4

19.1 General Matrix

operation	**Single precision**		**Double precision**	
	real	**complex**	**real**	**complex**
factorize	sgetrf	cgetrf	dgetrf	zgetrf
solve using factorization	sgetrs	cgetrs	dgetrs	zgetrs

SYNOPSIS
   Functions/Subroutines
       subroutine dgels (TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
            DGELS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine dgels (character TRANS, integer M, integer N, integer NRHS,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( * )
       WORK, integer LWORK, integer INFO)
        DGELS solves overdetermined or underdetermined systems for GE matrices

Purpose:
   DGELS solves overdetermined or underdetermined real linear systems
   involving an M-by-N matrix A, or its transpose, using a QR or LQ
   factorization of A.  It is assumed that A has full rank.

   The following options are provided:

   1. If TRANS = 'N' and m >= n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
      minimize || B - A*X ||.

   2. If TRANS = 'N' and m < n:  find the minimum norm solution of
      an underdetermined system A * X = B.

   3. If TRANS = 'T' and m >= n:  find the minimum norm solution of
      an undetermined system A**T * X = B.

   4. If TRANS = 'T' and m < n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
      minimize || B - A**T * X ||.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution
   matrix X.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N': the linear system involves A;
   = 'T': the linear system involves A**T.
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of
  columns of the matrices B and X. NRHS >=0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if M >= N, A is overwritten by details of its QR
             factorization as returned by DGEQRF;
  if M <  N, A is overwritten by details of its LQ
             factorization as returned by DGELQF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the matrix B of right hand side vectors, stored
  columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS
  if TRANS = 'T'.
  On exit, if INFO = 0, B is overwritten by the solution
  vectors, stored columnwise:
  if TRANS = 'N' and m >= n, rows 1 to n of B contain the least
  squares solution vectors; the residual sum of squares for the
  solution in each column is given by the sum of squares of
  elements N+1 to M in that column;
  if TRANS = 'N' and m < n, rows 1 to N of B contain the
  minimum norm solution vectors;
  if TRANS = 'T' and m >= n, rows 1 to M of B contain the
  minimum norm solution vectors;
  if TRANS = 'T' and m < n, rows 1 to M of B contain the
  least squares solution vectors; the residual sum of squares
  for the solution in each column is given by the sum of
  squares of elements M+1 to N in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= MAX(1,M,N).
```

```
 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.
   LWORK >= max( 1, MN + max( MN, NRHS ) ).
   For optimal performance,
   LWORK >= max( 1, MN + max( MN, NRHS )*NB ).
   where MN = min(M,N) and NB is the optimum block size.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO =  i, the i-th diagonal element of the
         triangular factor of A is zero, so that A does not have
         full rank; the least squares solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgelsd (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, IWORK, INFO)
            DGELSD computes the minimum-norm solution to a linear least
           squares problem for GE matrices

Function/Subroutine Documentation
   subroutine dgelsd (integer M, integer N, integer NRHS, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( ldb, *
       ) B, integer LDB, double precision, dimension( * ) S, double precision
       RCOND, integer RANK, double precision, dimension( * ) WORK, integer
       LWORK, integer, dimension( * ) IWORK, integer INFO)
        DGELSD computes the minimum-norm solution to a linear least squares
       problem for GE matrices

Purpose:
   DGELSD computes the minimum-norm solution to a real linear least
   squares problem:
      minimize 2-norm(| b - A*x |)
   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The problem is solved in three steps:
   (1) Reduce the coefficient matrix A to bidiagonal form with
       Householder transformations, reducing the original problem
       into a "bidiagonal least squares problem" (BLS)
   (2) Solve the BLS using a divide and conquer approach.
   (3) Apply back all the Householder tranformations to solve
       the original least squares problem.
```

```
  The effective rank of A is determined by treating as zero those
  singular values which are less than RCOND times the largest singular
  value.

  The divide and conquer algorithm makes very mild assumptions about
  floating point arithmetic. It will work on machines with a guard
  digit in add/subtract, or on those binary machines without guard
  digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
  Cray-2. It could conceivably fail on hexadecimal or decimal machines
  without guard digits, but we know of none.

Parameters:

 M
   M is INTEGER
   The number of rows of A. M >= 0.

 N
   N is INTEGER
   The number of columns of A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, A has been destroyed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, B is overwritten by the N-by-NRHS solution
   matrix X.  If m >= n and RANK = n, the residual
   sum-of-squares for the solution in the i-th column is given
   by the sum of squares of elements n+1:m in that column.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,max(M,N)).

 S
   S is DOUBLE PRECISION array, dimension (min(M,N))
```

```
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is DOUBLE PRECISION
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK must be at least 1.
  The exact minimum amount of workspace needed depends on M,
  N and NRHS. As long as LWORK is at least
  12*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS + (SMLSIZ+1)**2,
  if M is greater than or equal to N or
  12*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS + (SMLSIZ+1)**2,
  if M is less than N, the code will execute correctly.
  SMLSIZ is returned by ILAENV and is equal to the maximum
  size of the subproblems at the bottom of the computation
  tree (usually about 25), and
  NLVL = MAX( 0, INT( LOG_2( MIN( M,N )/(SMLSIZ+1) ) ) + 1 )
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  LIWORK >= max(1, 3 * MINMN * NLVL + 11 * MINMN),
  where MINMN = MIN( M,N ).
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
```

```
bidiagonal form did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgelss (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, INFO)
            DGELSS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine dgelss (integer M, integer N, integer NRHS, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( ldb, *
       ) B, integer LDB, double precision, dimension( * ) S, double precision
       RCOND, integer RANK, double precision, dimension( * ) WORK, integer
```

```
      LWORK, integer INFO)
       DGELSS solves overdetermined or underdetermined systems for GE
      matrices

Purpose:
   DGELSS computes the minimum norm solution to a real linear least
   squares problem:

   Minimize 2-norm(| b - A*x |).

   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The effective rank of A is determined by treating as zero those
   singular values which are less than RCOND times the largest singular value.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the first min(m,n) rows of A are overwritten with
   its right singular vectors, stored rowwise.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, B is overwritten by the N-by-NRHS solution
   matrix X.  If m >= n and RANK = n, the residual
```

```
  sum-of-squares for the solution in the i-th column is given
  by the sum of squares of elements n+1:m in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,max(M,N)).

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is DOUBLE PRECISION
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 1, and also:
  LWORK >= 3*min(M,N) + max( 2*min(M,N), max(M,N), NRHS )
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
        bidiagonal form did not converge to zero.

SYNOPSIS
   Functions/Subroutines
       subroutine dgelsy (M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK,
           LWORK, INFO)
            DGELSY solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine dgelsy (integer M, integer N, integer NRHS, double precision,

       DGELSY solves overdetermined or underdetermined systems for GE
      matrices

Purpose:
   DGELSY computes the minimum-norm solution to a real linear least
   squares problem:
   minimize || A * X - B ||
   using a complete orthogonal factorization of A.  A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution
   matrix X.

   The routine first computes a QR factorization with column pivoting:
               A * P = Q * [ R11 R12 ]
                           [  0  R22 ]
   with R11 defined as the largest leading submatrix whose estimated
   condition number is less than 1/RCOND.  The order of R11, RANK,
   is the effective rank of A.

   Then, R22 is considered to be negligible, and R12 is annihilated
   by orthogonal transformations from the right, arriving at the
   complete orthogonal factorization:
             A * P = Q * [ T11 0 ] * Z
                         [  0  0 ]
   The minimum-norm solution is then
             X = P * Z**T [ inv(T11)*Q1**T*B ]
                          [        0         ]
   where Q1 consists of the first RANK columns of Q.

   This routine is basically identical to the original xGELSX except
   three differences:
   o The call to the subroutine xGEQPF has been substituted by the
      the call to the subroutine xGEQP3. This subroutine is a Blas-3
      version of the QR factorization with column pivoting.
   o Matrix B (the right hand side) is updated with Blas-3.
   o The permutation of matrix B (the right hand side) is faster and
      more simple.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of
  columns of matrices B and X. NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, A has been overwritten by details of its
  complete orthogonal factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the M-by-NRHS right hand side matrix B.
  On exit, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,M,N).

JPVT
  JPVT is INTEGER array, dimension (N)
  On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted
  to the front of AP, otherwise column i is a free column.
  On exit, if JPVT(i) = k, then the i-th column of AP
  was the k-th column of A.

RCOND
  RCOND is DOUBLE PRECISION
  RCOND is used to determine the effective rank of A, which
  is defined as the order of the largest leading triangular
  submatrix R11 in the QR factorization with pivoting of A,
  whose estimated condition number < 1/RCOND.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the order of the submatrix
  R11.  This is the same as the order of the submatrix T11
  in the complete orthogonal factorization of A.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
```

```
  LWORK is INTEGER
  The dimension of the array WORK.
  The unblocked strategy requires that:
     LWORK >= MAX( MN+3*N+1, 2*MN+NRHS ),
  where MN = min( M, N ).
  The block algorithm requires that:
  LWORK >= MAX( MN+2*N+NB*(N+1), 2*MN+NB*NRHS ),
  where NB is an upper bound on the blocksize returned
  by ILAENV for the routines DGEQP3, DTZRZF, STZRQF, DORMQR,
  and DORMRZ.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: If INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgesv (N, NRHS, A, LDA, IPIV, B, LDB, INFO)
            DGESV computes the solution to system of linear equations A * X =
           B for GE matrices

Function/Subroutine Documentation
   subroutine dgesv (integer N, integer NRHS, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double
       precision, dimension( ldb, * ) B, integer LDB, integer INFO)
        DGESV computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:
   DGESV computes the solution to a real system of linear equations
               A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as
               A = P * L * U,
   where P is a permutation matrix, L is unit lower triangular, and U is
   upper triangular.  The factored form of A is then used to solve the
   system of equations A * X = B.
```

```
Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N coefficient matrix A.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices that define the permutation matrix P;
   row i of the matrix was interchanged with row IPIV(i).

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the N-by-NRHS matrix of right hand side matrix B.
   On exit, if INFO = 0, the N-by-NRHS solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
         has been completed, but the factor U is exactly
         singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgesvx (FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED,
           R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
            DGESVX computes the solution to system of linear equations A * X =
           B for GE matrices

Function/Subroutine Documentation
   subroutine dgesvx (character FACT, character TRANS, integer N, integer
       NRHS, double precision, dimension( lda, * ) A, integer LDA, double
       precision, dimension( ldaf, * ) AF, integer LDAF, integer, dimension( *
       ) IPIV, character EQUED, double precision, dimension( * ) R, double
       precision, dimension( * ) C, double precision, dimension( ldb, * ) B,
       integer LDB, double precision, dimension( ldx, * ) X, integer LDX,
       double precision RCOND, double precision, dimension( * ) FERR, double
       precision, dimension( * ) BERR, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
        DGESVX computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:
   DGESVX uses the LU factorization to compute the solution to a real
   system of linear equations
               A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
```

```
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
                 A = P * L * U,
      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Transpose)

 N
```

```
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by DGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF

  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by DGETRF; row i of the matrix was interchanged
```

```
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
  overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

```
X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)
  On exit, WORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If WORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  WORK(1) contains the reciprocal pivot growth factor for the
  leading INFO columns of A.
```

```
 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, and i is
     <= N:  U(i,i) is exactly zero.  The factorization has
            been completed, but the factor U is exactly
            singular, so the solution and error bounds
            could not be computed. RCOND = 0 is returned.
     = N+1: U is nonsingular, but RCOND is less than machine
            precision, meaning that the matrix is singular
            to working precision.  Nevertheless, the
            solution and error bounds are computed because
            there are a number of situations where the
            computed solution can be more accurate than the
            value of RCOND would suggest.
```

                                              (array double-float (*))
                                              (fortran-to-lisp::integer4)
                                              (array fortran-to-lisp::integer4
                                               (*))
                                              (string) (array double-float (*))
                                              (array double-float (*))
                                              (array double-float (*))
                                              (fortran-to-lisp::integer4)
                                              (array double-float (*))
                                              (fortran-to-lisp::integer4)
                                              (double-float)
                                              (array double-float (*))
                                              (array double-float (*))
                                              (array double-float (*))
                                              (array fortran-to-lisp::integer4
                                               (*))
                                              (fortran-to-lisp::integer4))
                                            :return-values
                                            '(fortran-to-lisp::fact

        DGESVXX computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:
   DGESVXX uses the LU factorization to compute the solution to a
   double precision system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   DGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DGESVXX would itself produce.

Description:
   The following steps are performed:
```

```
   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as
                 A = P * L * U,
      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND). If the reciprocal of the condition number is less
      than machine precision, the routine still goes on to solve for X
      and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
```

```
          equilibrated with scaling factors given by R and C.
          A, AF, and IPIV are not modified.
  = 'N':  The matrix A will be copied to AF and factored.
  = 'E':  The matrix A will be equilibrated if necessary, then
          copied to AF and factored.

TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by DGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
```

```
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by DGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
```

```
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
  Reciprocal pivot growth.  On exit, this contains the reciprocal
```

```
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In DGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
                      max_j (abs(XTRUE(j,i) - X(j,i)))
                     ------------------------------
                            max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * dlamch('Epsilon'). This error bound should only
```

```
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * dlamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*A, where S scales each row by a power of the
           radix so all absolute row sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                             abs(XTRUE(j,i) - X(j,i))
                      max_j ----------------------
                                   abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
           reciprocal condition number is less than the threshold
           sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
           almost certainly within a factor of 10 of the true error
           so long as the next entry is greater than the threshold
           sqrt(n) * dlamch('Epsilon'). This error bound should only
           be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * dlamch('Epsilon') to determine if the error
```

```
          estimate is "guaranteed". These reciprocal condition
          numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
          appropriately scaled matrix Z.
          Let Z = S*(A*diag(x)), where x is the solution for the
          current right-hand side and S scales each row of
          A*diag(x) by a power of the radix so all absolute row
          sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension (NPARAMS)
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)
```

```
 INFO
   INFO is INTEGER
   = 0:  Successful exit. The solution to every right-hand side is guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
       has been completed, but the factor U is exactly singular, so
       the solution and error bounds could not be computed. RCOND = 0
       is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
       not guaranteed. The solutions corresponding to other right-
       hand sides K with K > J may not be guaranteed as well, but
       only the first such right-hand side is reported. If a small
       componentwise error is not requested (PARAMS(3) = 0.0) then
       the Jth right-hand side is the first with a normwise error
       bound that is not guaranteed (the smallest J such
       that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
       the Jth right-hand side is the first with either a normwise or
       componentwise error bound that is not guaranteed (the smallest
       J such that either ERR_BNDS_NORM(J,1) = 0.0 or
       ERR_BNDS_COMP(J,1) = 0.0). See the definition of
       ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
       about all of the right-hand sides check ERR_BNDS_NORM or
       ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine dsgesv (N, NRHS, A, LDA, IPIV, B, LDB, X, LDX, WORK, SWORK,
           ITER, INFO)
            DSGESV computes the solution to system of linear equations A * X =
           B for GE matrices (mixed precision with iterative refinement)

Function/Subroutine Documentation
   subroutine dsgesv (integer N, integer NRHS, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double
       precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( ldx, * ) X, integer LDX, double precision, dimension( n, * )
       WORK, real, dimension( * ) SWORK, integer ITER, integer INFO)
        DSGESV computes the solution to system of linear equations A * X = B
       for GE matrices (mixed precision with iterative refinement)

 Purpose:
   DSGESV computes the solution to a real system of linear equations
               A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   DSGESV first attempts to factorize the matrix in SINGLE PRECISION
   and use this factorization within an iterative refinement procedure
   to produce a solution with DOUBLE PRECISION normwise backward error
   quality (see below). If the approach fails the method switches to a
   DOUBLE PRECISION factorization and solve.

   The iterative refinement is not going to be a winning strategy if
```

```
   the ratio SINGLE PRECISION performance over DOUBLE PRECISION
   performance is too small. A reasonable strategy should take the
   number of right-hand sides and the size of the matrix into account.
   This might be done with a call to ILAENV in the future. Up to now, we
   always try iterative refinement.

   The iterative refinement process is stopped if
                ITER > ITERMAX
   or for all the RHS we have:
                RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
   where
   o ITER is the number of the current iteration in the iterative
     refinement process
   o RNRM is the infinity-norm of the residual
   o XNRM is the infinity-norm of the solution
   o ANRM is the infinity-operator-norm of the matrix A
   o EPS is the machine epsilon returned by DLAMCH('Epsilon')
   The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array,
   dimension (LDA,N)
   On entry, the N-by-N coefficient matrix A.
   On exit, if iterative refinement has been successfully used
   (INFO.EQ.0 and ITER.GE.0, see description below), then A is
   unchanged, if double precision factorization has been used
   (INFO.EQ.0 and ITER.LT.0, see description below), then the
   array A contains the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices that define the permutation matrix P;
   row i of the matrix was interchanged with row IPIV(i).
```

```
  Corresponds either to the single precision factorization
  (if INFO.EQ.0 and ITER.GE.0) or the double precision
  factorization (if INFO.EQ.0 and ITER.LT.0).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (N,NRHS)
  This array is used to hold the residual vectors.

SWORK
  SWORK is REAL array, dimension (N*(N+NRHS))
  This array is used to use the single precision matrix and the
  right-hand sides or solutions in single precision.

ITER
  ITER is INTEGER
  < 0: iterative refinement has failed, double precision
       factorization has been performed
  -1 : the routine fell back to full precision for
       implementation- or machine-specific reasons
  -2 : narrowing the precision induced an overflow,
       the routine fell back to full precision
  -3 : failure of SGETRF
  -31: stop the iterative refinement after the 30th iterations
   > 0: iterative refinement has been sucessfully used.
        Returns the number of iterations

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) computed in DOUBLE PRECISION is
        exactly zero.  The factorization has been completed,
        but the factor U is exactly singular, so the solution
        could not be computed.

SYNOPSIS
   Functions/Subroutines
       subroutine sgels (TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
            SGELS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine sgels (character TRANS, integer M, integer N, integer NRHS,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( * ) WORK, integer LWORK, integer INFO)
        SGELS solves overdetermined or underdetermined systems for GE matrices

Purpose:
   SGELS solves overdetermined or underdetermined real linear systems
   involving an M-by-N matrix A, or its transpose, using a QR or LQ
   factorization of A.  It is assumed that A has full rank.

   The following options are provided:

   1. If TRANS = 'N' and m >= n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
            minimize || B - A*X ||.

   2. If TRANS = 'N' and m < n:  find the minimum norm solution of
      an underdetermined system A * X = B.

   3. If TRANS = 'T' and m >= n:  find the minimum norm solution of
      an undetermined system A**T * X = B.

   4. If TRANS = 'T' and m < n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
           minimize || B - A**T * X ||.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N': the linear system involves A;
   = 'T': the linear system involves A**T.

 M
```

```
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of
  columns of the matrices B and X. NRHS >=0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if M >= N, A is overwritten by details of its QR
     factorization as returned by SGEQRF;
  if M <  N, A is overwritten by details of its LQ
     factorization as returned by SGELQF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the matrix B of right hand side vectors, stored
  columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS
  if TRANS = 'T'.
  On exit, if INFO = 0, B is overwritten by the solution
  vectors, stored columnwise:
  if TRANS = 'N' and m >= n, rows 1 to n of B contain the least
  squares solution vectors; the residual sum of squares for the
  solution in each column is given by the sum of squares of
  elements N+1 to M in that column;
  if TRANS = 'N' and m < n, rows 1 to N of B contain the
  minimum norm solution vectors;
  if TRANS = 'T' and m >= n, rows 1 to M of B contain the
  minimum norm solution vectors;
  if TRANS = 'T' and m < n, rows 1 to M of B contain the
  least squares solution vectors; the residual sum of squares
  for the solution in each column is given by the sum of
  squares of elements M+1 to N in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= MAX(1,M,N).

WORK
```

```
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= max( 1, MN + max( MN, NRHS ) ).
  For optimal performance,
  LWORK >= max( 1, MN + max( MN, NRHS )*NB ).
  where MN = min(M,N) and NB is the optimum block size.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO =  i, the i-th diagonal element of the
        triangular factor of A is zero, so that A does not have
        full rank; the least squares solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgelsd (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, IWORK, INFO)
            SGELSD computes the minimum-norm solution to a linear least
           squares problem for GE matrices

Function/Subroutine Documentation
   subroutine sgelsd (integer M, integer N, integer NRHS, real, dimension(
       lda, * ) A, integer LDA, real, dimension( ldb, * ) B, integer LDB,
       real, dimension( * ) S, real RCOND, integer RANK, real, dimension( * )
       WORK, integer LWORK, integer, dimension( * ) IWORK, integer INFO)
        SGELSD computes the minimum-norm solution to a linear least squares
       problem for GE matrices

Purpose:
   SGELSD computes the minimum-norm solution to a real linear least
   squares problem:
                minimize 2-norm(| b - A*x |)
   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution
   matrix X.

   The problem is solved in three steps:
   (1) Reduce the coefficient matrix A to bidiagonal form with
       Householder transformations, reducing the original problem
       into a "bidiagonal least squares problem" (BLS)
   (2) Solve the BLS using a divide and conquer approach.
   (3) Apply back all the Householder tranformations to solve
       the original least squares problem.
```

```
  The effective rank of A is determined by treating as zero those
  singular values which are less than RCOND times the largest singular
  value.

  The divide and conquer algorithm makes very mild assumptions about
  floating point arithmetic. It will work on machines with a guard
  digit in add/subtract, or on those binary machines without guard
  digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
  Cray-2. It could conceivably fail on hexadecimal or decimal machines
  without guard digits, but we know of none.

Parameters:

 M
   M is INTEGER
   The number of rows of A. M >= 0.

 N
   N is INTEGER
   The number of columns of A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, A has been destroyed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, B is overwritten by the N-by-NRHS solution
   matrix X.  If m >= n and RANK = n, the residual
   sum-of-squares for the solution in the i-th column is given
   by the sum of squares of elements n+1:m in that column.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,max(M,N)).

 S
   S is REAL array, dimension (min(M,N))
```

```
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is REAL
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK must be at least 1.
  The exact minimum amount of workspace needed depends on M,
  N and NRHS. As long as LWORK is at least
  12*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS + (SMLSIZ+1)**2,
  if M is greater than or equal to N or
  12*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS + (SMLSIZ+1)**2,
  if M is less than N, the code will execute correctly.
  SMLSIZ is returned by ILAENV and is equal to the maximum
  size of the subproblems at the bottom of the computation
  tree (usually about 25), and
  NLVL = MAX( 0, INT( LOG_2( MIN( M,N )/(SMLSIZ+1) ) ) + 1 )
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the array WORK and the
  minimum size of the array IWORK, and returns these values as
  the first entries of the WORK and IWORK arrays, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  LIWORK >= max(1, 3*MINMN*NLVL + 11*MINMN),
  where MINMN = MIN( M,N ).
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
```

```
if INFO = i, i off-diagonal elements of an intermediate
bidiagonal form did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgelss (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, INFO)
            SGELSS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine sgelss (integer M, integer N, integer NRHS, real, dimension(
       lda, * ) A, integer LDA, real, dimension( ldb, * ) B, integer LDB,
       real, dimension( * ) S, real RCOND, integer RANK, real, dimension( * )
       WORK, integer LWORK, integer INFO)
        SGELSS solves overdetermined or underdetermined systems for GE
       matrices

Purpose:
   SGELSS computes the minimum norm solution to a real linear least
   squares problem:

   Minimize 2-norm(| b - A*x |).

   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The effective rank of A is determined by treating as zero those
   singular values which are less than RCOND times the largest singular
   value.
```

```
Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the first min(m,n) rows of A are overwritten with
   its right singular vectors, stored rowwise.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, B is overwritten by the N-by-NRHS solution
   matrix X.  If m >= n and RANK = n, the residual
   sum-of-squares for the solution in the i-th column is given
   by the sum of squares of elements n+1:m in that column.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,max(M,N)).

 S
   S is REAL array, dimension (min(M,N))
   The singular values of A in decreasing order.
   The condition number of A in the 2-norm = S(1)/S(min(m,n)).

 RCOND
   RCOND is REAL
   RCOND is used to determine the effective rank of A.
   Singular values S(i) <= RCOND*S(1) are treated as zero.
   If RCOND < 0, machine precision is used instead.

 RANK
```

```
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

 WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 1, and also:
  LWORK >= 3*min(M,N) + max( 2*min(M,N), max(M,N), NRHS )
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
        bidiagonal form did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgelsy (M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK,
           LWORK, INFO)
            SGELSY solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine sgelsy (integer M, integer N, integer NRHS, real, dimension(
       lda, * ) A, integer LDA, real, dimension( ldb, * ) B, integer LDB,
       integer, dimension( * ) JPVT, real RCOND, integer RANK, real,
       dimension( * ) WORK, integer LWORK, integer INFO)
        SGELSY solves overdetermined or underdetermined systems for GE
       matrices

Purpose:
   SGELSY computes the minimum-norm solution to a real linear least
   squares problem:
                minimize || A * X - B ||
   using a complete orthogonal factorization of A.  A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution
   matrix X.

   The routine first computes a QR factorization with column pivoting:
                A * P = Q * [ R11 R12 ]
                            [  0  R22 ]
   with R11 defined as the largest leading submatrix whose estimated
   condition number is less than 1/RCOND.  The order of R11, RANK,
   is the effective rank of A.

   Then, R22 is considered to be negligible, and R12 is annihilated
   by orthogonal transformations from the right, arriving at the
   complete orthogonal factorization:
               A * P = Q * [ T11 0 ] * Z
                           [  0  0 ]
   The minimum-norm solution is then
               X = P * Z**T [ inv(T11)*Q1**T*B ]
                            [        0         ]
```

```
  where Q1 consists of the first RANK columns of Q.

  This routine is basically identical to the original xGELSX except
  three differences:
  o The call to the subroutine xGEQPF has been substituted by the
    the call to the subroutine xGEQP3. This subroutine is a Blas-3
    version of the QR factorization with column pivoting.
  o Matrix B (the right hand side) is updated with Blas-3.
  o The permutation of matrix B (the right hand side) is faster and
    more simple.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of
   columns of matrices B and X. NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, A has been overwritten by details of its
   complete orthogonal factorization.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, the N-by-NRHS solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,M,N).

 JPVT
   JPVT is INTEGER array, dimension (N)
   On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted
   to the front of AP, otherwise column i is a free column.
   On exit, if JPVT(i) = k, then the i-th column of AP
```

```
  was the k-th column of A.

RCOND
  RCOND is REAL
  RCOND is used to determine the effective rank of A, which
  is defined as the order of the largest leading triangular
  submatrix R11 in the QR factorization with pivoting of A,
  whose estimated condition number < 1/RCOND.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the order of the submatrix
  R11.  This is the same as the order of the submatrix T11
  in the complete orthogonal factorization of A.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  The unblocked strategy requires that:
  LWORK >= MAX( MN+3*N+1, 2*MN+NRHS ),
  where MN = min( M, N ).
  The block algorithm requires that:
  LWORK >= MAX( MN+2*N+NB*(N+1), 2*MN+NB*NRHS ),
  where NB is an upper bound on the blocksize returned
  by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR,
  and SORMRZ.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: If INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine sgesv (N, NRHS, A, LDA, IPIV, B, LDB, INFO)
            SGESV computes the solution to system of linear equations A * X =
           B for GE matrices (simple driver)

Function/Subroutine Documentation
   subroutine sgesv (integer N, integer NRHS, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, real, dimension( ldb, * ) B,
       integer LDB, integer INFO)
        SGESV computes the solution to system of linear equations A * X = B
       for GE matrices (simple driver)

Purpose:
   SGESV computes the solution to a real system of linear equations
               A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as
               A = P * L * U,
   where P is a permutation matrix, L is unit lower triangular, and U is
   upper triangular.  The factored form of A is then used to solve the
   system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N coefficient matrix A.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices that define the permutation matrix P;
   row i of the matrix was interchanged with row IPIV(i).
```

```
B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS matrix of right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
        has been completed, but the factor U is exactly
        singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine sgesvx (FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED,
          R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
           SGESVX computes the solution to system of linear equations A * X =
          B for GE matrices

Function/Subroutine Documentation
   subroutine sgesvx (character FACT, character TRANS, integer N, integer
       NRHS, real, dimension( lda, * ) A, integer LDA, real, dimension( ldaf,
       * ) AF, integer LDAF, integer, dimension( * ) IPIV, character EQUED,
       real, dimension( * ) R, real, dimension( * ) C, real, dimension( ldb, *
       ) B, integer LDB, real, dimension( ldx, * ) X, integer LDX, real RCOND,
       real, dimension( * ) FERR, real, dimension( * ) BERR, real, dimension(
       * ) WORK, integer, dimension( * ) IWORK, integer INFO)
        SGESVX computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:
   SGESVX uses the LU factorization to compute the solution to a real
   system of linear equations
               A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
                  A = P * L * U,
      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.
```

```
   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
   not 'N', then A must have been equilibrated by the scaling
   factors in R and/or C.  A is not modified if FACT = 'F' or
   'N', or if FACT = 'E' and EQUED = 'N' on exit.

   On exit, if EQUED .ne. 'N', A is scaled as follows:
   EQUED = 'R':  A := diag(R) * A
```

```
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is REAL array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by SGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by SGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
```

```
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by
  diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
  overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
```

```
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (4*N)
  On exit, WORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If WORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  WORK(1) contains the reciprocal pivot growth factor for the
  leading INFO columns of A.

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
    <= N:  U(i,i) is exactly zero.  The factorization has
           been completed, but the factor U is exactly
           singular, so the solution and error bounds
           could not be computed. RCOND = 0 is returned.
    = N+1: U is nonsingular, but RCOND is less than machine
           precision, meaning that the matrix is singular
           to working precision.  Nevertheless, the
           solution and error bounds are computed because
           there are a number of situations where the
```

```
computed solution can be more accurate than the
value of RCOND would suggest.
```

      ERR_BNDS_COMP, integer NPARAMS, real, dimension( * ) PARAMS, real,
      dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SGESVXX computes the solution to system of linear equations A * X = B
      for GE matrices

Purpose:
   SGESVXX uses the LU factorization to compute the solution to a
   real system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SGESVXX would itself produce.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as

                 A = P * L * U,

      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
```

```
      is used to estimate the condition number of the matrix A (see
      argument RCOND). If the reciprocal of the condition number is less
      than machine precision, the routine still goes on to solve for X
      and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
```

```
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is REAL array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by SGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by SGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.
```

```
  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
```

```
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In SGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
```

```
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
                      max_j (abs(XTRUE(j,i) - X(j,i)))
                     ------------------------------
                           max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
          reciprocal condition number.  Compared with the threshold
          sqrt(n) * slamch('Epsilon') to determine if the error
          estimate is "guaranteed". These reciprocal condition
          numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
          appropriately scaled matrix Z.
          Let Z = S*A, where S scales each row by a power of the
          radix so all absolute row sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP

  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:
```

```
  Componentwise relative error in the ith solution vector:
                             abs(XTRUE(j,i) - X(j,i))
                      max_j ----------------------
                                   abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
           reciprocal condition number is less than the threshold
           sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*(A*diag(x)), where x is the solution for the
           current right-hand side and S scales each row of
           A*diag(x) by a power of the radix so all absolute row
           sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
```

```
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
        guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
    = N+J: The solution corresponding to the Jth right-hand side is
           not guaranteed. The solutions corresponding to other right-
           hand sides K with K > J may not be guaranteed as well, but
           only the first such right-hand side is reported. If a small
           componentwise error is not requested (PARAMS(3) = 0.0) then
           the Jth right-hand side is the first with a normwise error
           bound that is not guaranteed (the smallest J such
```

```
that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
the Jth right-hand side is the first with either a normwise or
componentwise error bound that is not guaranteed (the smallest
J such that either ERR_BNDS_NORM(J,1) = 0.0 or
ERR_BNDS_COMP(J,1) = 0.0). See the definition of
ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
about all of the right-hand sides check ERR_BNDS_NORM or
ERR_BNDS_COMP.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgels (TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
            CGELS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine cgels (character TRANS, integer M, integer N, integer NRHS,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( ldb, *
       ) B, integer LDB, complex, dimension( * ) WORK, integer LWORK, integer
       INFO)
        CGELS solves overdetermined or underdetermined systems for GE matrices

Purpose:
   CGELS solves overdetermined or underdetermined complex linear systems
   involving an M-by-N matrix A, or its conjugate-transpose, using a QR
   or LQ factorization of A.  It is assumed that A has full rank.

   The following options are provided:

   1. If TRANS = 'N' and m >= n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
      minimize || B - A*X ||.

   2. If TRANS = 'N' and m < n:  find the minimum norm solution of
      an underdetermined system A * X = B.

   3. If TRANS = 'C' and m >= n:  find the minimum norm solution of
      an undetermined system A**H * X = B.

   4. If TRANS = 'C' and m < n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
      minimize || B - A**H * X ||.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N': the linear system involves A;
   = 'C': the linear system involves A**H.
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of
  columns of the matrices B and X. NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  if M >= N, A is overwritten by details of its QR
    factorization as returned by CGEQRF;
  if M <  N, A is overwritten by details of its LQ
     factorization as returned by CGELQF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the matrix B of right hand side vectors, stored
  columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS
  if TRANS = 'C'.
  On exit, if INFO = 0, B is overwritten by the solution
  vectors, stored columnwise:
  if TRANS = 'N' and m >= n, rows 1 to n of B contain the least
  squares solution vectors; the residual sum of squares for the
  solution in each column is given by the sum of squares of the
  modulus of elements N+1 to M in that column;
  if TRANS = 'N' and m < n, rows 1 to N of B contain the
  minimum norm solution vectors;
  if TRANS = 'C' and m >= n, rows 1 to M of B contain the
  minimum norm solution vectors;
  if TRANS = 'C' and m < n, rows 1 to M of B contain the
  least squares solution vectors; the residual sum of squares
  for the solution in each column is given by the sum of
  squares of the modulus of elements M+1 to N in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= MAX(1,M,N).

WORK
```

```
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= max( 1, MN + max( MN, NRHS ) ).
  For optimal performance,
  LWORK >= max( 1, MN + max( MN, NRHS )*NB ).
  where MN = min(M,N) and NB is the optimum block size.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO =  i, the i-th diagonal element of the
     triangular factor of A is zero, so that A does not have
     full rank; the least squares solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgelsd (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, RWORK, IWORK, INFO)
            CGELSD computes the minimum-norm solution to a linear least
           squares problem for GE matrices

Function/Subroutine Documentation
   subroutine cgelsd (integer M, integer N, integer NRHS, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldb, * ) B, integer LDB,
       real, dimension( * ) S, real RCOND, integer RANK, complex, dimension( *
       ) WORK, integer LWORK, real, dimension( * ) RWORK, integer, dimension(
       * ) IWORK, integer INFO)
        CGELSD computes the minimum-norm solution to a linear least squares
       problem for GE matrices

Purpose:

   CGELSD computes the minimum-norm solution to a real linear least
   squares problem:
      minimize 2-norm(| b - A*x |)
   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The problem is solved in three steps:
   (1) Reduce the coefficient matrix A to bidiagonal form with
       Householder tranformations, reducing the original problem
```

```
      into a "bidiagonal least squares problem" (BLS)
  (2) Solve the BLS using a divide and conquer approach.
  (3) Apply back all the Householder tranformations to solve
      the original least squares problem.

  The effective rank of A is determined by treating as zero those
  singular values which are less than RCOND times the largest singular
  value.

  The divide and conquer algorithm makes very mild assumptions about
  floating point arithmetic. It will work on machines with a guard
  digit in add/subtract, or on those binary machines without guard
  digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
  Cray-2. It could conceivably fail on hexadecimal or decimal machines
  without guard digits, but we know of none.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, A has been destroyed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,M).

 B
   B is COMPLEX array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, B is overwritten by the N-by-NRHS solution matrix X.
   If m >= n and RANK = n, the residual sum-of-squares for
   the solution in the i-th column is given by the sum of
   squares of the modulus of elements n+1:m in that column.

 LDB
   LDB is INTEGER
```

```
  The leading dimension of the array B.  LDB >= max(1,M,N).

S
  S is REAL array, dimension (min(M,N))
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is REAL
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK must be at least 1.
  The exact minimum amount of workspace needed depends on M,
  N and NRHS. As long as LWORK is at least
     2 * N + N * NRHS
  if M is greater than or equal to N or
     2 * M + M * NRHS
  if M is less than N, the code will execute correctly.
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the array WORK and the
  minimum sizes of the arrays RWORK and IWORK, and returns
  these values as the first entries of the WORK, RWORK and
  IWORK arrays, and no error message related to LWORK is issued
  by XERBLA.

RWORK
  RWORK is REAL array, dimension (MAX(1,LRWORK))
  LRWORK >=
     10*N + 2*N*SMLSIZ + 8*N*NLVL + 3*SMLSIZ*NRHS +
     MAX( (SMLSIZ+1)**2, N*(1+NRHS) + 2*NRHS )
  if M is greater than or equal to N or
     10*M + 2*M*SMLSIZ + 8*M*NLVL + 3*SMLSIZ*NRHS +
     MAX( (SMLSIZ+1)**2, N*(1+NRHS) + 2*NRHS )
  if M is less than N, the code will execute correctly.
  SMLSIZ is returned by ILAENV and is equal to the maximum
```

```
  size of the subproblems at the bottom of the computation
  tree (usually about 25), and
     NLVL = MAX( 0, INT( LOG_2( MIN( M,N )/(SMLSIZ+1) ) ) + 1 )
  On exit, if INFO = 0, RWORK(1) returns the minimum LRWORK.

 IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  LIWORK >= max(1, 3*MINMN*NLVL + 11*MINMN),
  where MINMN = MIN( M,N ).
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
        bidiagonal form did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgelss (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, RWORK, INFO)
            CGELSS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine cgelss (integer M, integer N, integer NRHS, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldb, * ) B, integer LDB,
       real, dimension( * ) S, real RCOND, integer RANK, complex, dimension( *
       ) WORK, integer LWORK, real, dimension( * ) RWORK, integer INFO)
        CGELSS solves overdetermined or underdetermined systems for GE
       matrices

Purpose:

   CGELSS computes the minimum norm solution to a complex linear
   least squares problem:

   Minimize 2-norm(| b - A*x |).

   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The effective rank of A is determined by treating as zero those
   singular values which are less than RCOND times the largest singular value.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A. N >= 0.

 NRHS
   NRHS is INTEGER
```

```
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X. NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the first min(m,n) rows of A are overwritten with
  its right singular vectors, stored rowwise.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the M-by-NRHS right hand side matrix B.
  On exit, B is overwritten by the N-by-NRHS solution matrix X.
  If m >= n and RANK = n, the residual sum-of-squares for
  the solution in the i-th column is given by the sum of
  squares of the modulus of elements n+1:m in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,M,N).

S
  S is REAL array, dimension (min(M,N))
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is REAL
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 1, and also:
  LWORK >=  2*min(M,N) + max(M,N,NRHS)
  For good performance, LWORK should generally be larger.
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (5*min(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
        bidiagonal form did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgelsy (M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK,
           LWORK, RWORK, INFO)
            CGELSY solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine cgelsy (integer M, integer N, integer NRHS, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldb, * ) B, integer LDB,
       integer, dimension( * ) JPVT, real RCOND, integer RANK, complex,
       dimension( * ) WORK, integer LWORK, real, dimension( * ) RWORK, integer
       INFO)
        CGELSY solves overdetermined or underdetermined systems for GE
       matrices

Purpose:

   CGELSY computes the minimum-norm solution to a complex linear least
   squares problem:
      minimize || A * X - B ||
   using a complete orthogonal factorization of A.  A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The routine first computes a QR factorization with column pivoting:
      A * P = Q * [ R11 R12 ]
                  [  0  R22 ]
   with R11 defined as the largest leading submatrix whose estimated
   condition number is less than 1/RCOND.  The order of R11, RANK,
   is the effective rank of A.

   Then, R22 is considered to be negligible, and R12 is annihilated
   by unitary transformations from the right, arriving at the
```

```
   complete orthogonal factorization:
        A * P = Q * [ T11 0 ] * Z
                    [  0  0 ]
   The minimum-norm solution is then
        X = P * Z**H [ inv(T11)*Q1**H*B ]
                     [        0         ]
   where Q1 consists of the first RANK columns of Q.

   This routine is basically identical to the original xGELSX except
   three differences:
     o The permutation of matrix B (the right hand side) is faster and
       more simple.
     o The call to the subroutine xGEQPF has been substituted by the
       the call to the subroutine xGEQP3. This subroutine is a Blas-3
       version of the QR factorization with column pivoting.
     o Matrix B (the right hand side) is updated with Blas-3.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of
   columns of matrices B and X. NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, A has been overwritten by details of its
   complete orthogonal factorization.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is COMPLEX array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, the N-by-NRHS solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,M,N).
```

```
JPVT
  JPVT is INTEGER array, dimension (N)
  On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted
  to the front of AP, otherwise column i is a free column.
  On exit, if JPVT(i) = k, then the i-th column of A*P
  was the k-th column of A.

RCOND
  RCOND is REAL
  RCOND is used to determine the effective rank of A, which
  is defined as the order of the largest leading triangular
  submatrix R11 in the QR factorization with pivoting of A,
  whose estimated condition number < 1/RCOND.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the order of the submatrix
  R11.  This is the same as the order of the submatrix T11
  in the complete orthogonal factorization of A.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  The unblocked strategy requires that:
    LWORK >= MN + MAX( 2*MN, N+1, MN+NRHS )
  where MN = min(M,N).
  The block algorithm requires that:
    LWORK >= MN + MAX( 2*MN, NB*(N+1), MN+MN*NB, MN+NB*NRHS )
  where NB is an upper bound on the blocksize returned
  by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR,
  and CUNMRZ.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

SYNOPSIS
   Functions/Subroutines
       subroutine cgesv (N, NRHS, A, LDA, IPIV, B, LDB, INFO)
            CGESV computes the solution to system of linear equations A * X =
           B for GE matrices (simple driver)

Function/Subroutine Documentation
   subroutine cgesv (integer N, integer NRHS, complex, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, complex, dimension( ldb, * )
       B, integer LDB, integer INFO)
        CGESV computes the solution to system of linear equations A * X = B
       for GE matrices (simple driver)

Purpose:

   CGESV computes the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as
      A = P * L * U,
   where P is a permutation matrix, L is unit lower triangular, and U is
   upper triangular.  The factored form of A is then used to solve the
   system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N coefficient matrix A.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices that define the permutation matrix P;
  row i of the matrix was interchanged with row IPIV(i).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS matrix of right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
        has been completed, but the factor U is exactly
        singular, so the solution could not be computed.
```
