PermutationGroup examples

=====

PermutationGroup implements permutation groups acting on a set S, all subgroups of the symmetric group of S, represented as a list of permutations (generators). Note that therefore the objects are not members of the Axiom category Group.

Using the idea of base and strong generators by Sims, basic routines and algorithms are implemented so that the word problem for permutation groups can be solved.

```
x : PERM INT := [[1,3,5],[7,11,9]]
```

```
(1 3 5)(7 11 9)
```

```
y : PERM INT := [[3,5,7,9]]
```

```
(3 5 7 9)
```

```
z : PERM INT := [1,3,11]
```

```
(1 3 11)
```

```
g1 : PERMGRP INT := [ x , y ]
```

```
<(1 3 5)(7 11 9),(3 5 7 9)>
```

```
g2 : PERMGRP INT := [ x , z ]
```

```
<(1 3 5)(7 11 9),(1 3 11)>
```

```
g3 : PERMGRP INT := [ y , z ]
```

```
<(3 5 7 9),(1 3 11)>
```

```

domain HACKPI Pi

What is the purpose of the HACKPI domain?

HACKPI is a hack provided for the benefit of the axiom interpreter. As a mathematical type, it is the simple transcendental extension $\mathbb{Q}(\pi)$ of the rational numbers. This type allows interactive users to use the name '%pi' without a type both where a numerical value is expected [as in `draw(sin x,x=-%pi..%pi)`] or when the exact symbolic value is meant. The interpreter defaults a typeless %pi to HACKPI and then uses the various conversions to cast it further as required by the context.

One could argue that it is unfair to single %pi out from other constants, but it occurs frequently enough in school examples (specially for graphs) so it was worth a special hack. In a non-interactive environment (library), HACKPI would not exist.

(Manuel Bronstein)

— domain ACPLLOT PlaneAlgebraicCurvePlot —

```
)abbrev domain ACPLLOT PlaneAlgebraicCurvePlot
++ Author: Clifton J. Williamson and Timothy Daly
++ Date Created: Fall 1988
++ Date Last Updated: 27 April 1990
++ Description:
++ Plot a NON-SINGULAR plane algebraic curve  $p(x,y) = 0$ .
```

```
PlaneAlgebraicCurvePlot() : SIG == CODE where
```

```
SIG ==> PlottablePlaneCurveCategory with
```

```

makeSketch : (Polynomial Integer, Symbol, Symbol, Segment Fraction Integer,
              Segment Fraction Integer) -> %
  ++ makeSketch(p,x,y,a..b,c..d) creates an ACPLLOT of the
  ++ curve \spad{p = 0} in the region a <= x <= b, c <= y <= d.
  ++ More specifically, 'makeSketch' plots a non-singular algebraic curve
  ++ \spad{p = 0} in an rectangular region xMin <= x <= xMax,
  ++ yMin <= y <= yMax. The user inputs
  ++ \spad{makeSketch(p,x,y,xMin..xMax,yMin..yMax)}.
  ++ Here p is a polynomial in the variables x and y with
  ++ integer coefficients (p belongs to the domain
  ++ \spad{Polynomial Integer}). The case
  ++ where p is a polynomial in only one of the variables is
  ++ allowed. The variables x and y are input to specify the
  ++ the coordinate axes. The horizontal axis is the x-axis and
  ++ the vertical axis is the y-axis. The rational numbers
  ++ xMin,...,yMax specify the boundaries of the region in
  ++ which the curve is to be plotted.
  ++
  ++X makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACPLLOT

refine : (%, DoubleFloat) -> %
  ++ refine(p,x) is not documented
  ++
  ++X sketch:=makeSketch(x+y,x,y,-1/2..1/2,-1/2..1/2)$ACPLLOT
  ++X refined:=refine(sketch,0.1)

=====
Plot examples
=====

The Plot (PLOT) domain supports plotting of functions defined over a real number system. Plot is limited to 2 dimensional plots.

The function plot: (F -> F,R) -> % plots the function f(x) on the interval a..b. So we need to define a function that maps from DoubleFloat to DoubleFloat:

```
fp:=(t:DFLOAT):DFLOAT +-> sin(t)
```

and then feed it to the plot function with a Segment DoubleFloat

```
plot(fp,-1.0..1.0)$PLOT
```

```

)abbrev domain PLOT Plot
++ Author: Michael Monagan (revised by Clifton J. Williamson)
++ Date Created: Jan 1988
++ Date Last Updated: 30 Nov 1990 by Jonathan Steinbach
++ Description:
++ The Plot domain supports plotting of functions defined over a
++ real number system. A real number system is a model for the real
++ numbers and as such may be an approximation. For example
++ floating point numbers and infinite continued fractions.
++ The facilities at this point are limited to 2-dimensional plots
++ or either a single function or a parametric function.

--% function plots

plot : (F -> F,R) -> %
++ plot(f,a..b) plots the function \spad{f(x)}
++ on the interval \spad{[a,b]}.
++
++X fp:=(t:DFLOAT):DFLOAT +-> sin(t)
++X plot(fp,-1.0..1.0)$PLOT

plot : (F -> F,R,R) -> %
++ plot(f,a..b,c..d) plots the function \spad{f(x)} on the interval
++ \spad{[a,b]}; y-range of \spad{[c,d]} is noted in Plot object.

--% multiple function plots

plot : (L(F -> F),R) -> %
++ plot([f1,...,fm],a..b) plots the functions \spad{y = f1(x)},...,
++ \spad{y = fm(x)} on the interval \spad{a..b}.

plot : (L(F -> F),R,R) -> %
++ plot([f1,...,fm],a..b,c..d) plots the functions \spad{y = f1(x)},...,
++ \spad{y = fm(x)} on the interval \spad{a..b}; y-range of \spad{[c,d]}
++ is noted in Plot object.

--% parametric plots

plot : (F -> F,F -> F,R) -> %
++ plot(f,g,a..b) plots the parametric curve \spad{x = f(t)},
++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}.

plot : (F -> F,F -> F,R,R,R) -> %
++ plot(f,g,a..b,c..d,e..f) plots the parametric curve \spad{x = f(t)},
++ \spad{y = g(t)} as t ranges over the interval \spad{[a,b]}; x-range
++ of \spad{[c,d]} and y-range of \spad{[e,f]} are noted in Plot object.

```

```

--% parametric plots

pointPlot : (F -> P,R) -> %
  ++ pointPlot(t +-> (f(t),g(t)),a..b) plots the parametric curve
  ++ \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
  ++ \spad{[a,b]}.

pointPlot : (F -> P,R,R,R) -> %
  ++ pointPlot(t +-> (f(t),g(t)),a..b,c..d,e..f) plots the parametric
  ++ curve \spad{x = f(t)}, \spad{y = g(t)} as t ranges over the interval
  ++ \spad{[a,b]}; x-range of \spad{[c,d]} and y-range of \spad{[e,f]}
  ++ are noted in Plot object.

--% polar plots

plotPolar : (F -> F,R) -> %
  ++ plotPolar(f,a..b) plots the polar curve \spad{r = f(theta)} as
  ++ theta ranges over the interval \spad{[a,b]}; this is the same as
  ++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

plotPolar : (F -> F) -> %
  ++ plotPolar(f) plots the polar curve \spad{r = f(theta)} as theta
  ++ ranges over the interval \spad{[0,2*pi]}; this is the same as
  ++ the parametric curve \spad{x = f(t)*cos(t)}, \spad{y = f(t)*sin(t)}.

plot : (% ,R) -> %          -- change the range
  ++ plot(x,r) is not documented

parametric? : % -> B
  ++ parametric? determines whether it is a parametric plot?

zoom : (% ,R) -> %
  ++ zoom(x,r) is not documented

zoom : (% ,R,R) -> %
  ++ zoom(x,r,s) is not documented

refine : (% ,R) -> %
  ++ refine(x,r) is not documented

refine : % -> %
  ++ refine(p) performs a refinement on the plot p

tRange : % -> R
  ++ tRange(p) returns the range of the parameter in a parametric plot p

minPoints : () -> I
  ++ minPoints() returns the minimum number of points in a plot

setMinPoints : I -> I

```

```

    ++ setMinPoints(i) sets the minimum number of points in a plot to i

maxPoints : () -> I
    ++ maxPoints() returns the maximum number of points in a plot

setMaxPoints : I -> I
    ++ setMaxPoints(i) sets the maximum number of points in a plot to i

screenResolution : () -> I
    ++ screenResolution() returns the screen resolution

setScreenResolution : I -> I
    ++ setScreenResolution(i) sets the screen resolution to i

adaptive? : () -> B
    ++ adaptive?() determines whether plotting be done adaptively

setAdaptive : B -> B
    ++ setAdaptive(true) turns adaptive plotting on
    ++ \spad{setAdaptive(false)} turns adaptive plotting off

numFunEvals : () -> I
    ++ numFunEvals() returns the number of points computed

debug : B -> B
    ++ debug(true) turns debug mode on
    ++ \spad{debug(false)} turns debug mode off

++ refine(x,r) is not documented

```

```

refine : % -> %
++ refine(x) is not documented

```

```

tRange : % -> R
++ tRange(p) returns the range of the parameter in a parametric plot p.

```

```

tValues : % -> L L F
++ tValues(p) returns a list of lists of the values of the parameter for

```

```

    ++ which a point is computed, one list for each curve in the plot p.

minPoints3D : () -> I
    ++ minPoints3D() returns the minimum number of points in a plot.

setMinPoints3D : I -> I
    ++ setMinPoints3D(i) sets the minimum number of points in a plot to i.

maxPoints3D : () -> I
    ++ maxPoints3D() returns the maximum number of points in a plot.

setMaxPoints3D : I -> I
    ++ setMaxPoints3D(i) sets the maximum number of points in a plot to i.

screenResolution3D : () -> I
    ++ screenResolution3D() returns the screen resolution for a 3d graph.

setScreenResolution3D : I -> I
    ++ setScreenResolution3D(i) sets the screen resolution for a 3d graph
    ++ to i.

adaptive3D? : () -> B
    ++ adaptive3D?() determines whether plotting be done adaptively.

setAdaptive3D : B -> B
    ++ setAdaptive3D(true) turns adaptive plotting on;
    ++ setAdaptive3D(false) turns adaptive plotting off.

numFunEvals3D : () -> I
    ++ numFunEvals3D() returns the number of points computed.

debug3D : B -> B
    ++ debug3D(true) turns debug mode on;
    ++ debug3D(false) turns debug mode off.

=====
Polynomial examples
=====

```

The domain constructor Polynomial (abbreviation: POLY) provides polynomials with an arbitrary number of unspecified variables.

It is used to create the default polynomial domains in Axiom. Here the coefficients are integers.

$$\begin{array}{r} x + 1 \\ x + 1 \end{array}$$

Type: Polynomial Integer

Here the coefficients have type Float.

$$\begin{array}{r} z - 2.3 \\ z - 2.3 \end{array}$$

Type: Polynomial Float

And here we have a polynomial in two variables with coefficients which have type Fraction Integer.

$$\begin{array}{r} y^{**2} - z + 3/4 \\ \quad \quad \quad 2 \quad 3 \\ - z + y + - \\ \quad \quad \quad \quad 4 \end{array}$$

Type: Polynomial Fraction Integer

The representation of objects of domains created by Polynomial is that of recursive univariate polynomials. The term univariate means "one variable". The term multivariate means "possibly more than one variable".

This recursive structure is sometimes obvious from the display of a polynomial.

$$\begin{array}{r} y^{**2} + x*y + y \\ \quad \quad \quad 2 \\ y + (x + 1)y \end{array}$$

Type: Polynomial Integer

In this example, you see that the polynomial is stored as a polynomial in y with coefficients that are polynomials in x with integer coefficients. In fact, you really don't need to worry about the representation unless you are working on an advanced application where it is critical. The polynomial types created from DistributedMultivariatePolynomial and NewDistributedMultivariatePolynomial are stored and displayed in a non-recursive manner.

You see a "flat" display of the above polynomial by converting to one of those types.

$$\begin{array}{r} \% :: DMP([y,x],INT) \\ 2 \end{array}$$

```

y  + y x + y
Type: DistributedMultivariatePolynomial([y,x],Integer)

```

We will demonstrate many of the polynomial facilities by using two polynomials with integer coefficients.

By default, the interpreter expands polynomial expressions, even if they are written in a factored format.

```

p := (y-1)**2 * x * z
      2
(x y  - 2x y + x)z
Type: Polynomial Integer

```

See Factored to see how to create objects in factored form directly.

```

q := (y-1) * x * (z+5)
      (x y - x)z + 5x y - 5x
Type: Polynomial Integer

```

The fully factored form can be recovered by using factor.

```

factor(q)
x(y - 1)(z + 5)
Type: Factored Polynomial Integer

```

This is the same name used for the operation to factor integers. Such reuse of names is called overloading and makes it much easier to think of solving problems in general ways. Axiom facilities for factoring polynomials created with Polynomial are currently restricted to the integer and rational number coefficient cases.

The standard arithmetic operations are available for polynomials.

```

p - q**2
      2 2      2      2 2      2      2      2      2
(- x y  + 2x y - x )z  + ((- 10x  + x)y  + (20x  - 2x)y - 10x  + x)z
+
      2 2      2      2
- 25x y  + 50x y - 25x
Type: Polynomial Integer

```

The operation gcd is used to compute the greatest common divisor of two polynomials.

```

gcd(p,q)
x y - x
Type: Polynomial Integer

```

In the case of p and q, the gcd is obvious from their definitions. We

factor the gcd to show this relationship better.

```
factor %
x(y - 1)
Type: Factored Polynomial Integer
```

The least common multiple is computed by using lcm.

```
lcm(p,q)
      2      2      2
(x y - 2x y + x)z + (5x y - 10x y + 5x)z
Type: Polynomial Integer
```

Use content to compute the greatest common divisor of the coefficients of the polynomial.

```
content p
1
Type: PositiveInteger
```

Many of the operations on polynomials require you to specify a variable. For example, resultant requires you to give the variable in which the polynomials should be expressed.

This computes the resultant of the values of p and q, considering them as polynomials in the variable z. They do not share a root when thought of as polynomials in z.

```
resultant(p,q,z)
      2 3      2 2      2      2
5x y - 15x y + 15x y - 5x
Type: Polynomial Integer
```

This value is 0 because as polynomials in x the polynomials have a common root.

```
resultant(p,q,x)
0
Type: Polynomial Integer
```

The data type used for the variables created by Polynomial is Symbol. As mentioned above, the representation used by Polynomial is recursive and so there is a main variable for nonconstant polynomials.

The operation mainVariable returns this variable. The return type is actually a union of Symbol and "failed".

```
mainVariable p
z
Type: Union(Symbol,...)
```

The latter branch of the union is be used if the polynomial has no variables, that is, is a constant.

```
mainVariable(1 :: POLY INT)
  "failed"
                                Type: Union("failed",...)
```

You can also use the predicate `ground?` to test whether a polynomial is in fact a member of its ground ring.

```
ground? p
  false
                                Type: Boolean
```

```
ground?(1 :: POLY INT)
  true
                                Type: Boolean
```

The complete list of variables actually used in a particular polynomial is returned by `variables`. For constant polynomials, this list is empty.

```
variables p
  [z,y,x]
                                Type: List Symbol
```

The degree operation returns the degree of a polynomial in a specific variable.

```
degree(p,x)
  1
                                Type: PositiveInteger
```

```
degree(p,y)
  2
                                Type: PositiveInteger
```

```
degree(p,z)
  1
                                Type: PositiveInteger
```

If you give a list of variables for the second argument, a list of the degrees in those variables is returned.

```
degree(p,[x,y,z])
  [1,2,1]
                                Type: List NonNegativeInteger
```

The minimum degree of a variable in a polynomial is computed using `minimumDegree`.

```

minimumDegree(p,z)
1
Type: PositiveInteger

```

The total degree of a polynomial is returned by totalDegree.

```

totalDegree p
4
Type: PositiveInteger

```

It is often convenient to think of a polynomial as a leading monomial plus the remaining terms.

```

leadingMonomial p
2
x y z
Type: Polynomial Integer

```

The reductum operation returns a polynomial consisting of the sum of the monomials after the first.

```

reductum p
(- 2x y + x)z
Type: Polynomial Integer

```

These have the obvious relationship that the original polynomial is equal to the leading monomial plus the reductum.

```

p - leadingMonomial p - reductum p
0
Type: Polynomial Integer

```

The value returned by leadingMonomial includes the coefficient of that term. This is extracted by using leadingCoefficient on the original polynomial.

```

leadingCoefficient p
1
Type: PositiveInteger

```

The operation eval is used to substitute a value for a variable in a polynomial.

```

p
2
(x y - 2x y + x)z
Type: Polynomial Integer

```

This value may be another variable, a constant or a polynomial.

```

eval(p,x,w)

```

```

      2
(w y  - 2w y + w)z
      Type: Polynomial Integer

```

```

eval(p,x,1)
      2
(y  - 2y + 1)z
      Type: Polynomial Integer

```

Actually, all the things being substituted are just polynomials, some more trivial than others.

```

eval(p,x,y^2 - 1)
      4      3
(y  - 2y  + 2y - 1)z
      Type: Polynomial Integer

```

Derivatives are computed using the D operation.

```

D(p,x)
      2
(y  - 2y + 1)z
      Type: Polynomial Integer

```

The first argument is the polynomial and the second is the variable.

```

D(p,y)
(2x y - 2x)z
      Type: Polynomial Integer

```

Even if the polynomial has only one variable, you must specify it.

```

D(p,z)
      2
x y  - 2x y + x
      Type: Polynomial Integer

```

Integration of polynomials is similar and the integrate operation is used.

Integration requires that the coefficients support division. Axiom converts polynomials over the integers to polynomials over the rational numbers before integrating them.

```

integrate(p,y)
      1      3      2
(- x y  - x y  + x y)z
      3
      Type: Polynomial Fraction Integer

```

It is not possible, in general, to divide two polynomials. In our

example using polynomials over the integers, the operation `monicDivide` divides a polynomial by a monic polynomial (that is, a polynomial with leading coefficient equal to 1). The result is a record of the quotient and remainder of the division.

You must specify the variable in which to express the polynomial.

```
qr := monicDivide(p,x+1,x)
      2
[quotient= (y - 2y + 1)z,remainder= (- y + 2y - 1)z]
Type: Record(quotient: Polynomial Integer,remainder: Polynomial Integer)
```

The selectors of the components of the record are `quotient` and `remainder`. Issue this to extract the remainder.

```
qr.remainder
      2
(- y + 2y - 1)z
Type: Polynomial Integer
```

Now that we can extract the components, we can demonstrate the relationship among them and the arguments to our original expression

```
qr := monicDivide(p,x+1,x).
```

```
p - ((x+1) * qr.quotient + qr.remainder)
0
Type: Polynomial Integer
```

If the `/` operator is used with polynomials, a fraction object is created. In this example, the result is an object of type `Fraction Polynomial Integer`.

```
p/q
(y - 1)z
-----
z + 5
Type: Fraction Polynomial Integer
```

If you use rational numbers as polynomial coefficients, the resulting object is of type `Polynomial Fraction Integer`.

```
(2/3) * x**2 - y + 4/5
      2 2 4
- y + - x + -
      3 5
Type: Polynomial Fraction Integer
```

This can be converted to a fraction of polynomials and back again, if required.

```
% :: FRAC POLY INT
      2
- 15y + 10x  + 12
-----
      15
```

Type: Fraction Polynomial Integer

```
% :: POLY FRAC INT
      2 2 4
- y + - x  + -
      3 5
```

Type: Polynomial Fraction Integer

To convert the coefficients to floating point, map the numeric operation on the coefficients of the polynomial.

```
map(numeric,%)
- 1.0 y + 0.6666666666 6666666667 x  + 0.8
Type: Polynomial Float
```

PolynomialIdeals examples

=====

This domain represents polynomial ideals with coefficients in any field and supports the basic ideal operations, including intersection sum and quotient.

An ideal is represented by a list of polynomials (the generators of the ideal) and a boolean that is true if the generators are a Groebner basis.

The algorithms used are based on Groebner basis computations. The ordering is determined by the datatype of the input polynomials. Users may use refinements of total degree orderings.

  F : Field
  Expon : OrderedAbelianMonoidSup
  VarSet : OrderedSet
  DPoly : PolynomialCategory(F,Expon,VarSet)

  SUP ==> SparseUnivariatePolynomial(DPoly)
  NNI ==> NonNegativeInteger
  Z ==> Integer
  P ==> Polynomial F
  
```

```

MF ==> Matrix(F)
ST ==> SuchThat(List P, List Equation P)
GenMPos ==> Record(mval:MF, invmval:MF, genIdeal:Ideal)
Ideal ==> %

SIG ==> SetCategory with

"*" : (Ideal, Ideal) -> Ideal
++ I * J computes the product of the ideal I and J.

"**" : (Ideal, NNI) -> Ideal
++ I ** n computes the nth power of the ideal I.

"+" : (Ideal, Ideal) -> Ideal
++ I + J computes the ideal generated by the union of I and J.

one? : Ideal -> Boolean
++ one?(I) tests whether the ideal I is the unit ideal,
++ contains 1.

zero? : Ideal -> Boolean
++ zero?(I) tests whether the ideal I is the zero ideal

element? : (DPoly, Ideal) -> Boolean
++ element?(f, I) tests whether the polynomial f belongs to
++ the ideal I.

in? : (Ideal, Ideal) -> Boolean
++ in?(I, J) tests if the ideal I is contained in the ideal J.

inRadical? : (DPoly, Ideal) -> Boolean
++ inRadical?(f, I) tests if some power of the polynomial f
++ belongs to the ideal I.

zeroDim? : (Ideal, List VarSet) -> Boolean
++ zeroDim?(I, lvar) tests if the ideal I is zero dimensional,
++ all its associated primes are maximal,
++ in the ring \spad{F[lvar]}

zeroDim? : Ideal -> Boolean
++ zeroDim?(I) tests if the ideal I is zero dimensional,
++ all its associated primes are maximal,
++ in the ring \spad{F[lvar]},
++ where lvar are the variables appearing in I

intersect : (Ideal, Ideal) -> Ideal
++ intersect(I, J) computes the intersection of the ideals I and J.

intersect : List(Ideal) -> Ideal
++ intersect(LI) computes the intersection of the list of ideals LI.

```

```

quotient : (Ideal,Ideal) -> Ideal
++ quotient(I,J) computes the quotient of the ideals I and J,
++ \spad{(I:J)}.

quotient : (Ideal,DPoly) -> Ideal
++ quotient(I,f) computes the quotient of the ideal I by the principal
++ ideal generated by the polynomial f, \spad{(I:(f))}.

groebner : Ideal -> Ideal
++ groebner(I) returns a set of generators of I that are a
++ Groebner basis for I.

generalPosition : (Ideal,List VarSet) -> GenMPos
++ generalPosition(I,listvar) perform a random linear
++ transformation on the variables in listvar and returns
++ the transformed ideal along with the change of basis matrix.

backOldPos : GenMPos -> Ideal
++ backOldPos(genPos) takes the result
++ produced by generalPosition from PolynomialIdeals
++ and performs the inverse transformation, returning the original ideal
++ \spad{backOldPos(generalPosition(I,listvar))} = I.

dimension : (Ideal,List VarSet) -> Z
++ dimension(I,lvar) gives the dimension of the ideal I,
++ in the ring \spad{F[lvar]}

dimension : Ideal -> Z
++ dimension(I) gives the dimension of the ideal I.
++ in the ring \spad{F[lvar]}, where lvar are the variables
++ appearing in I

leadingIdeal : Ideal -> Ideal
++ leadingIdeal(I) is the ideal generated by the
++ leading terms of the elements of the ideal I.

ideal : List DPoly -> Ideal
++ ideal(polyList) constructs the ideal generated by the list
++ of polynomials polyList.

groebnerIdeal : List DPoly -> Ideal
++ groebnerIdeal(polyList) constructs the ideal generated by the list
++ of polynomials polyList which are assumed to be a Groebner
++ basis.
++ Note: this operation avoids a Groebner basis computation.

groebner? : Ideal -> Boolean
++ groebner?(I) tests if the generators of the ideal I are a
++ Groebner basis.

```

```

generators : Ideal -> List DPoly
  ++ generators(I) returns a list of generators for the ideal I.

coerce : List DPoly -> Ideal
  ++ coerce(polyList) converts the list of polynomials polyList
  ++ to an ideal.

saturate : (Ideal,DPoly) -> Ideal
  ++ saturate(I,f) is the saturation of the ideal I
  ++ with respect to the multiplicative
  ++ set generated by the polynomial f.

saturate : (Ideal,DPoly,List VarSet) -> Ideal
  ++ saturate(I,f,lvar) is the saturation with respect to the prime
  ++ principal ideal which is generated by f in the polynomial ring
  ++ \spad{F[lvar]}.

if VarSet has ConvertibleTo Symbol then

  relationsIdeal : List DPoly -> ST
    ++ relationsIdeal(polyList) returns the ideal of relations among the
    ++ polynomials in polyList.

=====

PolynomialRing examples

=====

This domain represents generalized polynomials with coefficients (from a not necessarily commutative ring), and terms indexed by their exponents (from an arbitrary ordered abelian monoid).

This type is used, for example, by the DistributedMultivariatePolynomial domain where the exponent domain is a direct product of non negative integers.

— Product.help —

=====

Product examples

=====

The direct product of two functions over the same domain is another function over that domain whose co-domain is the product of their co-domains.

So we can define two functions, f and g, that go from INT -> INT

```
f:=(x:INT):INT +-> 3*x
g:=(x:INT):INT +-> x^3
```

so

```
f(3) is 9
g(3) is 27
```

and we can construct the direct product of those functions h=f,g

```
h(x:INT):Product(INT,INT) == makeprod(f x, g x)
```

so

```
h(3) is (9,27)
```

See Also:

```

=====
PseudoAlgebraicClosureOfAlgExtOfRationalNumber examples
=====
```

This domain implement dynamic extension over the
PseudoAlgebraicClosureOfRationalNumber.

A tower extension T of the ground field K is any sequence of field
extension

($T : K_0, K_1, \dots, K_i, \dots, K_n$)
where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of
 K_{i-1} of degree > 1 and defined by an irreducible polynomial
 $p(Z)$ in K_{i-1} .

Two towers

($T_1 : K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1}$)

and

($T_2 : K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2}$)

are said to be related if

$T_1 \leq T_2$ (or $T_1 \geq T_2$),

that is if

$K_{i1} = K_{i2}$ for $i = 1, 2, \dots, n_1$

(or $i = 1, 2, \dots, n_2$). Any algebraic operations defined for several elements
are only defined if all of the concerned elements are coming from
a set of related tower extensions.

=====
PseudoAlgebraicClosureOfFiniteField examples
=====

```

This domain implement dynamic extension using the simple notion of tower extensions. A tower extension T of the ground field K is any sequence of field extension

$$(T : K_0, K_1, \dots, K_{i-1}, K_i)$$

where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of K_{i-1} of degree > 1 and defined by an irreducible polynomial $p(Z)$ in K_{i-1} .

Two towers

(T_1: K_01, K_11, ..., K_i1, ..., K_n1)

and

(T_2: K_02, K_12, ..., K_i2, ..., K_n2)

are said to be related if

T_1 ≤ T_2 (or T_1 ≥ T_2),

that is if

K_i1 = K_i2 for i=1,2,...,n1

(or i=1,2,...,n2). Any algebraic operations defined for several elements

are only defined if all of the concerned elements are coming from

a set of related tower extensions.

=====

```

This domain implements dynamic extension using the simple notion of tower extensions. A tower extension T of the ground field K is any sequence of field extension

$(T : K_0, K_1, \dots, K_{i-1}, K_i, \dots, K_n)$

where $K_0 = K$ and for $i = 1, 2, \dots, n$, K_i is an extension of K_{i-1} of degree > 1 and defined by an irreducible polynomial $p(Z)$ in K_{i-1} .

Two towers

$(T_1: K_{01}, K_{11}, \dots, K_{i1}, \dots, K_{n1})$

and

$(T_2: K_{02}, K_{12}, \dots, K_{i2}, \dots, K_{n2})$

are said to be related if

$T_1 \leq T_2$ (or $T_1 \geq T_2$),

that is if

$K_{i1} = K_{i2}$ for $i = 1, 2, \dots, n_1$ (or $i = 1, 2, \dots, n_2$).

Any algebraic operations defined for several elements are only defined if all of the concerned elements are coming from a set of related tower extensions.

=====

QuasiAlgebraicSet examples

=====

QuasiAlgebraicSet constructs a domain representing quasi-algebraic sets, which is the intersection of a Zariski closed set, defined as the common zeros of a given list of polynomials (the defining polynomials for equations), and a principal Zariski open set, defined as the complement of the common zeros of a polynomial f (the defining polynomial for the inequation).

This domain provides simplification of a user-given representation using groebner basis computations.

There are two simplification routines: the first function `idealSimplify` uses groebner basis of ideals alone, while the second, `simplify` uses both groebner basis and factorization. The resulting defining equations L always form a groebner basis, and the resulting defining inequation f is always reduced. The function `simplify` may be applied several times if desired. A third simplification routine `radicalSimplify` is provided in `QuasiAlgebraicSet2` for comparison study only, as it is inefficient compared to the other two, as well as is restricted to only certain coefficient domains. For detail analysis and a comparison of the three methods, please consult the reference cited.

A polynomial function q defined on the quasi-algebraic set is equivalent to its reduced form with respect to L . While this may be obtained using the usual normal form algorithm, there is no canonical form for q .

The ordering in groebner basis computation is determined by the data

type of the input polynomials. If it is possible we suggest to use refinements of total degree orderings.

++ Author: William Sit
++ Date Created: March 13, 1992
++ Date Last Updated: June 12, 1992
++ References: William Sit, "An Algorithm for Parametric Linear Systems"
++             J. Sym. Comp., April, 1992
++ Description:
++ \spadtype{QuasiAlgebraicSet} constructs a domain representing
++ quasi-algebraic sets, which is the intersection of a Zariski
++ closed set, defined as the common zeros of a given list of
++ polynomials (the defining polynomials for equations), and a principal
++ Zariski open set, defined as the complement of the common
++ zeros of a polynomial f (the defining polynomial for the inequation).
++ This domain provides simplification of a user-given representation
++ using groebner basis computations.
++ There are two simplification routines: the first function
++ \spadfun{idealSimplify} uses groebner
  
```

```

++ basis of ideals alone, while the second, \spadfun{simplify} uses both
++ groebner basis and factorization. The resulting defining equations L
++ always form a groebner basis, and the resulting defining
++ inequation f is always reduced. The function \spadfun{simplify} may
++ be applied several times if desired. A third simplification
++ routine \spadfun{radicalSimplify} is provided in
++ \spadtype{QuasiAlgebraicSet2} for comparison study only,
++ as it is inefficient compared to the other two, as well as is
++ restricted to only certain coefficient domains. For detail analysis
++ and a comparison of the three methods, please consult the reference
++ cited.
++
++ A polynomial function q defined on the quasi-algebraic set
++ is equivalent to its reduced form with respect to L. While
++ this may be obtained using the usual normal form
++ algorithm, there is no canonical form for q.
++
++ The ordering in groebner basis computation is determined by
++ the data type of the input polynomials. If it is possible
++ we suggest to use refinements of total degree orderings.

QuasiAlgebraicSet(R, Var,Expon,Dpoly) : SIG == CODE where
  R : GcdDomain
  Var : OrderedSet
  Expon : OrderedAbelianMonoidSup
  Dpoly : PolynomialCategory(R,Expon,Var)

  NNI      ==> NonNegativeInteger
  newExpon ==> Product(NNI,Expon)
  newPoly  ==> PolynomialRing(R,newExpon)
  Ex       ==> OutputForm
  mrf      ==> MultivariateFactorize(Var,Expon,R,Dpoly)
  Status   ==> Union(Boolean,"failed") -- empty or not, or don't know

SIG ==> Join(SetCategory, CoercibleTo OutputForm) with
  --- should be Object instead of SetCategory, bug in LIST Object ---
  --- equality is not implemented ---

empty : () -> $
  ++ empty() returns the empty quasi-algebraic set

quasiAlgebraicSet : (List Dpoly, Dpoly) -> $
  ++ quasiAlgebraicSet(pl,q) returns the quasi-algebraic set
  ++ with defining equations  $p = 0$  for  $p$  belonging to the list pl, and
  ++ defining inequation  $q \neq 0$ .

status : $ -> Status
  ++ status(s) returns true if the quasi-algebraic set is empty,
  ++ false if it is not, and "failed" if not yet known

```

```

setStatus : ($, Status) -> $
  ++ setStatus(s,t) returns the same representation for s, but
  ++ asserts the following: if t is true, then s is empty,
  ++ if t is false, then s is non-empty, and if t = "failed",
  ++ then no assertion is made (that is, "don't know").
  ++ Note: for internal use only, with care.

empty? : $ -> Boolean
  ++ empty?(s) returns
  ++ true if the quasialgebraic set s has no points,
  ++ and false otherwise.

definingEquations : $ -> List Dpoly
  ++ definingEquations(s) returns a list of defining polynomials
  ++ for equations, that is, for the Zariski closed part of s.

definingInequation : $ -> Dpoly
  ++ definingInequation(s) returns a single defining polynomial for the
  ++ inequation, that is, the Zariski open part of s.

idealSimplify : $ -> $
  ++ idealSimplify(s) returns a different and presumably simpler
  ++ representation of s with the defining polynomials for the
  ++ equations
  ++ forming a groebner basis, and the defining polynomial for the
  ++ inequation reduced with respect to the basis, using Buchberger's
  ++ algorithm.

if (R has EuclideanDomain) and (R has CharacteristicZero) then

  simplify : $ -> $
    ++ simplify(s) returns a different and presumably simpler
    ++ representation of s with the defining polynomials for the
    ++ equations
    ++ forming a groebner basis, and the defining polynomial for the
    ++ inequation reduced with respect to the basis, using a heuristic
    ++ algorithm based on factoring.

Quaternion examples

=====

The domain constructor Quaternion implements quaternions over commutative rings.

The basic operation for creating quaternions is quatern. This is a quaternion over the rational numbers.

```

q := quatern(2/11,-8,3/4,1)
      2      3
-- - 8i + - j + k
     11      4

```

Type: Quaternion Fraction Integer

The four arguments are the real part, the i imaginary part, the j imaginary part, and the k imaginary part, respectively.

```

[real q, imagI q, imagJ q, imagK q]
      2      3
[--, - 8, -, 1]
     11      4

```

Type: List Fraction Integer

Because q is over the rationals (and nonzero), you can invert it.

```

inv q
  352      15488      484      1936
----- + ----- i - ----- j - ----- k
126993  126993  42331  126993
Type: Quaternion Fraction Integer

```

The usual arithmetic (ring) operations are available

```

q^6
  2029490709319345  48251690851  144755072553  48251690851
----- - ----- i + ----- j + ----- k
7256313856      1288408      41229056      10307264
Type: Quaternion Fraction Integer

```

```

r := quatern(-2,3,23/9,-89); q + r
  20      119
-- - 5i + --- j - 88k
11      36
Type: Quaternion Fraction Integer

```

In general, multiplication is not commutative.

```

q * r - r * q
  2495      817
----- i - 1418j - --- k
18      18
Type: Quaternion Fraction Integer

```

There are no predefined constants for the imaginary i, j, and k parts, but you can easily define them.

```

i:=quatern(0,1,0,0)
i
Type: Quaternion Integer

```

```

j:=quatern(0,0,1,0)
j
Type: Quaternion Integer

```

```

k:=quatern(0,0,0,1)
k
Type: Quaternion Integer

```

These satisfy the normal identities.

```

[i*i, j*j, k*k, i*j, j*k, k*i, q*i]
      2      3
[- 1,- 1,- 1,k,i,j,8 + -- i + j - - k]
      11      4
Type: List Quaternion Fraction Integer

```

The norm is the quaternion times its conjugate.

```
norm q
 126993
-----
 1936
Type: Fraction Integer
```

```
conjugate q
 2      3
-- + 8i - - j - k
11      4
Type: Quaternion Fraction Integer
```

```
q * %
 126993
-----
 1936
Type: Quaternion Fraction Integer
```

— Queue.help —

=====

Queue examples

=====

A Queue object is represented as a list ordered by first-in, first-out. It operates like a line of people, where the "next" person is the one at the front of the line.

Here we create an queue of integers from a list. Notice that the order in the list is the order in the queue.

```

a:Queue INT:= queue [1,2,3,4,5]
[1,2,3,4,5]

```

We can remove the top of the queue using dequeue!:

```

dequeue! a
1

```

Notice that the use of dequeue! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data structure is changed).

```

a
[2,3,4,5]

```

The `extract!` operation is another name for the `pop!` operation and has the same effect. This operation treats the queue as a `BagAggregate`:

```
extract! a
2
```

and you can see that it also has destructively modified the queue:

```
a
[3,4,5]
```

Next we use `enqueue!` to add a new element to the end of the queue:

```
push!(9,a)
9
```

Again, the `push!` operation is destructive so the queue is changed:

```
a
[3,4,5,9]
```

Another name for `enqueue!` is `insert!`, which treats the queue as a `BagAggregate`:

```
insert!(8,a)
[3,4,5,9,8]
```

and it modifies the queue:

```
a
[3,4,5,9,8]
```

The `inspect` function returns the top of the queue without modification, viewed as a `BagAggregate`:

```
inspect a
8
```

The `empty?` operation returns `true` only if there are no element on the queue, otherwise it returns `false`:

```
empty? a
false
```

The `front` operation returns the front of the queue without modification:

```
front a
3
```

The `back` operation returns the back of the queue without modification:

```
back a
      8
```

The rotate! operation moves the item at the front of the queue to the back of the queue:

```
rotate! a
      [4,5,9,8,3]
```

The # (length) operation:

```
#a
    5
```

The length operation does the same thing:

```
length a
      5
```

The less? predicate will compare the queue length to an integer:

```
less?(a,9)
      true
```

The more? predicate will compare the queue length to an integer:

```
more?(a,9)
      false
```

The size? operation will compare the queue length to an integer:

```
size?(a,#a)
      true
```

and since the last computation must always be true we try:

```
size?(a,9)
      false
```

The parts function will return the queue as a list of its elements:

```
parts a
      [8,9,3,4,5]
```

If we have a BagAggregate of elements we can use it to construct a queue:

```
bag([1,2,3,4,5])$Queue(INT)
      [1,2,3,4,5]
```

The `empty` function will construct an empty queue of a given type:

```
b:=empty()$(Queue INT)
[]
```

and the `empty?` predicate allows us to find out if a queue is empty:

```
empty? b
true
```

The `sample` function returns a sample, empty queue:

```
sample()$(Queue(INT))
[]
```

We can copy a queue and it does not share storage so subsequent modifications of the original queue will not affect the copy:

```
c:=copy a
[4,5,9,8,3]
```

The `eq?` function is only true if the lists are the same reference, so even though `c` is a copy of `a`, they are not the same:

```
eq?(a,c)
false
```

However, `a` clearly shares a reference with itself:

```
eq?(a,a)
true
```

But we can compare `a` and `c` for equality:

```
(a=c)@Boolean
true
```

and clearly `a` is equal to itself:

```
(a=a)@Boolean
true
```

and since `a` and `c` are equal, they are clearly NOT not-equal:

```
a~=c
false
```

We can use the `any?` function to see if a predicate is true for any element:

```
any?(x+-(x=4),a)
```

```
true
```

or false for every element:

```
any?(x+-(x=11),a)
false
```

We can use the every? function to check every element satisfies a predicate:

```
every?(x+-(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+-(x>2),a)
5
```

You can also map a function over every element, returning a new queue:

```
map(x+>x+10,a)
[14,15,19,18,13]
```

Notice that the original queue is unchanged:

```
a
[4,5,9,8,3]
```

You can use map! to map a function over every element and change the original queue since map! is destructive:

```
map!(x+>x+10,a)
[14,15,19,18,13]
```

o

Notice that the original queue has been changed:

```
a
[14,15,19,18,13]
```

The member function can also get the element of the queue as a list:

```
members a
[18,19,13,14,15]
```

and using member? we can test if the queue holds a given element:

```
member?(14,a)
true
```

=====

RadixExpansion examples

=====

It possible to expand numbers in general bases.

Here we expand 111 in base 5. This means

$$10^2 + 10^1 + 10^0 = 4 * 5^2 + 2 * 5^1 + 5^0$$

```
111::RadixExpansion(5)
```

```
421
```

```
Type: RadixExpansion 5
```

You can expand fractions to form repeating expansions.

```
(5/24)::RadixExpansion(2)
```

```
--
0.00110
```

```
Type: RadixExpansion 2
```

```
(5/24)::RadixExpansion(3)
```

```
--
0.012
```

```
Type: RadixExpansion 3
```

```
(5/24)::RadixExpansion(8)
```

0.152⁻⁻

Type: RadixExpansion 8

(5/24)::RadixExpansion(10)

0.2083⁻

Type: RadixExpansion 10

For bases from 11 to 36 the letters A through Z are used.

(5/24)::RadixExpansion(12)

0.26

Type: RadixExpansion 12

(5/24)::RadixExpansion(16)

0.35⁻

Type: RadixExpansion 16

(5/24)::RadixExpansion(36)

0.7I

Type: RadixExpansion 36

For bases greater than 36, the ragits are separated by blanks.

(5/24)::RadixExpansion(38)

0 . 7 34 31 25 12⁻⁻⁻⁻⁻

Type: RadixExpansion 38

The RadixExpansion type provides operations to obtain the individual ragits. Here is a rational number in base 8.

a := (76543/210)::RadixExpansion(8)

554.37307⁻⁻⁻⁻

Type: RadixExpansion 8

The operation wholeRagits returns a list of the ragits for the integral part of the number.

w := wholeRagits a
[5,5,4]

Type: List Integer

The operations prefixRagits and cycleRagits return lists of the initial and repeating ragits in the fractional part of the number.

f0 := prefixRagits a

[3]

Type: List Integer

```
f1 := cycleRagits a
      [7,3,0,7]
```

Type: List Integer

You can construct any radix expansion by giving the whole, prefix and cycle parts. The declaration is necessary to let Axiom know the base of the ragits.

```
u:RadixExpansion(8):=wholeRadix(w)+fractRadix(f0,f1)
```

```
-----
554.37307
```

Type: RadixExpansion 8

If there is no repeating part, then the list [0] should be used.

```
v: RadixExpansion(12) := fractRadix([1,2,3,11], [0])
```

```
-
0.123B0
```

Type: RadixExpansion 12

If you are not interested in the repeating nature of the expansion, an infinite stream of ragits can be obtained using fractRagits.

```
fractRagits(u)
```

```
-----
[3,7,3,0,7,7]
```

Type: Stream Integer

Of course, it's possible to recover the fraction representation:

```
a :: Fraction(Integer)
```

```
76543
```

```
-----
```

```
210
```

Type: Fraction Integer

— domain RADIX RadixExpansion —

```

)abbrev domain RADIX RadixExpansion
++ Author: Stephen M. Watt
++ Date Created: October 1986
++ Date Last Updated: May 15, 1991
++ Description:
++ This domain allows rational numbers to be presented as repeating
++ decimal expansions or more generally as repeating expansions in any base.

```

```

RadixExpansion(bb) : SIG == CODE where
  bb : Integer

```

```

I  ==> Integer
NNI ==> NonNegativeInteger
OUT ==> OutputForm
RN  ==> Fraction Integer
ST  ==> Stream Integer

```

```

QuoRem ==> Record(quotient: Integer, remainder: Integer)

SIG ==> QuotientFieldCategory(Integer) with

  coerce : % -> Fraction Integer
    ++ coerce(rx) converts a radix expansion to a rational number.

  fractionPart : % -> Fraction Integer
    ++ fractionPart(rx) returns the fractional part of a radix expansion.

  wholeRagits : % -> List Integer
    ++ wholeRagits(rx) returns the ragits of the integer part
    ++ of a radix expansion.

  fractRagits : % -> Stream Integer
    ++ fractRagits(rx) returns the ragits of the fractional part
    ++ of a radix expansion.

  prefixRagits : % -> List Integer
    ++ prefixRagits(rx) returns the non-cyclic part of the ragits
    ++ of the fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{prefixRagits(x)}=[1,0]}.

  cycleRagits : % -> List Integer
    ++ cycleRagits(rx) returns the cyclic part of the ragits of the
    ++ fractional part of a radix expansion.
    ++ For example, if \spad{x = 3/28 = 0.10 714285 714285 ...},
    ++ then \spad{cycleRagits(x)} = [7,1,4,2,8,5]}.

  wholeRadix : List Integer -> %
    ++ wholeRadix(l) creates an integral radix expansion from a list
    ++ of ragits.
    ++ For example, \spad{wholeRadix([1,3,4])} will return \spad{134}.

  fractRadix : (List Integer, List Integer) -> %
    ++ fractRadix(pre,cyc) creates a fractional radix expansion
    ++ from a list of prefix ragits and a list of cyclic ragits.
    ++ for example, \spad{fractRadix([1],[6])} will return
    ++ \spad{0.16666666...}.

domain RECLOS RealClosure

The domain constructore **RealClosure** by Renaud Rioboo (University of Paris 6, France) provides the real closure of an ordered field. The implementation is based on interval arithmetic. Moreover, the design of this constructor and its related packages allows an easy use of other codings for real algebraic numbers. ordered field

The RealClosure domain is the end-user code, it provides usual arithmetics with real algebraic numbers, along with the functionalities of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute (approximate) or relative (realtivApprox).

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every cretaion function raises a new "real root". This has the effect that when you type something like $\sqrt{2} + \sqrt{2}$ you have two new variables which happen to be equal. To avoid this name the expression such as in $s2 := \sqrt{2} ; s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file reclos.input show some basic use of the package. This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, inparticular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Betas versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms

and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

RealClosure examples

=====

The Real Closure 1.0 package provided by Renaud Rioboo consists of different packages, categories and domains :

The package RealPolynomialUtilitiesPackage which needs a Field F and a UnivariatePolynomialCategory domain with coefficients in F. It computes some simple functions such as Sturm and Sylvester sequences sturmSequence, sylvesterSequence.

The category RealRootCharacterizationCategory provides abstract functions to work with "real roots" of univariate polynomials. These resemble variables with some functionality needed to compute important operations.

The category RealClosedField provides common operations available over real closed fiels. These include finding all the roots of a univariate polynomial, taking square (and higher) roots, ...

The domain RightOpenIntervalRootCharacterization is the main code that provides the functionality of RealRootCharacterizationCategory for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

The RealClosure domain is the end-user code. It provides usual arithmetic with real algebraic numbers, along with the functionality of a real closed field. It also provides functions to approximate a real algebraic number by an element of the base field. This approximation may either be absolute, approximate or relative (relativeApprox).

=====

CAVEATS

=====

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like $\sqrt{2} + \sqrt{2}$ you have two new variables which happen to be equal. To avoid this name the expression such as in $s2 := \sqrt{2}$; $s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which seems most natural to you.

=====

LIMITATIONS

=====

This packages uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

=====

EXAMPLES

=====

We shall work with the real closure of the ordered field of rational numbers.

```
Ran := RECLOS(FRAC INT)
      RealClosure Fraction Integer
                        Type: Domain
```

Some simple signs for square roots, these correspond to an extension of degree 16 of the rational numbers. Examples provided by J. Abbot.

```
fourSquares(a:Ran,b:Ran,c:Ran,d:Ran):Ran==sqrt(a)+sqrt(b)-sqrt(c)-sqrt(d)
                        Type: Void
```

These produce values very close to zero.

```
squareDiff1 := fourSquares(73,548,60,586)
      +---+ +---+ +---+ +---+
      - \|586 - \|60 + \|548 + \|73
                        Type: RealClosure Fraction Integer
```

```
recip(squareDiff1)
      +---+ +---+ +---+ +---+

— domain **RECLOS** RealClosure —

```

)abbrev domain RECLOS RealClosure
++ Author: Renaud Rioboo
++ Date Created: summer 1988
++ Date Last Updated: January 2004
++ References:
++ Riob92 Real algebraic closure of an ordered field,
++ Implementation in Axiom
++ Emir04 Comparing real algebraic numbers of small degree
++ Description:
++ This domain implements the real closure of an ordered field.

```

```

++ Note:
++ The code here is generic it does not depend of the way the operations
++ are done. The two macros PME and SEG should be passed as functorial
++ arguments to the domain. It does not help much to write a category
++ since non trivial methods cannot be placed there either.

```

```

)abbrev domain RGCHAIN RegularChain
++ Author: Marc Moreno Maza
++ Date Created: 01/1999
++ Date Last Updated: 23/01/1999
++ Description:
++ A domain for regular chains (regular triangular sets) over
++ a Gcd-Domain and with a fix list of variables.
++ This is just a front-end for the \spadtype{RegularTriangularSet}
++ domain constructor.

RegularChain(R,ls) : SIG == CODE where
  R : GcdDomain
  ls : List Symbol

  V ==> OrderedVariableList ls
  E ==> IndexedExponents V
  P ==> NewSparseMultivariatePolynomial(R,V)
  TS ==> RegularTriangularSet(R,E,V,P)

  SIG ==> RegularTriangularSetCategory(R,E,V,P) with

    zeroSetSplit : (List P, Boolean, Boolean) -> List $
      ++ \spad{zeroSetSplit(lp,clos?,info?)} returns a list \spad{lts} of
      ++ regular chains such that the union of the closures of their regular
      ++ zero sets equals the affine variety associated with \spad{lp}.
      ++ Moreover, if \spad{clos?} is \spad{false} then the union of the
      ++ regular zero set of the \spad{ts} (for \spad{ts} in \spad{lts})
      ++ equals this variety.
      ++ If \spad{info?} is \spad{true} then some information is
      ++ displayed during the computations. See
      ++ zeroSetSplit from RegularTriangularSet.

  CODE ==> RegularTriangularSet(R,E,V,P)

—————

domain REGSET RegularTriangularSet

Several domain constructors implement regular triangular sets (or regular chains). Among them **RegularTriangularSet** and **SquareFreeRegularTriangularSet**. They also implement an algorithm by Marc Moreno Maza for computing triangular decompositions of polynomial systems. This method is refined in the package **LazardSetSolvingPackage** in order to produce decompositions by means of Lazard triangular sets.

=====

RegularTriangularSet examples

=====

The RegularTriangularSet domain constructor implements regular triangular sets. These particular triangular sets were introduced by M. Kalkbrener (1991) in his PhD Thesis under the name regular chains. Regular chains and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The RegularTriangularSet constructor also provides a new method (by the third author) for solving polynomial system by means of regular chains. This method has two ways of solving. One has the same specifications as Kalkbrener's algorithm (1991) and the other is closer to Lazard's method (Discr. App. Math, 1991). Moreover, this new method removes redundant component from the decompositions when this is not too expensive. This is always the case with square-free regular chains. So if you want to obtain decompositions without redundant components just use the SquareFreeRegularTriangularSet domain constructor or the LazardSetSolvingPackage package constructor. See also the LexTriangularPackage and ZeroDimensionalSolvePackage for the case of algebraic systems with a finite number of (complex) solutions.

One of the main features of regular triangular sets is that they naturally define towers of simple extensions of a field. This allows to perform with multivariate polynomials the same kind of operations as one can do in an EuclideanDomain.

The RegularTriangularSet constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category GcdDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. The third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The last one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The abbreviation for RegularTriangularSet is REGSET. See also the constructor RegularChain which only takes two arguments, the coefficient ring and the ordered set of variables; in that case, polynomials are necessarily built with the NewSparseMultivariatePolynomial domain constructor.

We shall explain now how to use the constructor REGSET and how to read the decomposition of a polynomial system by means of regular sets.

Let us give some examples. We start with an easy one (Donati-Traverso) in order to understand the two ways of solving polynomial systems provided by the REGSET constructor.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
OrderedVariableList [x,y,z,t]
Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
      NewSparseMultivariatePolynomial(Integer, OrderedVariableList [x,y,z,t])
                                     Type: Domain
```

Let the variables be polynomial.

```
x: P := 'x
x
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

y: P := 'y
y
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

z: P := 'z
z
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

t: P := 't
t
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])
```

Now call the RegularTriangularSet domain constructor.

```
T := REGSET(R,E,V,P)
RegularTriangularSet(Integer, IndexedExponents OrderedVariableList [x,y,z,t], 0
rderedVariableList [x,y,z,t], NewSparseMultivariatePolynomial(Integer, OrderedV
ariableList [x,y,z,t]))
                                     Type: Domain
```

Define a polynomial system.

```
p1 := x ** 31 - x ** 6 - x - y
      31      6
      x  - x  - x - y
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

p2 := x ** 8 - z
      8
      x  - z
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
      10
```

```

x      - t
Type: NewSparseMultivariatePolynomial(Integer,
                                         OrderedVariableList [x,y,z,t])

lp := [p1, p2, p3]
      31      6      8      10
[x  - x  - x - y, x  - z, x  - t]
Type: List NewSparseMultivariatePolynomial(Integer,
                                         OrderedVariableList [x,y,z,t])

```

First of all, let us solve this system in the sense of Kalkbrener.

```

zeroSetSplit(lp)$T
      5      4      2      3      8      5      3      2      4      2
[{z  - t , t z y  + 2z y - t  + 2t  + t  - t , (t  - t)x - t y - z },
Type: List RegularTriangularSet(Integer,
                                IndexedExponents OrderedVariableList [x,y,z,t],
                                OrderedVariableList [x,y,z,t],
                                NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```

lts := zeroSetSplit(lp,false)$T
      5      4      2      3      8      5      3      2      4      2
[{z  - t , t z y  + 2z y - t  + 2t  + t  - t , (t  - t)x - t y - z },
      3      5      2      3      2
{t  - 1, z  - t, t z y  + 2z y + 1, z x  - t}, {t,z,y,x}]
Type: List RegularTriangularSet(Integer,
                                IndexedExponents OrderedVariableList [x,y,z,t],
                                OrderedVariableList [x,y,z,t],
                                NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [x,y,z,t]))

```

We can see that the first decomposition is a subset of the second.
So how can both be correct ?

Recall first that polynomials from a domain of the category RecursivePolynomialCategory are regarded as univariate polynomials in their main variable. For instance the second polynomial in the first set of each decomposition has main variable y and its initial (its leading coefficient w.r.t. its main variable) is t z.

Now let us explain how to read the second decomposition. Note that the non-constant initials of the first set are $t^4 - t$ and $t z$. Then the solutions described by this first set are the common zeros of its polynomials that do not cancel the polynomials $t^4 - t$ and $ty z$. Now the solutions of the input system lp satisfying these equations are described by the second and the third sets of the decomposition. Thus, in some sense, they can be considered as degenerated solutions.

The solutions given by the first set are called the generic points of the system; they give the general form of the solutions. The first decomposition only provides these generic points. This latter decomposition is useful when they are many degenerated solutions (which is sometimes hard to compute) and when one is only interested in general informations, like the dimension of the input system.

We can get the dimensions of each component of a decomposition as follows.

```
[coHeight(ts) for ts in lts]
[1,0,0]
```

Type: List NonNegativeInteger

Thus the first set has dimension one. Indeed t can take any value, except 0 or any third root of 1, whereas z is completely determined from t , y is given by z and t , and finally x is given by the other three variables. In the second and the third sets of the second decomposition the four variables are completely determined and thus these sets have dimension zero.

We give now the precise specifications of each decomposition. This assume some mathematical knowledge. However, for the non-expert user, the above explanations will be sufficient to understand the other features of the RSEGSET constructor.

The input system lp is decomposed in the sense of Kalkbrener as finitely many regular sets $T_1, \dots, T_s$ such that the radical ideal generated by lp is the intersection of the radicals of the saturated ideals of $T_1, \dots, T_s$. In other words, the affine variety associated with lp is the union of the closures (w.r.t. Zarisky topology) of the regular-zeros sets of $T_1, \dots, T_s$.

N. B. The prime ideals associated with the radical of the saturated ideal of a regular triangular set have all the same dimension; moreover these prime ideals can be given by characteristic sets with the same main variables. Thus a decomposition in the sense of Kalkbrener is unmixed dimensional. Then it can be viewed as a lazy decomposition into prime ideals (some of these prime ideals being merged into unmixed dimensional ideals).

Now we explain the other way of solving by means of regular triangular sets. The input system lp is decomposed in the sense of Lazard as finitely many regular triangular sets $T_1, \dots, T_s$ such that the affine variety associated with lp is the union of the regular-zeros sets of $T_1, \dots, T_s$. Thus a decomposition in the sense of Lazard is also a decomposition in the sense of Kalkbrener; the converse is false as we have seen before.

When the input system has a finite number of solutions, both ways of solving provide similar decompositions as we shall see with this

second example (Caprasse).

Define a polynomial system.

```
f1 := y**2*z+2*x*y*t-2*x-z
      2
      (2t y - 2)x + z y - z
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

f2:=-x**3*z+ 4*x*y**2*z+4*x**2*y*t+2*y**3*t+4*x**2-10*y**2+4*x*z-10*y*t+2
      3      2      2      3      2
      - z x + (4t y + 4)x + (4z y + 4z)x + 2t y - 10y - 10t y + 2
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

f3 := 2*y*z*t+x*t**2-x-2*z
      2
      (t - 1)x + 2t z y - 2z
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

f4:=-x*z**3+4*y*z**2*t+4*x*z*t**2+2*y*t**3+4*x*z+4*z**2-10*y*t- 10*t**2+2
      3      2      2      3      2      2
      (- z + (4t + 4)z)x + (4t z + 2t - 10t)y + 4z - 10t + 2
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

lf := [f1, f2, f3, f4]
      2
      [(2t y - 2)x + z y - z,
      3      2      2      3      2
      - z x + (4t y + 4)x + (4z y + 4z)x + 2t y - 10y - 10t y + 2,
      2
      (t - 1)x + 2t z y - 2z,
      3      2      2      3      2      2
      (- z + (4t + 4)z)x + (4t z + 2t - 10t)y + 4z - 10t + 2]
      Type: List NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])
```

First of all, let us solve this system in the sense of Kalkbrener.

```
zeroSetSplit(lf)$T
      2      8      6      2      3      2
      [{t - 1,z - 16z + 256z - 256,t y - 1,(z - 8z)x - 8z + 16},
      2      2      2
      {3t + 1,z - 7t - 1,y + t,x + z},
      8      6      2      3      2
      {t - 10t + 10t - 1,z,(t - 5t)y - 5t + 1,x},
      2      2
```

```

{t + 3,z - 4,y + t,x - z}]
Type: List RegularTriangularSet(Integer,
    IndexedExponents OrderedVariableList [x,y,z,t],
    OrderedVariableList [x,y,z,t],
    NewSparseMultivariatePolynomial(Integer,
        OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```

lts2 := zeroSetSplit(lf,false)$T
      8      6      2      3      2
[ {t - 10t + 10t - 1,z,(t - 5t)y - 5t + 1,x},
  2      8      6      2      3      2
{t - 1,z - 16z + 256z - 256,t y - 1,(z - 8z)x - 8z + 16},
  2      2      2      2      2
{3t + 1,z - 7t - 1,y + t,x + z}, {t + 3,z - 4,y + t,x - z}]
Type: List RegularTriangularSet(Integer,
    IndexedExponents OrderedVariableList [x,y,z,t],
    OrderedVariableList [x,y,z,t],
    NewSparseMultivariatePolynomial(Integer,
        OrderedVariableList [x,y,z,t]))

```

Up to the ordering of the components, both decompositions are identical.

Let us check that each component has a finite number of solutions.

```

[coHeight(ts) for ts in lts2]
[0,0,0,0]
Type: List NonNegativeInteger

```

Let us count the degrees of each component,

```

degrees := [degree(ts) for ts in lts2]
[8,16,4,4]
Type: List NonNegativeInteger

```

and compute their sum.

```

reduce(+,degrees)
32
Type: PositiveInteger

```

We study now the options of the `zeroSetSplit` operation. As we have seen yet, there is an optional second argument which is a boolean value. If this value is true (this is the default) then the decomposition is computed in the sense of Kalkbrener, otherwise it is computed in the sense of Lazard.

There is a second boolean optional argument that can be used (in that case the first optional argument must be present). This second option allows you to get some information during the computations.

Therefore, we need to understand a little what is going on during the computations. An important feature of the algorithm is that the intermediate computations are managed in some sense like the processes of a Unix system. Indeed, each intermediate computation may generate other intermediate computations and the management of all these computations is a crucial task for the efficiency. Thus any intermediate computation may be suspended, killed or resumed, depending on algebraic considerations that determine priorities for these processes. The goal is of course to go as fast as possible towards the final decomposition which means to avoid as much as possible unnecessary computations.

To follow the computations, one needs to set to true the second argument. Then a lot of numbers and letters are displayed. Between a [and a] one has the state of the processes at a given time. Just after [one can see the number of processes. Then each process is represented by two numbers between < and >. A process consists of a list of polynomial ps and a triangular set ts; its goal is to compute the common zeros of ps that belong to the regular-zeros set of ts. After the processes, the number between pipes gives the total number of polynomials in all the sets ps. Finally, the number between braces gives the number of components of a decomposition that are already computed. This number may decrease.

Let us take a third example (Czapor-Geddes-Wang) to see how this information is displayed.

Define a polynomial system.

```
u : R := 2
2
Type: Integer

q1 := 2*(u-1)**2+ 2*(x-z*x+z**2)+ y**2*(x-1)**2- 2*u*x+ 2*y*t*(1-x)*(x-z)+_
2*u*z*t*(t-y)+ u**2*t**2*(1-2*z)+ 2*u*t**2*(z-x)+ 2*u*t*y*(z-1)+_
2*u*z*x*(y+1)+ (u**2-2*u)*z**2*t**2+ 2*u**2*z**2+ 4*u*(1-u)*z+_
t**2*(z-x)**2}
2      2 2      2      2      2
(y - 2t y + t )x + (- 2y + ((2t + 4)z + 2t)y + (- 2t + 2)z - 4t - 2)x
+
2      2      2      2
y + (- 2t z - 4t)y + (t + 10)z - 8z + 4t + 2
Type: NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [x,y,z,t])

q2 := t*(2*z+1)*(x-z)+ y*(z+2)*(1-x)+ u*(u-2)*t+ u*(1-2*u)*z*t+_
u*y*(x+u-z*x-1)+ u*(u+1)*z**2*t}
(- 3z y + 2t z + t)x + (z + 4)y + 4t z - 7t z
Type: NewSparseMultivariatePolynomial(Integer,
```

```

OrderedVariableList [x,y,z,t])

q3 := -u**2*(z-1)**2+ 2*z*(z-x)-2*(x-1)
      (- 2z - 2)x - 2z + 8z - 2
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

q4 := u**2+4*(z-x**2)+3*y**2*(x-1)**2- 3*t**2*(z-x)**2+_
      3*u**2*t**2*(z-1)**2+u**2*z*(z-2)+6*u*t*y*(z+x+z*x-1)}
      2      2      2      2      2      2
      (3y - 3t - 4)x + (- 6y + (12t z + 12t)y + 6t z)x + 3y + (12t z - 12t)y
+
      2      2      2      2
      (9t + 4)z + (- 24t - 4)z + 12t + 4
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

lq := [q1, q2, q3, q4]
[
      2      2      2
      (y - 2t y + t )x
+
      2      2      2      2      2
      (- 2y + ((2t + 4)z + 2t)y + (- 2t + 2)z - 4t - 2)x + y
+
      2      2      2
      (- 2t z - 4t)y + (t + 10)z - 8z + 4t + 2
,
      2      2      2
      (- 3z y + 2t z + t)x + (z + 4)y + 4t z - 7t z, (- 2z - 2)x - 2z + 8z - 2,
      2      2      2      2      2
      (3y - 3t - 4)x + (- 6y + (12t z + 12t)y + 6t z)x + 3y
+
      2      2      2      2
      (12t z - 12t)y + (9t + 4)z + (- 24t - 4)z + 12t + 4
]
      Type: List NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

```

Let us try the information option. N.B. The timing should be between 1 and 10 minutes, depending on your machine.

```

zeroSetSplit(lq,true,true)$T

```

Between a sequence of processes, thus between a] and a [you can see capital letters W, G, I and lower case letters i, w. Each time a capital letter appears a non-trivial computation has be performed and its result is put in a hash-table. Each time a lower case letter appears a needed result has been found in an hash-table. The use of these hash-tables generally speed up the computations. However, on very large systems, it may happen that these hash-tables become too big to be handle by your AXIOM configuration. Then in these

exceptional cases, you may prefer getting a result (even if it takes a long time) than getting nothing. Hence you need to know how to prevent the RSEGSET constructor from using these hash-tables. In that case you will be using the zeroSetSplit with five arguments. The first one is the input system lp as above. The second one is a boolean value hash? which is true iff you want to use hash-tables. The third one is boolean value clos? which is true iff you want to solve your system in the sense of Kalkbrener, the other way remaining that of Lazard. The fourth argument is boolean value info? which is true iff you want to display information during the computations. The last one is boolean value prep? which is true iff you want to use some heuristics that are performed on the input system before starting the real algorithm. The value of this flag is true when you are using zeroSetSplit with less than five arguments. Note that there is no available signature for zeroSetSplit with four arguments.

We finish this section by some remarks about both ways of solving, in the sense of Kalkbrener or in the sense of Lazard. For problems with a finite number of solutions, there are theoretically equivalent and the resulting decompositions are identical, up to the ordering of the components. However, when solving in the sense of Lazard, the algorithm behaves differently. In that case, it becomes more incremental than in the sense of Kalkbrener. That means the polynomials of the input system are considered one after another whereas in the sense of Kalkbrener the input system is treated more globally.

This makes an important difference in positive dimension. Indeed when solving in the sense of Kalkbrener, the Primeidealkettensatz of Krull is used. That means any regular triangular containing more polynomials than the input system can be deleted. This is not possible when solving in the sense of Lazard. This explains why Kalkbrener's decompositions usually contain less components than those of Lazard. However, it may happen with some examples that the incremental process (that cannot be used when solving in the sense of Kalkbrener) provide a more efficient way of solving than the global one even if the Primeidealkettensatz is used. Thus just try both, with the various options, before concluding that you cannot solve your favorite system with zeroSetSplit. There exist more options at the development level that are not currently available in this public version.

)abbrev domain REGSET RegularTriangularSet
++ Author: Marc Moreno Maza
++ Date Created: 08/25/1998
++ Date Last Updated: 16/12/1998
++ References :
++ [1] M. MORENO MAZA "A new algorithm for computing triangular
++      decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ This domain provides an implementation of regular chains.
++ Moreover, the operation zeroSetSplit is an implementation of a new
++ algorithm for solving polynomial systems by means of regular chains.

RegularTriangularSet(R,E,V,P) : SIG == CODE where
  R : GcdDomain

=====

RewriteRule examples

=====

For example:

```

logrule := rule log(x) + log(y) == log(x*y)
          log(y) + log(x) + %C == log(x y) + %C

f := log(sin(x)) + log(x)
   log(sin(x)) + log(x)

logrule f
   log(x sin(x))

```

Note that you cannot write the simple form of a rule as:

```
rule1 := rule a*x+b == b*x+a
```

as this causes an infinite loop. The pattern is properly matched but the result also properly matches and the pattern is applied again.

domain ROIRC RightOpenIntervalRootCharacterization

The domain `RightOpenIntervalRootCharacterization` is the main code that provides the functionalities of `RealRootCharacterizationCategory` for the case of archimedean fields. Abstract roots are encoded with a left closed right open interval containing the root together with a defining polynomial for the root.

CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like `sqrt(2) + sqrt(2)` you have two new variables which happen to be equal. To avoid this name the expression such as in `s2 := sqrt(2) ; s2 + s2`

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which most natural to you.

LIMITATIONS

The file `reclos.input` show some basic use of the package. This package uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

=====

RomanNumeral Examples

=====

The Roman numeral package was added to Axiom in MCMLXXXVI for use in denoting higher order derivatives.

For example, let f be a symbolic operator.

```
f := operator 'f
f
                                     Type: BasicOperator
```

This is the seventh derivative of f with respect to x.

```
D(f x,x,7)
(vii)
f      (x)
                                     Type: Expression Integer
```

You can have integers printed as Roman numerals by declaring variables to be of type RomanNumeral (abbreviation ROMAN).

```
a := roman(1978 - 1965)
XIII
                                     Type: RomanNumeral
```

This package now has a small but devoted group of followers that claim this domain has shown its efficacy in many other contexts. They claim that Roman numerals are every bit as useful as ordinary integers.

In a sense, they are correct, because Roman numerals form a ring and you can therefore construct polynomials with Roman numeral coefficients, matrices over Roman numerals, etc..

```
x : UTS(ROMAN,'x,0) := x
x
                                     Type: UnivariateTaylorSeries(RomanNumeral,x,0)
```

Was Fibonacci Italian or ROMAN?

```
recip(1 - x - x**2)
```

```

      2      3      4      5      6      7      8
      I + x + II x + III x + V x + VIII x + XIII x + XXI x + XXXIV x
+
      9      10      11
      LV x + LXXXIX x + O(x )
      Type: Union(UnivariateTaylorSeries(RomanNumeral,x,0),...)

```

You can also construct fractions with Roman numeral numerators and denominators, as this matrix Hilberticus illustrates.

```

m : MATRIX FRAC ROMAN
      Type: Void

m := matrix [ [1/(i + j) for i in 1..3] for j in 1..3]
      + I      I      I+
      |-- --- --|
      |II   III  IV|
      |      |      |
      | I    I    I |
      |--- --  - |
      |III  IV   V |
      |      |      |
      | I    I    I |
      |--  -  --|
      +IV   V   VI+
      Type: Matrix Fraction RomanNumeral

```

Note that the inverse of the matrix has integral ROMAN entries.

```

inverse m
      +LXXII  - CCXL   CLXXX +
      |      |      |
      |- CCXL   CM     - DCCXX|
      |      |      |
      +CLXXX  - DCCXX   DC    +
      Type: Union(Matrix Fraction RomanNumeral,...)

```

Unfortunately, the spoiler-sports say that the fun stops when the numbers get big---mostly because the Romans didn't establish conventions about representing very large numbers.

```

y := factorial 10
3628800
      Type: PositiveInteger

```

You work it out!

```

roman y
((((I))))(((((I))))(((((I)))) ((I)))((I)))((I)))((I)))((I)))((I))) ((I))((
(I)) MMMMMMMMDCCC

```

Type: RomanNumeral

Issue the system command `)show RomanNumeral` to display the full list of operations defined by `RomanNumeral`.

```
a := roman(78)
LXXVIII
Type: RomanNumeral
```

```
b := roman(87)
LXXXVII
Type: RomanNumeral
```

```
a + b
CLXV
Type: RomanNumeral
```

```
a * b
MMMMMDCCLXXXVI
Type: RomanNumeral
```

```
b rem a
IX
Type: RomanNumeral
```

ScriptFormulaFormat examples
=====
```

ScriptFormulaFormat provides a coercion from OutputForm} to IBM SCRIPT/VS Mathematical Formula Format. The basic SCRIPT formula format object consists of three parts: a prologue, a formula part and an epilogue. The functions prologue, formula and epilogue extract these parts, respectively. The central parts of the expression go into the formula part. The other parts can be set (setPrologue!, setEpilogue!) so that contain the appropriate tags for printing. For example, the prologue and epilogue might simply contain ":df." and ":edf." so that the formula section will be printed in display math mode.

See Also:
o)show ScriptFormulaFormat

ScriptFormulaFormat (FORMULA)

Exports:

latex	new	prologue	convert	setEpilogue!
setFormula!	setPrologue!	?=?	?~=?	

— domain FORMULA ScriptFormulaFormat —

```

)abbrev domain FORMULA ScriptFormulaFormat
++ Author: Robert S. Sutor
++ Date Created: 1987 through 1990
++ References:
++   SCRIPT Mathematical Formula Formatter User's Guide, SH20-6453,
++   IBM Corporation, Publishing Systems Information Development,
++   Dept. G68, P.O. Box 1900, Boulder, Colorado, USA 80301-9191.
++ Description:
++ \spadtype{ScriptFormulaFormat} provides a coercion from
++ \spadtype{OutputForm} to IBM SCRIPT/VS Mathematical Formula Format.
++ The basic SCRIPT formula format object consists of three parts: a
++ prologue, a formula part and an epilogue. The functions
++ \spadfun{prologue}, \spadfun{formula} and \spadfun{epilogue}
++ extract these parts, respectively. The central parts of the expression
++ go into the formula part. The other parts can be set
++ (\spadfun{setPrologue!}, \spadfun{setEpilogue!}) so that contain the
++ appropriate tags for printing. For example, the prologue and
++ epilogue might simply contain ":df." and ":edf." so that the
++ formula section will be printed in display math mode.

```

```
ScriptFormulaFormat() : SIG == CODE where
```

```

E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String

```

```
SIG ==> SetCategory with
```

```

coerce : E -> %
++ coerce(o) changes o in the standard output format to
++ SCRIPT formula format.

convert : (E,I) -> %
++ convert(o,step) changes o in standard output format to
++ SCRIPT formula format and also adds the given step number.
++ This is useful if you want to create equations with given numbers
++ or have the equation numbers correspond to the interpreter step
++ numbers.

display : (% , I) -> Void
++ display(t,width) outputs the formatted code t so that each
++ line has length less than or equal to \spadvar{width}.

display : % -> Void
++ display(t) outputs the formatted code t so that each
++ line has length less than or equal to the value set by

```

```

++ the system command \spadsyscom{set output length}.

epilogue : % -> L S
++ epilogue(t) extracts the epilogue section of a formatted object t.

formula : % -> L S
++ formula(t) extracts the formula section of a formatted object t.

new : () -> %
++ new() create a new, empty object. Use \spadfun{setPrologue!},
++ \spadfun{setFormula!} and \spadfun{setEpilogue!} to set the
++ various components of this object.

prologue : % -> L S
++ prologue(t) extracts the prologue section of a formatted object t.

setEpilogue! : (% , L S) -> L S
++ setEpilogue!(t,strings) sets the epilogue section of a
++ formatted object t to strings.

setFormula! : (% , L S) -> L S
++ setFormula!(t,strings) sets the formula section of a
++ formatted object t to strings.

setPrologue! : (% , L S) -> L S
++ setPrologue!(t,strings) sets the prologue section of a
++ formatted object t to strings.

=====

Segment examples

=====

The Segment domain provides a generalized interval type.

Segments are created using the .. construct by indicating the (included) end points.

```

s := 3..10
3..10

```

Type: Segment PositiveInteger

The first end point is called the lo and the second is called hi.

```

lo s
3

```

Type: PositiveInteger

These names are used even though the end points might belong to an unordered set.

```
hi s
  10
```

Type: PositiveInteger

In addition to the end points, each segment has an integer "increment". An increment can be specified using the "by" construct.

```
t := 10..3 by -2
    10..3 by - 2
```

Type: Segment PositiveInteger

This part can be obtained using the incr function.

```
incr s
  1
```

Type: PositiveInteger

Unless otherwise specified, the increment is 1.

```
incr t
  - 2
```

Type: Integer

A single value can be converted to a segment with equal end points. This happens if segments and single values are mixed in a list.

```
l := [1..3, 5, 9, 15..11 by -1]
     [1..3,5..5,9..9,15..11 by - 1]
```

Type: List Segment PositiveInteger

If the underlying type is an ordered ring, it is possible to perform additional operations. The expand operation creates a list of points in a segment.

```
expand s
  [3,4,5,6,7,8,9,10]
```

Type: List Integer

If $k > 0$, then `expand(l..h by k)` creates the list `[l, l+k, ..., lN]` where $lN \leq h < lN+k$. If $k < 0$, then $lN \geq h > lN+k$.

```
expand t
  [10,8,6,4]
```

Type: List Integer

It is also possible to expand a list of segments. This is equivalent to appending lists obtained by expanding each segment individually.

```
expand 1
  [1,2,3,5,9,15,14,13,12,11]
                                     Type: List Integer
```

— SegmentBinding.help —

SegmentBinding examples

The SegmentBinding type is used to indicate a range for a named symbol.

First give the symbol, then an = and finally a segment of values.

```

x = a..b
x= a..b

```

Type: SegmentBinding Symbol

This is used to provide a convenient syntax for arguments to certain operations.

```

sum(i**2, i = 0..n)
  3      2
  2n  + 3n  + n
  -----
      6

```

Type: Fraction Polynomial Integer

```

draw(x**2, x = -2..2)

```

```

TwoDimensionalViewport: "x*x"

```

Type: TwoDimensionalViewport

The left-hand side must be of type Symbol but the right-hand side can be a segment over any type.

```

sb := y = 1/2..3/2
      1      3

```

$$y = \frac{(-)}{2} \dots \frac{(-)}{2}$$

Type: SegmentBinding Fraction Integer

The left- and right-hand sides can be obtained using the variable and segment operations.

```
variable(sb)
y
```

Type: Symbol

```
segment(sb)
1 3
(-) .. (-)
2 2
```

Type: Segment Fraction Integer

)abbrev domain SEGBIND SegmentBinding
++ Author: Mark Botch
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain is used to provide the function argument syntax \spad{v=a..b}.
++ This is used, for example, by the top-level \spadfun{draw} functions.

SegmentBinding(S) : SIG == CODE where
  S : Type

SIG ==> Type with

  equation : (Symbol, Segment S) -> %
    ++ equation(v,a..b) creates a segment binding value with variable
    ++ \spad{v} and segment \spad{a..b}. Note that the interpreter parses
    ++ \spad{v=a..b} to this form.

  variable : % -> Symbol
    ++ variable(segb) returns the variable from the left hand side of
    ++ the \spadtype{SegmentBinding}. For example, if \spad{segb} is
    ++ \spad{v=a..b}, then \spad{variable(segb)} returns \spad{v}.

  segment : % -> Segment S
    ++ segment(segb) returns the segment from the right hand side of
    ++ the \spadtype{SegmentBinding}. For example, if \spad{segb} is
    ++ \spad{v=a..b}, then \spad{segment(segb)} returns \spad{a..b}.

  if S has SetCategory then SetCategory

— Set.help —

=====
Set examples
=====

The Set domain allows one to represent explicit finite sets of values.
These are similar to lists, but duplicate elements are not allowed.

Sets can be created by giving a fixed set of values ...

```

s := set [x**2-1, y**2-1, z**2-1]
      2      2      2
      {x  - 1, y  - 1, z  - 1}
                                Type: Set Polynomial Integer

```

or by using a collect form, just as for lists. In either case, the
set is formed from a finite collection of values.

```

t := set [x**i - i+1 for i in 2..10 | prime? i]
      2      3      5      7

```

```

{x2 - 1, x3 - 2, x5 - 4, x7 - 6}
Type: Set Polynomial Integer

```

The basic operations on sets are intersect, union, difference, and symmetricDifference.

```

i := intersect(s,t)
2
{x2 - 1}
Type: Set Polynomial Integer

```

```

u := union(s,t)
2 3 5 7 2 2
{x2 - 1, x3 - 2, x5 - 4, x7 - 6, y2 - 1, z2 - 1}
Type: Set Polynomial Integer

```

The set difference(s,t) contains those members of s which are not in t.

```

difference(s,t)
2 2
{y2 - 1, z2 - 1}
Type: Set Polynomial Integer

```

The set symmetricDifference(s,t) contains those elements which are in s or t but not in both.

```

symmetricDifference(s,t)
3 5 7 2 2
{x3 - 2, x5 - 4, x7 - 6, y2 - 1, z2 - 1}
Type: Set Polynomial Integer

```

Set membership is tested using the member? operation.

```

member?(y, s)
false
Type: Boolean

```

```

member?((y+1)*(y-1), s)
true
Type: Boolean

```

The subset? function determines whether one set is a subset of another.

```

subset?(i, s)
true
Type: Boolean

```

```

subset?(u, s)
false
Type: Boolean

```

When the base type is finite, the absolute complement of a set is defined. This finds the set of all multiplicative generators of `PrimeField 11`---the integers mod 11.

```
gs := set [g for i in 1..11 | primitive?(g := i::PF 11)]
      {2,6,7,8}
```

```
Type: Set PrimeField 11
```

The following values are not generators.

```
complement gs
  {1,3,4,5,9,10,0}
```

Type: Set PrimeField 11

Often the members of a set are computed individually; in addition, values can be inserted or removed from a set over the course of a computation.

There are two ways to do this:

```
a := set [i**2 for i in 1..5]
{1,4,9,16,25}
```

Type: Set PositiveInteger

One is to view a set as a data structure and to apply updating operations.

```
insert!(32, a)
{1,4,9,16,25,32}
```

Type: Set PositiveInteger

```
remove!(25, a)
{1,4,9,16,32}
```

Type: Set PositiveInteger

a

$\{1, 4, 9, 16, 32\}$

Type: Set PositiveInteger

The other way is to view a set as a mathematical entity and to create new sets from old.

```
b := b0 := set [i**2 for i in 1..5]
{1,4,9,16,25}
```

Type: Set PositiveInteger

```
b := union(b, {32})
{1,4,9,16,25,32}
```

Type: Set PositiveInteger

```

b := difference(b, {25})
    {1,4,9,16,32}
                                Type: Set PositiveInteger

b0
    {1,4,9,16,25}
                                Type: Set PositiveInteger

```

— domain SET Set —

```

)abbrev domain SET Set
++ Author: Michael Monagan; revised by Richard Jenks

```

```

++ Date Created: August 87 through August 88
++ Date Last Updated: May 1991
++ Description:
++ A set over a domain D models the usual mathematical notion of a finite set
++ of elements from D.
++ Sets are unordered collections of distinct elements
++ (that is, order and duplication does not matter).
++ The notation \spad{set [a,b,c]} can be used to create
++ a set and the usual operations such as union and intersection are available
++ to form new sets.
++ In our implementation, \Language{} maintains the entries in
++ sorted order. Specifically, the parts function returns the entries
++ as a list in ascending order and
++ the extract operation returns the maximum entry.
++ Given two sets s and t where \spad{#s = m} and \spad{#t = n},
++ the complexity of\br
++ \tab{5}\spad{s = t} is \spad{0(min(n,m))}\br
++ \tab{5}\spad{s < t} is \spad{0(max(n,m))}\br
++ \tab{5}\spad{union(s,t)}, \spad{intersect(s,t)}, \spad{minus(s,t)},\br
++ \tab{10} \spad{symmetricDifference(s,t)} is \spad{0(max(n,m))}\br
++ \tab{5}\spad{member(x,t)} is \spad{0(n log n)}\br
++ \tab{5}\spad{insert(x,t)} and \spad{remove(x,t)} is \spad{0(n)}

++ Author: Manuel Bronstein
++ Date Created: 10 January 1994
++ Date Last Updated: 10 January 1994
++ Description:
++ \spadtype{SetOfMIntegersInOneToN} implements the subsets of M integers
++ in the interval \spad{[1..n]}
  
```

SetOfMIntegersInOneToN(m, n) : SIG == CODE where

```

n : PositiveInteger
m : PositiveInteger
  
```

```

PI ==> PositiveInteger
N ==> NonNegativeInteger
U ==> Union(%, "failed")
  
```

SIG ==> Finite with

```

incrementKthElement : (%, PI) -> U
  
```

```

++ incrementKthElement(S,k) increments the kth element of S,
++ and returns "failed" if the result is not a set of M integers
++ in \spad{1..n} any more.

replaceKthElement : (%, PI, PI) -> U
++ replaceKthElement(S,k,p) replaces the kth element of S by p,
++ and returns "failed" if the result is not a set of M integers
++ in \spad{1..n} any more.

elements : % -> List PI
++ elements(S) returns the list of the elements of S in increasing order.

setOfMinN : List PI -> %
++ setOfMinN([a1,...,am]) returns the set {a1,...,am}.
++ Error if {a1,...,am} is not a set of M integers in \spad{1..n}.

enumerate : () -> Vector %
++ enumerate() returns a vector of all the sets of M integers in
++ \spad{1..n}.

member? : (PI, %) -> Boolean
++ member?(p, s) returns true is p is in s, false otherwise.

delta : (%, PI, PI) -> N
++ delta(S,k,p) returns the number of elements of S which are strictly
++ between p and the kth element of S.

SequentialDifferentialVariable examples

=====

OrderlyDifferentialVariable adds a commonly used sequential ranking to the set of derivatives of an ordered list of differential indeterminates. A sequential ranking is a ranking $<$ of the derivatives with the property that for any derivative v , there are only a finite number of derivatives u with $u < v$. This domain belongs to DifferentialVariableCategory. It defines weight to be just order, and it defines a sequential ranking $<$ on derivatives u by the lexicographic order on the pair $(\text{variable}(u), \text{order}(u))$.

=====

SimpleAlgebraicExtension examples

=====

Algebraic extension of a ring by a single polynomial. Domain which represents simple algebraic extensions of arbitrary rings. The first argument to the domain, R, is the underlying ring, the second argument is a domain of univariate polynomials over K, while the last argument specifies the defining minimal polynomial.

The elements of the domain are canonically represented as polynomials of degree less than that of the minimal polynomial with coefficients in R. The second argument is both the type of the third argument and the underlying representation used by SAE itself.

domain SINT SingleInteger

This type represents finite (machine) precision integers which wrap around at a machine dependent value. However, **SingleInteger** has type **EntireRing** which should have no non-zero divisors. But

$$(2 * 16 : SINT) * 2 = 0$$

on a 32 bit machine. Using **SingleInteger** is a pragmatic efficiency choice. In this condition, Axiom will complain that the result is not of type FIXNUM, which is the Common Lisp type for machine integers.

SingleInteger examples

=====

The SingleInteger domain is intended to provide support in Axiom for machine integer arithmetic. It is generally much faster than (bignum) Integer arithmetic but suffers from a limited range of values. Since Axiom can be implemented on top of various dialects of Lisp, the actual representation of small integers may not correspond exactly to the host machines integer representation.

You can discover the minimum and maximum values in your implementation by using min and max.

```
min()$SingleInteger
- 2147483648
                                     Type: SingleInteger
```

```
max()$SingleInteger
2147483647
                                     Type: SingleInteger
```

To avoid confusion with Integer, which is the default type for integers, you usually need to work with declared variables.

```
a := 1234 :: SingleInteger
1234
                                     Type: SingleInteger
```

or use package calling

```
b := 124$SingleInteger
124
                                     Type: SingleInteger
```

You can add, multiply and subtract SingleInteger objects, and ask for the greatest common divisor (gcd).

```
gcd(a,b)
2
                                     Type: SingleInteger
```

The least common multiple (lcm) is also available.

```
lcm(a,b)
76508
                                     Type: SingleInteger
```

Operations mulmod, addmod, submod, and invmod are similar - they provide arithmetic modulo a given small integer.

Here is $5 * 6 \bmod 13$.

```
mulmod(5,6,13)$SingleInteger
```

```
4
```

```
Type: SingleInteger
```

To reduce a small integer modulo a prime, use `positiveRemainder`.

```
positiveRemainder(37,13)$SingleInteger
```

```
11
```

```
Type: SingleInteger
```

Operations `And`, `Or`, `xor`, and `Not` provide bit level operations on small integers.

```
And(3,4)$SingleInteger
```

```
0
```

```
Type: SingleInteger
```

Use `shift(int,numToShift)` to shift bits, where `i` is shifted left if `numToShift` is positive, right if negative.

```
shift(1,4)$SingleInteger
```

```
16
```

```
Type: SingleInteger
```

```
shift(31,-1)$SingleInteger
```

```
15
```

```
Type: SingleInteger
```

Many other operations are available for small integers, including many of those provided for `Integer`.

)abbrev domain SEM SparseEchelonMatrix
++ Description:
++ \spad{SparseEchelonMatrix(C, D)} implements sparse matrices whose columns
++ are enumerated by the \spadtype{OrderedSet} \spad{C} and whose entries
++ belong to the \spadtype{GcdDomain} \spad{D}. The basic operation of
++ this domain is the computation of an row echelon form. The used algorithm
++ tries to maintain the sparsity and is especially adapted to matrices who
++ are already close to a row echelon form.

```

```

shallowlyMutable
  ++ Matrices may be altered destructively.

finiteAggregate
  ++ Matrices are finite.

coerce : % -> MD
  ++ \spad{coerce(A)} yields the matrix \spad{A} in the usual matrix type.

copy : % -> %
  ++ \spad{copy(A)} returns a copy of the matrix \spad{A}.

ncols : % -> NNI
  ++ \spad{ncols(A)} returns the number of columns of the matrix \spad{A}.

nrows : % -> NNI
  ++ \spad{nrows(A)} returns the number of rows of the matrix \spad{A}.

allIndices : % -> L C
  ++ \spad{allIndices(A)} returns all indices used for enumerating the
  ++ columns of the matrix \spad{A}.

elimZeroCols! : % -> Void
  ++ \spad{elimZeroCols!(A)} removes columns which contain only zeros.
  ++ This effects basically only the value of \spad{allIndices(A)}.

purge! : (% , C-> B) -> Void
  ++ \spad{purge!(A, crit)} eliminates all columns belonging to an index
  ++ \spad{c} such that \spad{crit(c)} yields \spad{true}.

sortedPurge! : (% , C-> B) -> Void
  ++ \spad{sortedPurge!(A, crit)} is like \spad{purge}, however, with the
  ++ additional assumption that \spad{crit} respects the ordering of the
  ++ indices.

new : (L C, I) -> %
  ++ \spad{new(inds, nrows)} generates a new matrix with \spad{nrows}
  ++ rows and columns enumerated by the indices \spad{inds}. The matrix
  ++ is empty, the zero matrix.

elt : (% , I, C) -> D

```

```

++ \spad{elt(A, i, c)} returns the entry of the matrix \spad{A} in row
++ \spad{i} and in the column with index \spad{c}.

setelt! : (% , I, C, D) -> Void
++ \spad{setelt!(A, i, c, d)} sets the entry of the matrix \spad{A} in
++ row \spad{i} and in the column with index \spad{c} to the value
++ \spad{d}.

row : (% , I) -> ROWREC
++ \spad{row(A, i)} returns the \spad{i}-th row of the matrix \spad{A}.

setRow! : (% , I, ROWREC) -> Void
++ \spad{setRow!(A, i, ind, ent)} sets the \spad{i}-th row of the matrix
++ \spad{A} to the value \spad{r}.

setRow! : (% , I, L C, L D) -> Void
++ \spad{setRow!(A, i, ind, ent)} sets the \spad{i}-th row of the matrix
++ \spad{A}. Its indices are \spad{ind}; the entries \spad{ent}.

deleteRow! : (% , I) -> Void
++ \spad{deleteRow(A, i)} deletes the \spad{i}-th row of the matrix
++ \spad{A}.

consRow! : (% , ROWREC) -> Void
++ \spad{consRow!(A, r)} inserts the row \spad{r} at the top of the
++ matrix \spad{A}.

appendRow! : (% , ROWREC) -> Void
++ \spad{appendRow!(A, r)} appends the row \spad{r} at the end of the
++ matrix \spad{A}.

extract : (% , I, I) -> %
++ \spad{extract(A, i1, i2)} extracts the rows \spad{i1} to \spad{i2}
++ and returns them as a new matrix.

rowEchelon : % -> Record(Ech : %, Lt : MD, Pivots : L D, Rank : NNI)
++ \spad{primitiveRowEchelon(A)} computes a row echelon form for the
++ matrix \spad{A}. The algorithm used is fraction-free elimination.
++ It is especially adapted to matrices already close to row echelon
++ form. The transformation matrix, the used pivots and the rank of the
++ matrix are also returned.

if D has GcdDomain then

  setGcdMode : Sy -> Sy
  ++ \spad{setGcdMode(s)} sets a new value for the flag deciding on
  ++ the method used to compute gcd's for lists. Possible values for
  ++ \spad{s} are \spad{iterated} and \spad{random}.

  primitiveRowEchelon : % -> Record(Ech:%, Lt:MFD, Pivots:L D, Rank:NNI)

```

```

    ++ \spad{primitiveRowEchelon(A)} computes a row echelon form for the
    ++ matrix \spad{A}. The algorithm used is fraction-free elimination.
    ++ Every row is made primitive by division by the gcd. The algorithm
    ++ is especially adapted to matrices already close to row echelon
    ++ form. The transformation matrix, the used pivots and the rank of the
    ++ matrix are also returned.

pivot : (%, I) -> Record(Index : C, Entry : D)
    ++ \spad{pivot(A, i)} returns the leading entry of the \spad{i}-th row
    ++ of the matrix \spad{A} together with its index.

pivots : % -> ROWREC
    ++ \spad{pivots(A)} returns all leading entries of the matrix \spad{A}
    ++ together with their indices.

"*" : (MD, %) -> %
    ++ \spad{L*A} implements left multiplication with a usual matrix.

if D has IntegralDomain then

    "*" : (MFD, %) -> %
        ++ \spad{L*A} implements left multiplication with a usual matrix over
        ++ the quotient field of \spad{D}.

join : (%, %) -> %
    ++ \spad{join(A, B)} vertically concats the matrices \spad{A} and
    ++ \spad{B}.

horizJoin : (%, %) -> %
    ++ \spad{horizJoin(A, B)} horizontally concats the matrices \spad{A} and
    ++ \spad{B}. It is assumed that all indices of \spad{B} are smaller than
    ++ those of \spad{A}.

horizSplit : (%, C) -> Record(Left : %, Right : %)
    ++ \spad{horizSplit(A, c)} splits the matrix \spad{A} into two at the
    ++ column given by \spad{c}. The first column of the right matrix is
    ++ enumerated by the first index less or equal to \spad{c}.

```

=====
SparseMultivariateTaylorSeries examples
=====

```

Assume we have three variables which get expressed as sparse multivariate taylor series.

```

xts:=x::TaylorSeries Fraction Integer
yts:=y::TaylorSeries Fraction Integer
zts:=z::TaylorSeries Fraction Integer

```

These will cause traditional routines to expand in series form:

```

t1:=sin(xts)

```

$$x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + 0(11)$$

We can ask for a specific coefficient, in this case, the coefficient of the third power.

```
coefficient(t1,3)
```

$$-\frac{1}{6}x^3$$

And we can get that coefficient, expressed as a monomial.

```
coefficient(t1,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$

In a multivariate version we get a polynomial in x and y

```
t2:=sin(xts + yts)
```

$$\begin{aligned} & (y + x) + \left(-\frac{1}{6}y^3 - \frac{1}{2}xy^2 - \frac{1}{2}x^2y - \frac{1}{6}x^3 \right) \\ & + \left(\frac{1}{120}y^5 + \frac{1}{24}xy^4 + \frac{1}{12}x^2y^3 + \frac{1}{12}x^3y^2 + \frac{1}{24}x^4y + \frac{1}{120}x^5 \right) \\ & + \text{PAREN} \left(-\frac{1}{5040}y^7 - \frac{1}{720}xy^6 - \frac{1}{240}x^2y^5 - \frac{1}{144}x^3y^4 - \frac{1}{144}x^4y^3 - \frac{1}{240}x^5y^2 \right. \\ & \quad \left. - \frac{1}{720}x^6y - \frac{1}{5040}x^7 \right) \\ & + \text{PAREN} \left(\frac{1}{362880}y^9 + \frac{1}{40320}x^8y + \frac{1}{10080}x^7y^2 + \frac{1}{4320}x^6y^3 + \frac{1}{2880}x^5y^4 \right) \end{aligned}$$

$$\begin{aligned}
 &+ \\
 &\quad \frac{1}{2880} x^5 y^4 + \frac{1}{4320} x^6 y^3 + \frac{1}{10080} x^7 y^2 + \frac{1}{40320} x^8 y + \frac{1}{362880} x^9 \\
 &+ \\
 &\quad 0(11)
 \end{aligned}$$

We can ask for the third coefficient which is

```
coefficient(t2,3)
```

$$-\frac{1}{6} y^3 - \frac{1}{2} x y^2 - \frac{1}{2} x^2 y - \frac{1}{6} x^3$$

And we can ask for the third coefficient of that coefficient in x

```
coefficient(t2,monomial(3,x)$IndexedExponents Symbol)
```

$$-\frac{1}{6}$$

And we can convert that result to a polynomial

```
polynomial(t2,5)
```

$$\begin{aligned}
 &\frac{1}{120} y^5 + \frac{1}{24} x y^4 + \left(-\frac{1}{12} x^2 - \frac{1}{6}\right) y^3 + \left(-\frac{1}{12} x^3 - \frac{1}{2} x\right) y^2 + \left(-\frac{1}{24} x^4 - \frac{1}{2} x^2 + 1\right) y \\
 &+ \\
 &\frac{1}{120} x^5 - \frac{1}{6} x^3 + x
 \end{aligned}$$

— domain SMTS SparseMultivariateTaylorSeries —

```

)abbrev domain SMTS SparseMultivariateTaylorSeries
++ Authors: William Burge, Stephen Watt, Clifton Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ This domain provides multivariate Taylor series with variables
++ from an arbitrary ordered set. A Taylor series is represented
++ by a stream of polynomials from the polynomial domain SMP.
++ The nth element of the stream is a form of degree n. SMTS is an
++ internal domain.

```

```

SparseMultivariateTaylorSeries(Coef,Var,SMP) : SIG == CODE where
  Coef : Ring

```

=====

SparseTable examples

=====

The SparseTable domain provides a general purpose table type with default entries.

Here we create a table to save strings under integer keys. The value "Try again!" is returned if no other value has been stored for a key.

```
t: SparseTable(Integer, String, "Try again!") := table()
```

```
table()
```

```
Type: SparseTable(Integer,String,Try again!)
```

Entries can be stored in the table.

```
t.3 := "Number three"
      "Number three"
```

```
Type: String
```

```
t.4 := "Number four"
      "Number four"
```

```
Type: String
```

These values can be retrieved as usual, but if a look up fails the default entry will be returned.

```
t.3
      "Number three"
```

```
Type: String
```

```
t.2
      "Try again!"
```

```
Type: String
```

To see which values are explicitly stored, the keys and entries functions can be used.

```
keys t
      [4,3]
```

```
Type: List Integer
```

```
entries t
      ["Number four","Number three"]
```

```
Type: List String
```

If a specific table representation is required, the `GeneralSparseTable` constructor should be used. The domain `SparseTable(K, E, dflt)` is equivalent to `GeneralSparseTable(K,E,Table(K,E), dflt)`.

=====
SparseUnivariateLaurentSeries examples
=====

```

`SparseUnivariateLaurentSeries` is a domain representing Laurent series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `SparseUnivariateLaurentSeries(Integer,x,3)` represents Laurent series in $(x - 3)$ with integer coefficients.

SparseUnivariatePolynomial examples

=====

This domain represents univariate polynomials over arbitrary (not necessarily commutative) coefficient rings. The variable is unspecified so that the variable displays as ? on output. If it is necessary to specify the variable name, use type UnivariatePolynomial. The representation is sparse in the sense that only non-zero terms are represented. Note that if the coefficient ring is a field, this domain forms a euclidean domain.

)abbrev domain SUP SparseUnivariatePolynomial
++ Author: Dave Barton, Barry Trager
++ Description:
++ This domain represents univariate polynomials over arbitrary
++ (not necessarily commutative) coefficient rings. The variable is
++ unspecified so that the variable displays as \spad{?} on output.
++ If it is necessary to specify the variable name,
++ use type \spadtype{UnivariatePolynomial}. The representation is sparse
++ in the sense that only non-zero terms are represented.
++ Note that if the coefficient ring is a field,
++ this domain forms a euclidean domain.

SparseUnivariatePolynomial(R) : SIG == CODE where

domain SUEXPR SparseUnivariatePolynomialExpressions

This domain is a hack, in some sense. What I'd really like to do - automatically - is to provide all operations supported by the coefficient domain, as long as the polynomials can be retracted to that domain,, as long as they are just constants. I don't see another way to do this, unfortunately.

=====

SparseUnivariatePuisseuxSeries examples

=====

SparseUnivariatePuisseuxSeries is a domain representing Puiseux series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `SparseUnivariatePuisseuxSeries(Integer,x,3)` represents Puiseux series in $(x - 3)$ with Integer coefficients.

=====

SparseUnivariateTaylorSeries examples

=====

SparseUnivariateTaylorSeries is a domain representing Taylor series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `SparseUnivariateTaylorSeries(Integer,x,3)` represents Taylor series in $(x - 3)$ with Integer coefficients.

SplitHomogeneousDirectProduct examples
=====

```

This type represents the finite direct or cartesian product of an underlying ordered component type. The vectors are ordered as if they were split into two blocks. The dim1 parameter specifies the length of the first block. The ordering is lexicographic between the blocks but acts like HomogeneousDirectProduct within each block.

This type is a suitable third argument for
GeneralDistributedMultivariatePolynomial.

=====

SplittingNode examples

=====

This domain exports a modest implementation for the vertices of splitting trees. These vertices are called here splitting nodes. Every of these nodes store 3 informations. The first one is its value, that is the current expression to evaluate. The second one is its condition, that is the hypothesis under which the value has to be evaluated. The last one is its status, that is a boolean flag which is true iff the value is the result of its evaluation under its condition. Two splitting vertices are equal iff they have the sane values and the same conditions (so their status do not matter).

=====

SplittingTree examples

=====

This domain exports a modest implementation of splitting trees. Splitting trees are needed when the evaluation of some quantity under some hypothesis requires to split the hypothesis into sub-cases. For instance by adding some new hypothesis on one hand and its negation on another hand. The computations are terminated is a splitting tree a when status(value(a)) is true. Thus, if for the splitting tree a the flag status(value(a)) is true, then status(value(d)) is true for any subtree d of a. This property of splitting trees is called the termination condition. If no vertex in a splitting tree a is equal to another, a is said to satisfy the no-duplicates condition. The splitting tree a will satisfy this condition if nodes are added to a by mean of splitNodeOf! and if construct is only used to create the root of a with no children.

)abbrev domain SPLTREE SplittingTree
++ Author: Marc Moereno Maza
++ Date Created: 07/05/1996
++ Date Last Updated: 07/19/1996
++ References:
++   M. MORENO MAZA "Calculs de pgcd au-dessus des tours
++   d'extensions simples et resolution des systemes d'equations
++   algebriques" These, Universite P.etM. Curie, Paris, 1997.
++ Description:
++ This domain exports a modest implementation of splitting
++ trees. Splitting trees are needed when the
++ evaluation of some quantity under some hypothesis
++ requires to split the hypothesis into sub-cases.
++ For instance by adding some new hypothesis on one
++ hand and its negation on another hand. The computations
++ are terminated is a splitting tree \axiom{a} when
  
```

```

++ \axiom{status(value(a))} is \axiom{true}. Thus,
++ if for the splitting tree \axiom{a} the flag
++ \axiom{status(value(a))} is \axiom{true}, then
++ \axiom{status(value(d))} is \axiom{true} for any
++ subtree \axiom{d} of \axiom{a}. This property
++ of splitting trees is called the termination
++ condition. If no vertex in a splitting tree \axiom{a}
++ is equal to another, \axiom{a} is said to satisfy
++ the no-duplicates condition. The splitting
++ tree \axiom{a} will satisfy this condition
++ if nodes are added to \axiom{a} by mean of
++ \axiom{splitNodeOf!} and if \axiom{construct}
++ is only used to create the root of \axiom{a}
++ with no children.

SplittingTree(V,C) : SIG == CODE where
  V : Join(SetCategory,Aggregate)

  VTB ==> Record(val:V, tower:C, flag:B)
  S ==> SplittingNode(V,C)
  A ==> Record(root:S,subTrees:List(%))

  SIG ==> RecursiveAggregate(S) with

    shallowlyMutable

    finiteAggregate

    extractSplittingLeaf : % -> Union(%, "failed")
      ++ \axiom{extractSplittingLeaf(a)} returns the left
      ++ most leaf (as a tree) whose status is false
      ++ if any, else "failed" is returned.

    updateStatus! : % -> %
      ++ \axiom{updateStatus!(a)} returns a where the status
      ++ of the vertices are updated to satisfy
      ++ the "termination condition".

    construct : S -> %
      ++ \axiom{construct(s)} creates a splitting tree
      ++ with value (root vertex) given by
      ++ \axiom{s} and no children. Thus, if the
      ++ status of \axiom{s} is false, \axiom{[s]}
      ++ represents the starting point of the
      ++ evaluation \axiom{value(s)} under the

```

```

++ hypothesis \axiom{condition(s)}.

construct : (V,C, List %) -> %
++ \axiom{construct(v,t,la)} creates a splitting tree
++ with value (root vertex) given by
++ \axiom{[v,t]$S} and with \axiom{la} as
++ children list.

construct : (V,C,List S) -> %
++ \axiom{construct(v,t,ls)} creates a splitting tree
++ with value (root vertex) given by
++ \axiom{[v,t]$S} and with children list given by
++ \axiom{[[s]$% for s in ls]}.

construct : (V,C,V,List C) -> %
++ \axiom{construct(v1,t,v2,lt)} creates a splitting tree
++ with value (root vertex) given by
++ \axiom{[v,t]$S} and with children list given by
++ \axiom{[[[v,t]$S]$% for s in ls]}.

conditions : % -> List C
++ \axiom{conditions(a)} returns the list of the conditions
++ of the leaves of a

result : % -> List VT
++ \axiom{result(a)} where \axiom{ls} is the leaves list of \axiom{a}
++ returns \axiom{[[value(s),condition(s)]$VT for s in ls]}
++ if the computations are terminated in \axiom{a} else
++ an error is produced.

nodeOf? : (S,%) -> B
++ \axiom{nodeOf?(s,a)} returns true iff some node of \axiom{a}
++ is equal to \axiom{s}

subNodeOf? : (S,%,(C,C) -> B) -> B
++ \axiom{subNodeOf?(s,a,sub?) } returns true iff for some node
++ \axiom{n} in \axiom{a} we have \axiom{s = n} or
++ \axiom{status(n)} and \axiom{subNode?(s,n,sub?)}.

remove : (S,%) -> %
++ \axiom{remove(s,a)} returns the splitting tree obtained
++ from a by removing every sub-tree \axiom{b} such
++ that \axiom{value(b)} and \axiom{s} have the same
++ value, condition and status.

remove! : (S,%) -> %
++ \axiom{remove!(s,a)} replaces a by remove(s,a)

splitNodeOf! : (%,%,List(S)) -> %
++ \axiom{splitNodeOf!(l,a,ls)} returns \axiom{a} where the children

```

```

++ list of \axiom{l} has been set to
++ \axiom{[[s]$% for s in ls | not nodeOf?(s,a)]}.
++ Thus, if \axiom{l} is not a node of \axiom{a}, this
++ latter splitting tree is unchanged.

splitNodeOf! : (%,% ,List(S),(C,C) -> B) -> %
++ \axiom{splitNodeOf!(l,a,ls,sub?) } returns \axiom{a} where the
++ children list of \axiom{l} has been set to
++ \axiom{[[s]$% for s in ls | not subNodeOf?(s,a,sub?) ]}.
++ Thus, if \axiom{l} is not a node of \axiom{a}, this
++ latter splitting tree is unchanged.

=====

SquareFreeRegularTriangularSet examples

=====

The SquareFreeRegularTriangularSet domain constructor implements square-free regular triangular sets. See the RegularTriangularSet domain constructor for general regular triangular sets. Let T be a regular triangular set consisting of polynomials $t_1, \dots, t_m$ ordered by increasing main variables. The regular triangular set T is square-free if T is empty or if $t_1, \dots, t_{m-1}$ is square-free and if the polynomial t_m is square-free as a univariate polynomial with coefficients in the tower of simple extensions associated with $t_1, \dots, t_{m-1}$.

The main interest of square-free regular triangular sets is that their associated towers of simple extensions are product of fields. Consequently, the saturated ideal of a square-free regular triangular set is radical. This property simplifies some of the operations related to regular triangular sets. However, building square-free regular triangular sets is generally more expensive than building general regular triangular sets.

As the RegularTriangularSet domain constructor, the SquareFreeRegularTriangularSet domain constructor also implements a method for solving polynomial systems by means of regular triangular sets. This is in fact the same method with some adaptations to take

into account the fact that the computed regular chains are square-free. Note that it is also possible to pass from a decomposition into general regular triangular sets to a decomposition into square-free regular triangular sets. This conversion is used internally by the `LazardSetSolvingPackage` package constructor.

N.B. When solving polynomial systems with the `SquareFreeRegularTriangularSet` domain constructor or the `LazardSetSolvingPackage` package constructor, decompositions have no redundant components. See also `LexTriangularPackage` and `ZeroDimensionalSolvePackage` for the case of algebraic systems with a finite number of (complex) solutions.

We shall explain now how to use the constructor `SquareFreeRegularTriangularSet`.

This constructor takes four arguments. The first one, `R`, is the coefficient ring of the polynomials; it must belong to the category `GcdDomain`. The second one, `E`, is the exponent monoid of the polynomials; it must belong to the category `OrderedAbelianMonoidSup`. The third one, `V`, is the ordered set of variables; it must belong to the category `OrderedSet`. The last one is the polynomial ring; it must belong to the category `RecursivePolynomialCategory(R,E,V)`. The abbreviation for `SquareFreeRegularTriangularSet` is `SREGSET`.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

Let us illustrate the use of this constructor with one example (Donati-Traverso). Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
OrderedVariableList [x,y,z,t]
Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
```

Type: Domain

Define the polynomial ring.

```
P := NSMP(R, V)
  NewSparseMultivariatePolynomial(Integer, OrderedVariableList [x,y,z,t])
                                     Type: Domain
```

Let the variables be polynomial.

```
x: P := 'x
  x
      Type: NewSparseMultivariatePolynomial(Integer,
                                             OrderedVariableList [x,y,z,t])
```

```
y: P := 'y
  y
      Type: NewSparseMultivariatePolynomial(Integer,
                                             OrderedVariableList [x,y,z,t])
```

```
z: P := 'z
  z
      Type: NewSparseMultivariatePolynomial(Integer,
                                             OrderedVariableList [x,y,z,t])
```

```
t: P := 't
  t
      Type: NewSparseMultivariatePolynomial(Integer,
                                             OrderedVariableList [x,y,z,t])
```

Now call the SquareFreeRegularTriangularSet domain constructor.

```
ST := SREGSET(R,E,V,P)
SquareFreeRegularTriangularSet(Integer, IndexedExponents OrderedVariableList [
x,y,z,t], OrderedVariableList [x,y,z,t], NewSparseMultivariatePolynomial(Integer,
r, OrderedVariableList [x,y,z,t]))
                                     Type: Domain
```

Define a polynomial system.

```
p1 := x ** 31 - x ** 6 - x - y
      31      6
      x  - x  - x - y
      Type: NewSparseMultivariatePolynomial(Integer,
                                             OrderedVariableList [x,y,z,t])
```

```
p2 := x ** 8 - z
      8
      x  - z
      Type: NewSparseMultivariatePolynomial(Integer,
```

```

OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
      10
      x  - t
      Type: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

lp := [p1, p2, p3]
      31      6      8      10
      [x  - x  - x - y, x  - z, x  - t]
      Type: List NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])

```

First of all, let us solve this system in the sense of Kalkbrener.

```

zeroSetSplit(lp)$ST
      5      4      2      3      8      5      3      2      4      2
      [{z  - t , t z y  + 2z y - t  + 2t  + t  - t , (t  - t)x - t y - z },
      Type: List SquareFreeRegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))

```

And now in the sense of Lazard (or Wu and other authors).

```

zeroSetSplit(lp,false)$ST
      5      4      2      3      8      5      3      2      4      2
      [{z  - t , t z y  + 2z y - t  + 2t  + t  - t , (t  - t)x - t y - z },
      3      5      2      2
      {t  - 1, z  - t, t y + z , z x  - t}, {t,z,y,x}]
      Type: List SquareFreeRegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))

```

Now to see the difference with the RegularTriangularSet domain constructor, we define:

```

T := REGSET(R,E,V,P)
RegularTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t],O
rderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedV
ariableList [x,y,z,t]))
      Type: Domain

```

and compute:

```

lts := zeroSetSplit(lp,false)$T

```

Then we compute:

```

toseSquareFreePart(pol,tower)$pack
      2      3      5
[[val= t y + z ,tower= {t  - 1,z  - t}]]
Type: List Record(val: NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]),
tower: RegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])))

```

=====

SquareMatrix examples

=====

The top level matrix type in Axiom is Matrix, which provides basic arithmetic and linear algebra functions. However, since the matrices can be of any size it is not true that any pair can be added or multiplied. Thus Matrix has little algebraic structure.

Sometimes you want to use matrices as coefficients for polynomials or in other algebraic contexts. In this case, SquareMatrix should be used. The domain SquareMatrix(n,R) gives the ring of n by n square matrices over R.

Since SquareMatrix is not normally exposed at the top level, you must expose it before it can be used.

```
)set expose add constructor SquareMatrix
```

Once SQMATRIX has been exposed, values can be created using the squareMatrix function.

```

m := squareMatrix [ [1,-%i],[%i,4] ]
+1 - %i+
|      |
+%i  4 +
                                     Type: SquareMatrix(2,Complex Integer)

```

The usual arithmetic operations are available.

```

m*m - m
+ 1 - 4%i+
|      |
+4%i  13 +
                                     Type: SquareMatrix(2,Complex Integer)

```

Square matrices can be used where ring elements are required.

For example, here is a matrix with matrix entries.

```
mm := squareMatrix [ [m, 1], [1-m, m**2] ]
++1  - %i+      +1  0+  +
||      |      |  |  |
|+%i  4  +      +0  1+  |
|      |      |  |  |
|+ 0    %i +  + 2  - 5%i+|
||      |  |      ||
++- %i  - 3+  +5%i  17  ++
                                     Type: SquareMatrix(2,SquareMatrix(2,Complex Integer))
```

Or you can construct a polynomial with square matrix coefficients.

```
p := (x + m)**2
      2  + 2  - 2%i+      + 2  - 5%i+
x  + |      |x + |      |
      +2%i  8  +      +5%i  17  +
                                     Type: Polynomial SquareMatrix(2,Complex Integer)
```

This value can be converted to a square matrix with polynomial coefficients.

```
p::SquareMatrix(2, ?)
+ 2      +
|x  + 2x + 2  - 2%i x - 5%i|
|      |
|      2      |
+2%i x + 5%i  x  + 8x + 17 +
                                     Type: SquareMatrix(2,Polynomial Complex Integer)
```

— domain SQMATRIX SquareMatrix —

```
)abbrev domain SQMATRIX SquareMatrix
++ Author: Grabmeier, Gschnitzer, Williamson
++ Date Created: 1987
++ Date Last Updated: July 1990
++ Description:
++ \spadtype{SquareMatrix} is a matrix domain of square matrices, where the
++ number of rows (= number of columns) is a parameter of the type.
```

```
SquareMatrix(ndim,R) : SIG == CODE where
  ndim : NonNegativeInteger
  R : Ring
```

```

Row ==> DirectProduct(ndim,R)
Col ==> DirectProduct(ndim,R)
MATLIN ==> MatrixLinearAlgebraFunctions(R,Row,Col,$)

SIG ==> Join(SquareMatrixCategory(ndim,R,Row,Col),_
             CoercibleTo Matrix R) with

transpose : $ -> $
  ++ \spad{transpose(m)} returns the transpose of the matrix m.

squareMatrix : Matrix R -> $
  ++ \spad{squareMatrix(m)} converts a matrix of type \spadtype{Matrix}
  ++ to a matrix of type \spadtype{SquareMatrix}.

coerce : $ -> Matrix R
  ++ \spad{coerce(m)} converts a matrix of type \spadtype{SquareMatrix}
  ++ to a matrix of type \spadtype{Matrix}.

if R has commutative("*") then central
  ++ the elements of the Ring R, viewed as diagonal matrices, commute
  ++ with all matrices and, indeed, are the only matrices which commute
  ++ with all matrices.

if R has commutative("*") and R has unitsKnown then unitsKnown
  ++ the invertible matrices are simply the matrices whose determinants
  ++ are units in the Ring R.

if R has ConvertibleTo InputForm then ConvertibleTo InputForm

— Stack.help —

Stack examples

A Stack object is represented as a list ordered by last-in, first-out. It operates like a pile of books, where the "next" book is the one on the top of the pile.

Here we create a stack of integers from a list. Notice that the order in the list is the order in the stack.

```
a:Stack INT:= stack [1,2,3,4,5]
      [1,2,3,4,5]
```

We can remove the top of the stack using pop!:

```
pop! a
      1
```

Notice that the use of pop! is destructive (destructive operations in Axiom usually end with ! to indicate that the underlying data structure is changed).

```
a
      [2,3,4,5]
```

The extract! operation is another name for the pop! operation and has the same effect. This operation treats the stack as a BagAggregate:

```
extract! a
      2
```

and you can see that it also has destructively modified the stack:

```
a
      [3,4,5]
```

Next we push a new element on top of the stack:

```
push!(9,a)
      9
```

Again, the push! operation is destructive so the stack is changed:

```
a
      [9,2,3,4,5]
```

Another name for push! is insert!, which treats the stack as a BagAggregate:

```
insert!(8,a)
      [8,9,3,4,5]
```

and it modifies the stack:

```
a
      [8,9,3,4,5]
```

The inspect function returns the top of the stack without modification, viewed as a BagAggregate:

```
inspect a
8
```

The `empty?` operation returns true only if there are no element on the stack, otherwise it returns false:

```
empty? a
false
```

The `top` operation returns the top of stack without modification, viewed as a Stack:

```
top a
8
```

The `depth` operation returns the number of elements on the stack:

```
depth a
5
```

which is the same as the `# (length)` operation:

```
#a
5
```

The `less?` predicate will compare the stack length to an integer:

```
less?(a,9)
true
```

The `more?` predicate will compare the stack length to an integer:

```
more?(a,9)
false
```

The `size?` operation will compare the stack length to an integer:

```
size?(a,#a)
true
```

and since the last computation must always be true we try:

```
size?(a,9)
false
```

The `parts` function will return the stack as a list of its elements:

```
parts a
[8,9,3,4,5]
```

If we have a `BagAggregate` of elements we can use it to construct a stack. Notice that the elements are pushed in reverse order:

```
bag([1,2,3,4,5])$Stack(INT)
[5,4,3,2,1]
```

The `empty` function will construct an empty stack of a given type:

```
b:=empty()$(Stack INT)
[]
```

and the `empty?` predicate allows us to find out if a stack is empty:

```
empty? b
true
```

The `sample` function returns a sample, empty stack:

```
sample()$Stack(INT)
[]
```

We can copy a stack and it does not share storage so subsequent modifications of the original stack will not affect the copy:

```
c:=copy a
[8,9,3,4,5]
```

The `eq?` function is only true if the lists are the same reference, so even though `c` is a copy of `a`, they are not the same:

```
eq?(a,c)
false
```

However, `a` clearly shares a reference with itself:

```
eq?(a,a)
true
```

But we can compare `a` and `c` for equality:

```
(a=c)@Boolean
true
```

and clearly `a` is equal to itself:

```
(a=a)@Boolean
true
```

and since `a` and `c` are equal, they are clearly NOT not-equal:

```
a~=c
false
```

We can use the `any?` function to see if a predicate is true for any element:

```
any?(x+>(x=4),a)
true
```

or false for every element:

```
any?(x+>(x=11),a)
false
```

We can use the `every?` function to check every element satisfies a predicate:

```
every?(x+>(x=11),a)
false
```

We can count the elements that are equal to an argument of this type:

```
count(4,a)
1
```

or we can count against a boolean function:

```
count(x+>(x>2),a)
5
```

You can also map a function over every element, returning a new stack:

```
map(x+>x+10,a)
[18,19,13,14,15]
```

Notice that the original stack is unchanged:

```
a
[8,9,3,4,5]
```

You can use `map!` to map a function over every element and change the original stack since `map!` is destructive:

```
map!(x+>x+10,a)
[18,19,13,14,15]
```

Notice that the original stack has been changed:

```
a
[18,19,13,14,15]
```

The `member` function can also get the element of the stack as a list:

```
members a
  [18,19,13,14,15]
```

and using `member?` we can test if the stack holds a given element:

```
member?(14,a)
  true
```

=====

StochasticDifferential examples

=====

A basic implementation of StochasticDifferential(R) using the associated domain BasicStochasticDifferential in the underlying representation as sparse multivariate polynomials. The domain is a module over Expression(R), and is a ring without identity (AXIOM term is "Rng"). Note that separate instances, for example using R=Integer and R=Float, have different hidden structure (multiplication and drift tables).

```
dt := introduce!(t,dt)
dt
```

```

RetractableTo(BSD)

alterQuadVar! : (BSD,BSD,%) -> Union(%, "failed")
++ alterQuadVar! adds multiplication formula for a
++ pair of stochastic differentials to a private table.
++ Failure occurs if
++ (a) either of first or second arguments is not basic
++ (b) third argument is not exactly of first degree

alterDrift! : (BSD,%) -> Union(%, "failed")
++ alterDrift! adds drift formula for a
++ stochastic differential to a private table.
++ Failure occurs if
++ (a) first arguments is not basic
++ (b) second argument is not exactly of first degree

drift : % -> %
++ drift(dx) returns the drift of \axiom{dx}

freeOf? : (%,BSD) -> Boolean
++ freeOf?(sd,dX) checks whether \axiom{dX} occurs in
++ \axiom{sd} as a module element

coefficient : (%,BSD) -> ER
++ coefficient(sd,dX) returns the coefficient of \axiom{dX}
++ in the stochastic differential \axiom{sd}

listSD : (%) -> List BSD
++ listSD(dx) returns a list of all \axiom{BSD} involved
++ in the generation of \axiom{dx} as a module element

equation : (%,R) -> Union(Equation %, "failed")
++ equation(dx,0) allows RHS of Equation % to be zero
equation : (R,%) -> Union(Equation %, "failed")
++ equation(0,dx) allows LHS of Equation % to be zero

copyDrift : () -> Table(%,%)
++ copyDrift returns private table of drifts
++ of basic stochastic differentials for inspection

copyQuadVar : () -> Table(%,%)
++ copyQuadVar returns private multiplication table
++ of basic stochastic differentials for inspection

```

```

"/" : (% , ER) -> %
  ++ dx/y divides the stochastic differential dx
  ++ by the previsible function y.

"*)" : (% , PI) -> %
  ++ dx**n is dx multiplied by itself n times.

"^" : (% , PI) -> %
  ++ dx^n is dx multiplied by itself n times.

statusIto : () -> OF
  ++ statusIto() displays the current state of \axiom{setBSD},
  ++ \axiom{tableDrift}, and \axiom{tableQuadVar}. Question
  ++ marks are printed instead of undefined entries
  ++
  ++X dt:=introduce!(t,dt)
  ++X dX:=introduce!(X,dX)
  ++X dY:=introduce!(Y,dY)
  ++X copyBSD()
  ++X copyIto()
  ++X copyhQuadVar()
  ++X statusIto()

uncorrelated? : (% ,%) -> Boolean
  ++ uncorrelated?(dx,dy) checks whether its two arguments
  ++ have zero quadratic co-variation.

uncorrelated? : (List % ,List %) -> Boolean
  ++ uncorrelated?(l1,l2) checks whether its two arguments
  ++ are lists of stochastic differentials of zero inter-list
  ++ quadratic co-variation.

uncorrelated? : (List List %) -> Boolean
  ++ uncorrelated?(l1) checks whether its argument is a list
  ++ of lists of stochastic differentials of zero inter-list
  ++ quadratic co-variation.

=====
Stream examples
=====

A Stream object is represented as a list whose last element contains

the wherewithal to create the next element, should it ever be required.

Let `ints` be the infinite stream of non-negative integers.

```
ints := [i for i in 0..]
       [0,1,2,3,4,5,6,7,8,9,...]
                                     Type: Stream NonNegativeInteger
```

By default, ten stream elements are calculated. This number may be changed to something else by the system command
`)set streams calculate`

More generally, you can construct a stream by specifying its initial value and a function which, when given an element, creates the next element.

```
f : List INT -> List INT
                                     Type: Void

f x == [x.1 + x.2, x.1]
                                     Type: Void

fibs := [i.2 for i in [generate(f,[1,1])]]
       [1,1,2,3,5,8,13,21,34,55,...]
                                     Type: Stream Integer
```

You can create the stream of odd non-negative integers by either filtering them from the integers, or by evaluating an expression for each integer.

```
[i for i in ints | odd? i]
       [1,3,5,7,9,11,13,15,17,19,...]
                                     Type: Stream NonNegativeInteger

odds := [2*i+1 for i in ints]
       [1,3,5,7,9,11,13,15,17,19,...]
                                     Type: Stream NonNegativeInteger
```

You can accumulate the initial segments of a stream using the `scan` operation.

```
scan(0,+,odds)
       [1,4,9,16,25,36,49,64,81,100,...]
                                     Type: Stream NonNegativeInteger
```

The corresponding elements of two or more streams can be combined in this way.

```
[i*j for i in ints for j in odds]
       [0,3,10,21,36,55,78,105,136,171,...]
                                     Type: Stream NonNegativeInteger

map(*,ints,odds)
       [0,3,10,21,36,55,78,105,136,171,...]
```

Type: Stream NonNegativeInteger

Many operations similar to those applicable to lists are available for streams.

```
first ints
0
```

Type: NonNegativeInteger

```
rest ints
[1,2,3,4,5,6,7,8,9,10,...]
```

Type: Stream NonNegativeInteger

```
fibs 20
6765
```

Type: PositiveInteger

— domain **STREAM Stream** —

```

)abbrev domain STREAM Stream
++ Implementation of streams via lazy evaluation
++ Authors: Burge, Watt; updated by Clifton J. Williamson
++ Date Created: July 1986
++ Date Last Updated: 30 March 1990
++ Description:
++ A stream is an implementation of an infinite sequence using
++ a list of terms that have been computed and a function closure
++ to compute additional terms when needed.

```

```

Stream(S) : SIG == CODE where
  S : Type

  B ==> Boolean
  OUT ==> OutputForm
  I ==> Integer
  L ==> List
  NNI ==> NonNegativeInteger
  U ==> UniversalSegment I

  SIG ==> LazyStreamAggregate(S) with

    shallowlyMutable
      ++ one may destructively alter a stream by assigning new
      ++ values to its entries.

    coerce : L S -> %
      ++ coerce(l) converts a list l to a stream.
      ++
      ++X m:=[1,2,3,4,5,6,7,8,9,10,11,12]
      ++X coerce(m)@Stream(Integer)
      ++X m::Stream(Integer)

    repeating : L S -> %
      ++ repeating(l) is a repeating stream whose period is the list l.
      ++
      ++X m:=repeating([-1,0,1,2,3])

    if S has SetCategory then

      repeating? : (L S,%) -> B
        ++ repeating?(l,s) returns true if a stream s is periodic
        ++ with period l, and false otherwise.
        ++
        ++X m:=[1,2,3]
        ++X n:=repeating(m)
        ++X repeating?(m,n)

      findCycle : (NNI,%) -> Record(cycle?: B, prefix: NNI, period: NNI)
        ++ findCycle(n,st) determines if st is periodic within n.
        ++
        ++X m:=[1,2,3]
        ++X n:=repeating(m)
        ++X findCycle(3,n)
        ++X findCycle(2,n)

    delay : ((() -> %) -> %
      ++ delay(f) creates a stream with a lazy evaluation defined by
      ++ function f.

```

```

++ Caution: This function can only be called in compiled code.

cons : (S,%) -> %
++ cons(a,s) returns a stream whose \spad{first} is \spad{a}
++ and whose \spad{rest} is s.
++ Note: \spad{cons(a,s) = concat(a,s)}.
++
++X m:=[1,2,3]
++X n:=repeating(m)
++X cons(4,n)

if S has SetCategory then

output : (I, %) -> Void
++ output(n,st) computes and displays the first n entries
++ of st.
++
++X m:=[1,2,3]
++X n:=repeating(m)
++X output(5,n)

showAllElements : % -> OUT
++ showAllElements(s) creates an output form which displays all
++ computed elements.
++
++X m:=[1,2,3,4,5,6,7,8,9,10,11,12]
++X n:=m::Stream(PositiveInteger)
++X showAllElements n

showAll? : () -> B
++ showAll?() returns true if all computed entries of streams
++ will be displayed.
--!! this should be a function of one argument

setrest_! : (% ,I,%) -> %
++ setrest!(x,n,y) sets rest(x,n) to y. The function will expand
++ cycles if necessary.
++
++X p:=[i for i in 1..]
++X q:=[i for i in 9..]
++X setrest!(p,4,q)
++X p

generate : ((() -> S) -> %
++ generate(f) creates an infinite stream all of whose elements are
++ equal to \spad{f()}.
++ Note: \spad{generate(f) = [f(),f(),f(),...]}
++
++X f():Integer == 1
++X generate(f)

```

```

generate : (S -> S,S) -> %
++ generate(f,x) creates an infinite stream whose first element is
++ x and whose nth element (\spad{n > 1}) is f applied to the previous
++ element. Note: \spad{generate(f,x) = [x,f(x),f(f(x)),...]}.
++
++X f(x:Integer):Integer == x+10
++X generate(f,10)

filterWhile : (S -> Boolean,%) -> %
++ filterWhile(p,s) returns \spad{[x0,x1,...,x(n-1)]} where
++ \spad{s = [x0,x1,x2,...]} and
++ n is the smallest index such that \spad{p(xn) = false}.
++
++X m:=[i for i in 1..]
++X f(x:PositiveInteger):Boolean == x < 5
++X filterWhile(f,m)

filterUntil : (S -> Boolean,%) -> %
++ filterUntil(p,s) returns \spad{[x0,x1,...,x(n)]} where
++ \spad{s = [x0,x1,x2,...]} and
++ n is the smallest index such that \spad{p(xn) = true}.
++
++X m:=[i for i in 1..]
++X f(x:PositiveInteger):Boolean == x < 5
++X filterUntil(f,m)

— String.help —

=====

String examples

=====

The type String provides character strings. Character strings provide all the operations for a one-dimensional array of characters, plus additional operations for manipulating text.

String values can be created using double quotes.

```

hello := "Hello, I'm AXIOM!"
      "Hello, I'm AXIOM!"
                                Type: String

```

Note, however, that double quotes and underscores must be preceded by an extra underscore.

```

said := "Jane said, \"Look!\_"
      "Jane said, \"Look!\_"
                                Type: String

```

```

saw := "She saw exactly one underscore: \_\_"
      "She saw exactly one underscore: \_\_"
                                Type: String

```

It is also possible to use new to create a string of any size filled with a given character. Since there are many new functions it is necessary to indicate the desired type.

```

gasp: String := new(32, char "x")

```

```

"xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx"
                                Type: String

```

The length of a string is given by #.

```

#gasp
32
                                Type: PositiveInteger

```

Indexing operations allow characters to be extracted or replaced in strings. For any string *s*, indices lie in the range 1..*s*.

```

hello.2
e
                                Type: Character

```

Indexing is really just the application of a string to a subscript, so any application syntax works.

```

hello 2
e
                                Type: Character

```

```

hello(2)
e
                                Type: Character

```

If it is important not to modify a given string, it should be copied before any updating operations are used.

```

hullo := copy hello
"Hello, I'm AXIOM!"
                                Type: String

```

```

hullo.2 := char "u"; [hello, hullo]
["Hello, I'm AXIOM!","Hullo, I'm AXIOM!"]
                                Type: List String

```

Operations are provided to split and join strings. The concat operation allows several strings to be joined together.

```

saw := concat ["alpha","---","omega"]
"alpha---omega"
                                Type: String

```

There is a version of concat that works with two strings.

```

concat("hello ","goodbye")
"hello goodbye"
                                Type: String

```

Juxtaposition can also be used to concatenate strings.

```
"This " "is " "several " "strings " "concatenated."
  "This is several strings concatenated."
                                Type: String
```

Substrings are obtained by giving an index range.

```
hello(1..5)
  "Hello"
                                Type: String
```

```
hello(8..)
  "I'm AXIOM!"
                                Type: String
```

A string can be split into several substrings by giving a separation character or character class.

```
split(hello, char " ")
  ["Hello","I'm","AXIOM!"]
                                Type: List String
```

```
other := complement alphanumeric();
                                Type: CharacterClass
```

```
split(said saw, other)
  ["alpha","omega"]
                                Type: List String
```

Unwanted characters can be trimmed from the beginning or end of a string using the operations `trim`, `leftTrim` and `rightTrim`.

```
trim("## ++ relax ++ ##", char "#")
  " ++ relax ++ "
                                Type: String
```

Each of these functions takes a string and a second argument to specify the characters to be discarded.

```
trim("## ++ relax ++ ##", other)
  "relax"
                                Type: String
```

The second argument can be given either as a single character or as a character class.

```
leftTrim("## ++ relax ++ ##", other)
  "relax ++ ##"
```

Type: String

```
rightTrim("## ++ relax ++ ##", other)
"## ++ relax"
```

Type: String

Strings can be changed to upper case or lower case using the operations `upperCase` and `lowerCase`.

```
upperCase hello
"HELLO, I'M AXIOM!"
```

Type: String

The versions with the exclamation mark change the original string, while the others produce a copy.

```
lowerCase hello
"hello, i'm axiom!"
```

Type: String

Some basic string matching is provided. The function `prefix?` tests whether one string is an initial prefix of another.

```
prefix?("He", "Hello")
true
```

Type: Boolean

```
prefix?("Her", "Hello")
false
```

Type: Boolean

A similar function, `suffix?`, tests for suffixes.

```
suffix?("", "Hello")
true
```

Type: Boolean

```
suffix?("LO", "Hello")
false
```

Type: Boolean

The function `substring?` tests for a substring given a starting position.

```
substring?("ll", "Hello", 3)
true
```

Type: Boolean

```
substring?("ll", "Hello", 4)
false
```

Type: Boolean

A number of position functions locate things in strings. If the first argument to position is a string, then position(s,t,i) finds the location of s as a substring of t starting the search at position i.

```
n := position("nd", "underground", 1)
2
Type: PositiveInteger
```

```
n := position("nd", "underground", n+1)
10
Type: PositiveInteger
```

If s is not found, then 0 is returned (minIndex(s)-1 in IndexedString).

```
n := position("nd", "underground", n+1)
0
Type: NonNegativeInteger
```

To search for a specific character or a member of a character class, a different first argument is used.

```
position(char "d", "underground", 1)
3
Type: PositiveInteger
```

```
position(hexDigit(), "underground", 1)
3
Type: PositiveInteger
```

StringTable examples

This domain provides a table type in which the keys are known to be strings so special techniques can be used. Other than performance, the type `StringTable(S)` should behave exactly the same way as `Table(String, S)`.

This creates a new table whose keys are strings.

```
t: StringTable(Integer) := table()
  table()
                                Type: StringTable Integer
```

The value associated with each string key is the number of characters in the string.

```
for s in split("My name is Ian Watt.",char " ")
  repeat
    t.s := #s
                                Type: Void
```

```
for key in keys t repeat output [key, t.key]
["Watt.",5]
["Ian",3]
["is",2]
["name",4]
["My",2]
                                Type: Void
```

—————

domain SUBSPACE SubSpace

The first argument *n* is the dimension of the subSpace

The SubSpace domain is implemented as a tree. The root of the tree is the only node in which the field *dataList* - which points to a list of points over the ring, *R* - is defined. The children of the root are the top level components of the SubSpace (in 2D, these would be separate curves; in 3D, these would be separate surfaces).

The *pt* field is only defined in the leaves.

By way of example, consider a three dimensional subspace with two components - a three by three grid and a sphere. The internal representation of this subspace is a tree with a depth of three.

The root holds a list of all the points used in the subspace (so, if the grid and the sphere share points, the shared points would not be represented redundantly but would be referenced by index).

The root, in this case, has two children - the first points to the grid component and the second to the sphere component. The grid child has four children of its own - a 3x3 grid has 4 endpoints - and each of these point to a list of four points. To see it another way, the grid (child of the root) holds a list of line components which, when placed one above the next, forms a grid. Each of these line components is a list of points.

Points could be explicitly added to subspaces at any level. A path could be given as an argument to the `addPoint()` function. It is a list of `NonNegativeIntegers` and refers, in order, to the *n*-th child of the current node. For example,

```
addPoint(s,[2,3],p)
```

would add the point *p* to the subspace *s* by going to the second child of the root and then the third child of that node. If the path does extend to the full depth of the tree, nodes are automatically added so that the tree is of constant depth down any path. By not specifying the full path, new components could be added - for example, for *s* from `SubSpace(3,Float)`

```
addPoint(s,[],p)
```

would create a new child to the root (a new component in *N*-space) and extend a path to a leaf of depth 3 that points to the data held in *p*. The subspace *s* would now have a new component which has one child which, in turn, has one child (the leaf). The new component is then a point.

merge : (%,%) -> %
  ++ merge(s1,s2) the subspaces s1 and s2 into a single subspace.

merge : List % -> %
  ++ merge(ls) a list of subspaces, ls, into one subspace.

separate : % -> List %
  ++ separate(s) makes each of the components of the \spadtype{SubSpace},
  ++ s, into a list of separate and distinct subspaces and returns
  ++ the list.

addPoint : (%,List NNI,POINT) -> %
  ++ addPoint(s,li,p) adds the 4 dimensional point, p, to the 3
  ++ dimensional subspace, s. The list of non negative integers, li,
  ++ dictates the path to follow, or, to look at it another way,
  ++ points to the component in which the point is to be added. It's
  ++ length should range from 0 to \spad{n - 1} where n is the dimension
  ++ of the subspace. If the length is \spad{n - 1}, then a specific
  ++ lowest level component is being referenced. If it is less than
  ++ \spad{n - 1}, then some higher level component (0 indicates top
  ++ level component) is being referenced and a component of that level
  ++ with the desired point is created. The subspace s is returned
  ++ with the additional point.

addPoint2 : (%,POINT) -> %
  ++ addPoint2(s,p) adds the 4 dimensional point, p, to the 3
  ++ dimensional subspace, s.
  ++ The subspace s is returned with the additional point.

addPointLast : (%,%,POINT, NNI) -> %
  ++ addPointLast(s,s2,li,p) adds the 4 dimensional point, p, to the 3
  ++ dimensional subspace, s. s2 point to the end of the subspace
  ++ s. n is the path in the s2 component.
  ++ The subspace s is returned with the additional point.

modifyPoint : (%,List NNI,POINT) -> %
  ++ modifyPoint(s,li,p) replaces an existing point in the 3 dimensional
  ++ subspace, s, with the 4 dimensional point, p. The list of non
  ++ negative integers, li, dictates the path to follow, or, to look at
  ++ it another way, points to the component in which the existing point
  ++ is to be modified. An error message occurs if s is empty, otherwise
  ++ the subspace s is returned with the point modification.

addPoint : (%,List NNI,NNI) -> %
  ++ addPoint(s,li,i) adds the 4 dimensional point indicated by the
  ++ index location, i, to the 3 dimensional subspace, s. The list of
  ++ non negative integers, li, dictates the path to follow, or, to
  ++ look at it another way, points to the component in which the point
  ++ is to be added. It's length should range from 0 to \spad{n - 1}

```

```

++ where n is the dimension of the subspace. If the length is
++ \spad{n - 1}, then a specific lowest level component is being
++ referenced. If it is less than \spad{n - 1}, then some higher
++ level component (0 indicates top level component) is being
++ referenced and a component of that level with the desired point
++ is created. The subspace s is returned with the additional point.

modifyPoint : (%,List NNI,NNI) -> %
++ modifyPoint(s,li,i) replaces an existing point in the 3 dimensional
++ subspace, s, with the 4 dimensional point indicated by the index
++ location, i. The list of non negative integers, li, dictates
++ the path to follow, or, to look at it another way, points to the
++ component in which the existing point is to be modified. An error
++ message occurs if s is empty, otherwise the subspace s is returned
++ with the point modification.

addPoint : (%,POINT) -> NNI
++ addPoint(s,p) adds the point, p, to the 3 dimensional subspace, s,
++ and returns the new total number of points in s.

modifyPoint : (%,NNI,POINT) -> %
++ modifyPoint(s,ind,p) modifies the point referenced by the index
++ location, ind, by replacing it with the point, p in the 3 dimensional
++ subspace, s. An error message occurs if s is empty, otherwise the
++ subspace s is returned with the point modification.

closeComponent : (%,List NNI,B) -> %
++ closeComponent(s,li,b) sets the property of the component in the
++ 3 dimensional subspace, s, to be closed if b is true, or open if
++ b is false. The list of non negative integers, li, dictates the
++ path to follow, or, to look at it another way, points to the
++ component whose closed property is to be set. The subspace, s,
++ is returned with the component property modification.

defineProperty : (%,List NNI,PROP) -> %
++ defineProperty(s,li,p) defines the component property in the
++ 3 dimensional subspace, s, to be that of p, where p is of the
++ domain \spadtype{SubSpaceComponentProperty}. The list of non
++ negative integers, li, dictates the path to follow, or, to look
++ at it another way, points to the component whose property is
++ being defined. The subspace, s, is returned with the component
++ property definition.

traverse : (%,List NNI) -> %
++ traverse(s,li) follows the branch list of the 3 dimensional
++ subspace, s, along the path dictated by the list of non negative
++ integers, li, which points to the component which has been
++ traversed to. The subspace, s, is returned, where s is now
++ the subspace pointed to by li.

```

```

extractPoint : % -> POINT
  ++ extractPoint(s) returns the point which is given by the current
  ++ index location into the point data field of the 3 dimensional
  ++ subspace s.

extractIndex : % -> NNI
  ++ extractIndex(s) returns a non negative integer which is the current
  ++ index of the 3 dimensional subspace s.

extractClosed : % -> B
  ++ extractClosed(s) returns the \spadtype{Boolean} value of the closed
  ++ property for the indicated 3 dimensional subspace s. If the
  ++ property is closed, \spad{True} is returned, otherwise \spad{False}
  ++ is returned.

extractProperty : % -> PROP
  ++ extractProperty(s) returns the property of domain
  ++ \spadtype{SubSpaceComponentProperty} of the indicated 3 dimensional
  ++ subspace s.

level : % -> NNI
  ++ level(s) returns a non negative integer which is the current
  ++ level field of the indicated 3 dimensional subspace s.

parent : % -> %
  ++ parent(s) returns the subspace which is the parent of the indicated
  ++ 3 dimensional subspace s. If s is the top level subspace an error
  ++ message is returned.

pointData : % -> L POINT
  ++ pointData(s) returns the list of points from the point data field
  ++ of the 3 dimensional subspace s.

— Symbol.help —

Symbol examples

Symbols are one of the basic types manipulated by Axiom. The Symbol domain provides ways to create symbols of many varieties.

The simplest way to create a symbol is to "single quote" an identifier.

```
X: Symbol := 'x
```

```
x
```

```
Type: Symbol
```

This gives the symbol even if x has been assigned a value. If x has not been assigned a value, then it is possible to omit the quote.

```
XX: Symbol := x
```

```
x
```

```
Type: Symbol
```

Declarations must be used when working with symbols, because otherwise the interpreter tries to place values in a more specialized type Variable.

```
A := 'a
```

```
a
```

```
Type: Variable a
```

```
B := b
```

```
b
```

```
Type: Variable b
```

The normal way of entering polynomials uses this fact.

```
x**2 + 1
```

```
2
```

```
x + 1
```

```
Type: Polynomial Integer
```

Another convenient way to create symbols is to convert a string. This is useful when the name is to be constructed by a program.

```
"Hello"::Symbol
```

```
Hello
```

```
Type: Symbol
```

Sometimes it is necessary to generate new unique symbols, for example, to name constants of integration. The expression new() generates a symbol starting with %.

```
new()$Symbol
```

```
%A
```

```
Type: Symbol
```

Successive calls to new produce different symbols.

```
new()$Symbol
```

```
%B
```

```
Type: Symbol
```

The expression new("s") produces a symbol starting with %s.

```
new("xyz")$Symbol
%xyz0
```

Type: Symbol

A symbol can be adorned in various ways. The most basic thing is applying a symbol to a list of subscripts.

```
X[i,j]
  x
  i,j
```

Type: Symbol

Somewhat less pretty is to attach subscripts, superscripts or arguments.

```
U := subscript(u, [1,2,1,2])
  u
  1,2,1,2
```

Type: Symbol

```
V := superscript(v, [n])
  n
  v
```

Type: Symbol

```
P := argscript(p, [t])
  p(t)
```

Type: Symbol

It is possible to test whether a symbol has scripts using the scripted? test.

```
scripted? U
true
```

Type: Boolean

```
scripted? X
false
```

Type: Boolean

If a symbol is not scripted, then it may be converted to a string.

```
string X
"x"
```

Type: String

The basic parts can always be extracted using the name and scripts operations.

```
name U
u
```

Type: Symbol

```

scripts U
[sub= [1,2,1,2],sup= [],presup= [],presub= [],args= []]
Type: Record(sub: List OutputForm,
             sup: List OutputForm,
             presup: List OutputForm,
             presub: List OutputForm,
             args: List OutputForm)

```

```

name X
x
Type: Symbol

```

```

scripts X
[sub= [],sup= [],presup= [],presub= [],args= []]
Type: Record(sub: List OutputForm,
             sup: List OutputForm,
             presup: List OutputForm,
             presub: List OutputForm,
             args: List OutputForm)

```

The most general form is obtained using the script operation. This operation takes an argument which is a list containing, in this order, lists of subscripts, superscripts, presubscripts, presubscripts and arguments to a symbol.

```

M := script(Mammoth, [ [i,j],[k,l],[0,1],[2],[u,v,w] ])
      0,1      k,l
      Mammoth (u,v,w)
      2      i,j
Type: Symbol

```

```

scripts M
[sub= [i,j],sup= [k,l],presup= [0,1],presub= [2],args= [u,v,w]]
Type: Record(sub: List OutputForm,
             sup: List OutputForm,
             presup: List OutputForm,
             presub: List OutputForm,
             args: List OutputForm)

```

If trailing lists of scripts are omitted, they are assumed to be empty.

```

N := script(Nut, [ [i,j],[k,l],[0,1] ])
      0,1      k,l
      Nut
      i,j
Type: Symbol

```

```

scripts N
[sub= [i,j],sup= [k,l],presup= [0,1],presub= [],args= []]

```

```

Type: Record(sub: List OutputForm,
             sup: List OutputForm,
             presup: List OutputForm,
             presub: List OutputForm,
             args: List OutputForm)

```

— domain SYMTAB SymbolTable —

```

)abbrev domain SYMTAB SymbolTable
++ Author: Mike Dewar
++ Date Created:  October 1992
++ Date Last Updated: 12 July 1994
++ Description:
++ Create and manipulate a symbol table for generated FORTRAN code
  
```

SymbolTable() : SIG == CODE where

```

T  ==> Union(S:Symbol,P:Polynomial Integer)
TL1 ==> List T
TU  ==> Union(name:Symbol,bounds:TL1)
TL  ==> List TU
SEX ==> SExpression
  
```

```

OFORM ==> OutputForm
L ==> List
FSTU ==> Union(fst:FortranScalarType,void:"void")

SIG ==> CoercibleTo OutputForm with

coerce : $ -> Table(Symbol,FortranType)
  ++ coerce(x) returns a table view of x

empty : () -> $
  ++ empty() returns a new, empty symbol table

declare! : (L Symbol,FortranType,$) -> FortranType
  ++ declare!(l,t,tab) creates new entrys in tab, declaring each of l
  ++ to be of type t

declare! : (Symbol,FortranType,$) -> FortranType
  ++ declare!(u,t,tab) creates a new entry in tab, declaring u to be of
  ++ type t

fortranTypeOf : (Symbol,$) -> FortranType
  ++ fortranTypeOf(u,tab) returns the type of u in tab

parametersOf : $ -> L Symbol
  ++ parametersOf(tab) returns a list of all the symbols declared in tab

typeList : (FortranScalarType,$) -> TL
  ++ typeList(t,tab) returns a list of all the objects of type t in tab

externalList : $ -> L Symbol
  ++ externalList(tab) returns a list of all the external symbols in tab

typeLists : $ -> L TL
  ++ typeLists(tab) returns a list of lists of types of objects in tab

newTypeLists : $ -> SEX
  ++ newTypeLists(x) is not documented

printTypes : $ -> Void
  ++ printTypes(tab) produces FORTRAN type declarations from tab, on the
  ++ current FORTRAN output stream

symbolTable: L Record(key:Symbol,entry:FortranType) -> $
  ++ symbolTable(l) creates a symbol table from the elements of l.

=====

Table examples

=====

The Table constructor provides a general structure for associative storage. This type provides hash tables in which data objects can be saved according to keys of any type. For a given table, specific types must be chosen for the keys and entries.

In this example the keys to the table are polynomials with integer coefficients. The entries in the table are strings.

```

t: Table(Polynomial Integer, String) := table()
table()
                                     Type: Table(Polynomial Integer,String)

```

To save an entry in the table, the setelt operation is used. This can be called directly, giving the table a key and an entry.

```

setelt(t, x**2 - 1, "Easy to factor")
"Easy to factor"
                                     Type: String

```

Alternatively, you can use assignment syntax.

```

t(x**3 + 1) := "Harder to factor"
"Harder to factor"
                                     Type: String

```

```

t(x) := "The easiest to factor"
"The easiest to factor"
                                     Type: String

```

Entries are retrieved from the table by calling the `elt` operation.

```
elt(t, x)
  "The easiest to factor"
                                     Type: String
```

This operation is called when a table is "applied" to a key using this or the following syntax.

```
t.x
  "The easiest to factor"
                                     Type: String
```

```
t x
  "The easiest to factor"
                                     Type: String
```

Parentheses are used only for grouping. They are needed if the key is an infix expression.

```
t.(x**2 - 1)
  "Easy to factor"
                                     Type: String
```

Note that the `elt` operation is used only when the key is known to be in the table, otherwise an error is generated.

```
t (x**3 + 1)
  "Harder to factor"
                                     Type: String
```

You can get a list of all the keys to a table using the `keys` operation.

```
keys t
      3      2
  [x,x + 1,x - 1]
                                     Type: List Polynomial Integer
```

If you wish to test whether a key is in a table, the `search` operation is used. This operation returns either an entry or "failed".

```
search(x, t)
  "The easiest to factor"
                                     Type: Union(String,...)
```

```
search(x**2, t)
  "failed"
                                     Type: Union("failed",...)
```

The return type is a union so the success of the search can be tested

using case.

```
search(x**2, t) case "failed"
  true
                                     Type: Boolean
```

The remove operation is used to delete values from a table.

```
remove!(x**2-1, t)
  "Easy to factor"
                                     Type: Union(String,...)
```

If an entry exists under the key, then it is returned. Otherwise remove returns "failed".

```
remove!(x-1, t)
  "failed"
                                     Type: Union("failed",...)
```

The number of key-entry pairs can be found using the # operation.

```
#t
  2
                                     Type: PositiveInteger
```

Just as keys returns a list of keys to the table, a list of all the entries can be obtained using the members operation.

```
members t
(17) ["The easiest to factor","Harder to factor"]
                                     Type: List String
```

A number of useful operations take functions and map them on to the table to compute the result. Here we count the entries which have "Hard" as a prefix.

```
count(s: String +-> prefix?("Hard", s), t)
  1
                                     Type: PositiveInteger
```

Other table types are provided to support various needs.

- o AssociationList gives a list with a table view. This allows new entries to be appended onto the front of the list to cover up old entries. This is useful when table entries need to be stacked or when frequent list traversals are required.
- o EqTable gives tables in which keys are considered equal only when they are in fact the same instance of a structure.
- o StringTable should be used when the keys are known to be strings.
- o SparseTable provides tables with default entries, so lookup never fails. The GeneralSparseTable constructor can be used to make any table type

behave this way.

- o KeyedAccessFile allows values to be saved in a file, accessed as a table.

— domain TS TaylorSeries —

```
)abbrev domain TS TaylorSeries
++ Authors: Burge, Watt, Williamson
++ Date Created: 15 August 1988
++ Date Last Updated: 18 May 1991
++ Description:
++ \spadtype{TaylorSeries} is a general multivariate Taylor series domain
++ over the ring Coef and with variables of type Symbol.
```

```
TaylorSeries(Coef) : SIG == CODE where
  Coef : Ring
```

```
  L ==> List
  NNI ==> NonNegativeInteger
  SMP ==> Polynomial Coef
  StS ==> Stream SMP
```

```
SIG ==> MultivariateTaylorSeriesCategory(Coef,Symbol) with
```

```
  coefficient : (%,NNI) -> SMP
  ++\spad{coefficient(s, n)} gives the terms of total degree n.
```

```
  coerce : Symbol -> %
  ++\spad{coerce(s)} converts a variable to a Taylor series
```

```
  coerce : SMP -> %
  ++\spad{coerce(s)} regroups terms of s by total degree
  ++ and forms a series.
```

```
if Coef has Algebra Fraction Integer then
```

```
  integrate : (%,Symbol,Coef) -> %
```

```

++\spad{integrate(s,v,c)} is the integral of s with respect
++ to v and having c as the constant of integration.

fintegrate : (() -> %,Symbol,Coef) -> %
++\spad{fintegrate(f,v,c)} is the integral of \spad{f()} with respect
++ to v and having c as the constant of integration.
++ The evaluation of \spad{f()} is delayed.

CODE ==> SparseMultivariateTaylorSeries(Coef,Symbol,SMP) add

Rep := StS -- Below we use the fact that Rep of PS is Stream SMP.

polynomial(s,n) ==
sum : SMP := 0
for i in 0..n while not empty? s repeat
  sum := sum + first s
  s:= rst s
sum

domain TEX TexFormat

product(product(i*j,i=a..b),j=c..d) fix

The expression prints properly in ascii text but the tex output is incorrect. Originally the input

```
product(product(i*j,i=a..b),j=c..d)
```

prints as

$$(1) \quad PI2(j = c, d, PI2(i = a, b, i j))$$

but now says: The problem is in [[src/algebra/tex.spad.pamphlet]] in the list of constants. The code used to read

```
plexOps      : L S := ["SIGMA","SIGMA2","PI","INTSIGN","INDEFINTEGRAL"]$(L S)
plexPrecs    : L I := [ 700, 800,      700,      700]$(L I)
```

it now reads:

— **product(product(i*j,i=a..b),j=c..d) fix** —

```
plexOps      : L S := ["SIGMA","SIGMA2","PI","PI2","INTSIGN","INDEFINTEGRAL"]$(L S)
plexPrecs    : L I := [ 700, 800,      700, 800 , 700,      700]$(L I)
```

in addition we need to add a line defining [[PI2]] in [[formatPlex]]:

— **define PI2** —

```
op = "PI2"      => "\prod"
```

— **TexFormat.input** —

```
)set break resume
)sys rm -f TexFormat.output
)spool TexFormat.output
)set message test on
```

```
)set message auto off
)clear all

=====

TexFormat examples

=====

You can ask Axiom to show latex output. In particular, this can be used for complex output.

(1/2)::TEX

["\$\$", "\frac{1}{2} ", "\$\$"]

(1/(x+5))::TEX

["\$\$", "\frac{1}{x+5} ", "\$\$"]

((x+3)/(y-5))::TEX

["\$\$", "\frac{x+3}{y-5} ", "\$\$"]

We can change the fraction display so it is horizontal:

)set output fraction horizontal

(1/2)::TEX

["\$\$", "SLASH ", "\left(", "{1, \: 2} ", "\right)", "\$\$"]

(1/(x+5))::TEX

```

["$$","SLASH ","\left(","{1, \: {x+5}} ","\right)","$$"]

((x+3)/(y-5))::TEX

["$$","SLASH ","\left(","{{x+3}, \: {y -5}} ","\right)","$$"]

```

— domain **TEX** **TexFormat** —

```

)abbrev domain TEX TexFormat
++ Author: Robert S. Sutor
++ Date Created: 1987 through 1992
++ Description:
++ \spadtype{TexFormat} provides a coercion from \spadtype{OutputForm} to
++ \TeX{} format. The particular dialect of \TeX{} used is \LaTeX{}.
++ The basic object consists of three parts: a prologue, a
++ tex part and an epilogue. The functions \spadfun{prologue},
++ \spadfun{tex} and \spadfun{epilogue} extract these parts,
++ respectively. The main guts of the expression go into the tex part.
++ The other parts can be set (\spadfun{setPrologue!},
++ \spadfun{setEpilogue!}) so that contain the appropriate tags for

```

++ printing. For example, the prologue and epilogue might simply
 ++ contain ‘‘\verb+[+’’ and ‘‘\verb+[+’’, respectively, so that
 ++ the TeX section will be printed in LaTeX display math mode.

TexFormat() : SIG == CODE where

```
E ==> OutputForm
I ==> Integer
L ==> List
S ==> String
US ==> UniversalSegment(Integer)
```

SIG ==> SetCategory with

```
coerce : E -> $
  ++ coerce(o) changes o in the standard output format to TeX
  ++ format.

convert : (E,I) -> $
  ++ convert(o,step) changes o in standard output format to
  ++ TeX format and also adds the given step number. This is useful
  ++ if you want to create equations with given numbers or have the
  ++ equation numbers correspond to the interpreter step numbers.

convert : (E,I,E) -> $
  ++ convert(o,step,type) changes o in standard output format to
  ++ TeX format and also adds the given step number and type. This
  ++ is useful if you want to create equations with given numbers
  ++ or have the equation numbers correspond to the interpreter step
  ++ numbers.

display : ($, I) -> Void
  ++ display(t,width) outputs the TeX formatted code t so that each
  ++ line has length less than or equal to \spadvar{width}.

display : $ -> Void
  ++ display(t) outputs the TeX formatted code t so that each
  ++ line has length less than or equal to the value set by
  ++ the system command \spadsyscom{set output length}.

epilogue : $ -> L S
  ++ epilogue(t) extracts the epilogue section of a TeX form t.

tex : $ -> L S
  ++ tex(t) extracts the TeX section of a TeX form t.

new : () -> $
  ++ new() create a new, empty object. Use \spadfun{setPrologue!},
  ++ \spadfun{setTex!} and \spadfun{setEpilogue!} to set the various
  ++ components of this object.
```

```

prologue : $ -> L S
  ++ prologue(t) extracts the prologue section of a TeX form t.

setEpilogue! : ($, L S) -> L S
  ++ setEpilogue!(t,strings) sets the epilogue section of a TeX form t
  ++ to strings.

setTex! : ($, L S) -> L S
  ++ setTex!(t,strings) sets the TeX section of a TeX form t to strings.

setPrologue! : ($, L S) -> L S
  ++ setPrologue!(t,strings) sets the prologue section of a TeX form t
  ++ to strings.

=====

TextFile examples

=====

The domain TextFile allows Axiom to read and write character data and exchange text with other programs. This type behaves in Axiom much like a File of strings, with additional operations to cause new lines. We give an example of how to produce an upper case copy of a file.

This is the file from which we read the text.

```

f1: TextFile := open("/etc/group", "input")
"/etc/group"
Type: TextFile

```

This is the file to which we write the text.

```

f2: TextFile := open("/tmp/MOTD", "output")
"MOTD"
Type: TextFile

```

Entire lines are handled using the readLine and writeLine operations.

```

l := readLine! f1
"root:x:0:root"
Type: String

```

```

writeLine!(f2, upperCase l)
"ROOT:X:0:ROOT"
Type: String

```

Use the endOfFile? operation to check if you have reached the end of the file.

```

while not endOfFile? f1 repeat
  s := readLine! f1
  writeLine!(f2, upperCase s)
Type: Void

```

The file `f1` is exhausted and should be closed.

```
close! f1
  "/etc/group"
                                     Type: TextFile
```

It is sometimes useful to write lines a bit at a time. The write operation allows this.

```
write!(f2, "-The-")
  "-The-"
                                     Type: String
```

```
write!(f2, "-End-")
  "-End-"
                                     Type: String
```

This ends the line. This is done in a machine-dependent manner.

```
writeLine! f2
  ""
                                     Type: String
```

```
close! f2
  "MOTD"
                                     Type: TextFile
```

Finally, clean up.

```
)system rm /tmp/MOTD
```

— domain TEXTFILE TextFile —

```

)abbrev domain TEXTFILE TextFile
++ Author: Stephen M. Watt
++ Date Created: 1985
++ Date Last Updated: June 4, 1991
++ Description:
++ This domain provides an implementation of text files. Text is stored
++ in these files using the native character set of the computer.

```

```

TextFile() : SIG == CODE where

```

```

  StreamName ==> Union(FileName, "console")

```

```

  SIG ==> FileCategory(FileName, String) with

```

```

  writeLine_! : (%, String) -> String
    ++ writeLine!(f,s) writes the contents of the string s
    ++ and finishes the current line in the file f.
    ++ The value of s is returned.

```

```

  writeLine_! : % -> String
    ++ writeLine!(f) finishes the current line in the file f.
    ++ An empty string is returned. The call \spad{writeLine!(f)} is

```

```

++ equivalent to \spad{writeLine!(f,"")}.

readLine_! : % -> String
++ readLine!(f) returns a string of the contents of a line from
++ the file f.

readLineIfCan_! : % -> Union(String, "failed")
++ readLineIfCan!(f) returns a string of the contents of a line from
++ file f, if possible. If f is not readable or if it is
++ positioned at the end of file, then \spad{"failed"} is returned.

readIfCan_! : % -> Union(String, "failed")
++ readIfCan!(f) returns a string of the contents of a line from
++ file f, if possible. If f is not readable or if it is
++ positioned at the end of file, then \spad{"failed"} is returned.

endOfFile? : % -> Boolean
++ endOfFile?(f) tests whether the file f is positioned after the
++ end of all text. If the file is open for output, then
++ this test is always true.

viewThetaDefault : () -> F
  ++ viewThetaDefault() returns the current default longitudinal
  ++ view angle in radians.

viewThetaDefault : F -> F
  ++ viewThetaDefault(t) sets the current default longitudinal
  ++ view angle in radians to the value t and returns t.

viewPhiDefault : () -> F

```

```

++ viewPhiDefault() returns the current default latitudinal
++ view angle in radians.

viewPhiDefault : F -> F
++ viewPhiDefault(p) sets the current default latitudinal
++ view angle in radians to the value p and returns p.

viewZoomDefault : () -> F
++ viewZoomDefault() returns the current default graph scaling
++ value.

viewZoomDefault : F -> F
++ viewZoomDefault(s) sets the current default graph scaling
++ value to s and returns s.

viewDeltaXDefault : () -> F
++ viewDeltaXDefault() returns the current default horizontal
++ offset from the center of the viewport window.

viewDeltaXDefault : F -> F
++ viewDeltaXDefault(dx) sets the current default horizontal
++ offset from the center of the viewport window to be \spad{dx}
++ and returns \spad{dx}.

viewDeltaYDefault : () -> F
++ viewDeltaYDefault() returns the current default vertical
++ offset from the center of the viewport window.

viewDeltaYDefault : F -> F
++ viewDeltaYDefault(dy) sets the current default vertical
++ offset from the center of the viewport window to be \spad{dy}
++ and returns \spad{dy}.

viewport3D : () -> %
++ viewport3D() returns an undefined three-dimensional viewport
++ of the domain \spadtype{ThreeDimensionalViewport} whose
++ contents are empty.

makeViewport3D : % -> %
++ makeViewport3D(v) takes the given three-dimensional viewport,
++ v, of the domain \spadtype{ThreeDimensionalViewport} and
++ displays a viewport window on the screen which contains
++ the contents of v.

makeViewport3D : (SPACE3,S) -> %
++ makeViewport3D(sp,s) takes the given space, \spad{sp} which is
++ of the domain \spadtype{ThreeSpace} and displays a viewport
++ window on the screen which contains the contents of \spad{sp},
++ and whose title is given by s.

```

```

makeViewport3D : (SPACE3,L DROP) -> %
++ makeViewport3D(sp,lopt) takes the given space, \spad{sp} which is
++ of the domain \spadtype{ThreeSpace} and displays a viewport
++ window on the screen which contains the contents of \spad{sp},
++ and whose draw options are indicated by the list \spad{lopt}, which
++ is a list of options from the domain \spad{DrawOption}.

subspace : % -> SPACE3
++ subspace(v) returns the contents of the viewport v, which is
++ of the domain \spadtype{ThreeDimensionalViewport}, as a subspace
++ of the domain \spad{ThreeSpace}.

subspace : (% ,SPACE3) -> %
++ subspace(v,sp) places the contents of the viewport v, which is
++ of the domain \spadtype{ThreeDimensionalViewport}, in the subspace
++ \spad{sp}, which is of the domain \spad{ThreeSpace}.

modifyPointData : (% ,NNI,POINT) -> Void
++ modifyPointData(v,ind,pt) takes the viewport, v, which is of the
++ domain \spadtype{ThreeDimensionalViewport}, and places the data
++ point, \spad{pt} into the list of points database of v at the index
++ location given by \spad{ind}.

options : % -> L DROP
++ options(v) takes the viewport, v, which is of the domain
++ \spadtype{ThreeDimensionalViewport} and returns a list of all
++ the draw options from the domain \spad{DrawOption} which are
++ being used by v.

options : (% ,L DROP) -> %
++ options(v,lopt) takes the viewport, v, which is of the domain
++ \spadtype{ThreeDimensionalViewport} and sets the draw options
++ being used by v to those indicated in the list, \spad{lopt},
++ which is a list of options from the domain \spad{DrawOption}.

move : (% ,NNI,NNI) -> Void
++ move(v,x,y) displays the three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, with the upper
++ left-hand corner of the viewport window at the screen
++ coordinate position x, y.

resize : (% ,PI,PI) -> Void
++ resize(v,w,h) displays the three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, with a width
++ of w and a height of h, keeping the upper left-hand corner
++ position unchanged.

title : (% ,S) -> Void
++ title(v,s) changes the title which is shown in the three-dimensional
++ viewport window, v of domain \spadtype{ThreeDimensionalViewport}.

```

```

dimensions : (% ,NNI,NNI,PI,PI) -> Void
++ dimensions(v,x,y,width,height) sets the position of the
++ upper left-hand corner of the three-dimensional viewport, v,
++ which is of domain \spadtype{ThreeDimensionalViewport}, to
++ the window coordinate x, y, and sets the dimensions of the
++ window to that of \spad{width}, \spad{height}. The new
++ dimensions are not displayed until the function
++ \spadfun{makeViewport3D} is executed again for v.

viewpoint : (% ,F,F,F,F,F) -> Void
++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
++ to \spad{th} radians, the latitudinal view angle to \spad{phi}
++ radians, the scale factor to \spad{s}, the horizontal viewport
++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.

viewpoint : (%) -> V
++ viewpoint(v) returns the current viewpoint setting of the given
++ viewport, v. This function is useful in the situation where the
++ user has created a viewport, proceeded to interact with it via
++ the control panel and desires to save the values of the viewpoint
++ as the default settings for another viewport to be created using
++ the system.

viewpoint : (% ,V) -> Void
++ viewpoint(v,viewpt) sets the viewpoint for the viewport. The
++ viewport record consists of the latitudal and longitudinal angles,
++ the zoom factor, the x,y and z scales, and the x and y displacements.

viewpoint : (% ,I,I,F,F,F) -> Void
++ viewpoint(v,th,phi,s,dx,dy) sets the longitudinal view angle
++ to \spad{th} degrees, the latitudinal view angle to \spad{phi}
++ degrees, the scale factor to \spad{s}, the horizontal viewport
++ offset to \spad{dx}, and the vertical viewport offset to \spad{dy}
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.

viewpoint : (% ,F,F) -> Void
++ viewpoint(v,th,phi) sets the longitudinal view angle to \spad{th}
++ radians and the latitudinal view angle to \spad{phi} radians
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new viewpoint position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.

```

```

viewpoint : (%,F,F,F) -> Void
++ viewpoint(v,rotx,roty,rotz) sets the rotation about the x-axis
++ to be \spad{rotx} radians, sets the rotation about the y-axis
++ to be \spad{roty} radians, and sets the rotation about the z-axis
++ to be \spad{rotz} radians, for the viewport v, which is of the
++ domain \spadtype{ThreeDimensionalViewport} and displays v with
++ the new view position.

controlPanel : (%,S) -> Void
++ controlPanel(v,s) displays the control panel of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or hides
++ the control panel if s is "off".

axes : (%,S) -> Void
++ axes(v,s) displays the axes of the given three-dimensional
++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport},
++ if s is "on", or does not display the axes if s is "off".

diagonals : (%,S) -> Void
++ diagonals(v,s) displays the diagonals of the polygon outline
++ showing a triangularized surface instead of a quadrilateral
++ surface outline, for the given three-dimensional viewport v
++ which is of domain \spadtype{ThreeDimensionalViewport}, if s is
++ "on", or does not display the diagonals if s is "off".

outlineRender : (%,S) -> Void
++ outlineRender(v,s) displays the polygon outline showing either
++ triangularized surface or a quadrilateral surface outline depending
++ on the whether the \spadfun{diagonals} function has been set, for
++ the given three-dimensional viewport v which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the polygon outline if s is "off".

drawStyle : (%,S) -> Void
++ drawStyle(v,s) displays the surface for the given three-dimensional
++ viewport v which is of domain \spadtype{ThreeDimensionalViewport}
++ in the style of drawing indicated by s. If s is not a valid
++ drawing style the style is wireframe by default. Possible
++ styles are \spad{"shade"}, \spad{"solid"} or \spad{"opaque"},
++ \spad{"smooth"}, and \spad{"wireMesh"}.

rotate : (%,F,F) -> Void
++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
++ \spad{th} radians and the latitudinal view angle \spad{phi} radians
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.

rotate : (%,I,I) -> Void

```

```

++ rotate(v,th,phi) rotates the graph to the longitudinal view angle
++ \spad{th} degrees and the latitudinal view angle \spad{phi} degrees
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}. The new rotation position
++ is not displayed until the function \spadfun{makeViewport3D} is
++ executed again for v.

zoom : (%,F) -> Void
++ zoom(v,s) sets the graph scaling factor to s, for the viewport v,
++ which is of the domain \spadtype{ThreeDimensionalViewport}.

zoom : (%,F,F,F) -> Void
++ zoom(v,sx,sy,sz) sets the graph scaling factors for the x-coordinate
++ axis to \spad{sx}, the y-coordinate axis to \spad{sy} and the
++ z-coordinate axis to \spad{sz} for the viewport v, which is of
++ the domain \spadtype{ThreeDimensionalViewport}.

translate : (%,F,F) -> Void
++ translate(v,dx,dy) sets the horizontal viewport offset to \spad{dx}
++ and the vertical viewport offset to \spad{dy}, for the viewport v,
++ which is of the domain \spadtype{ThreeDimensionalViewport}.

perspective : (%,S) -> Void
++ perspective(v,s) displays the graph in perspective if s is "on",
++ or does not display perspective if s is "off" for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.

eyeDistance : (%,F) -> Void
++ eyeDistance(v,d) sets the distance of the observer from the center
++ of the graph to d, for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.

hitherPlane : (%,F) -> Void
++ hitherPlane(v,h) sets the hither clipping plane of the graph to h,
++ for the viewport v, which is of the domain
++ \spadtype{ThreeDimensionalViewport}.

showRegion : (%,S) -> Void
++ showRegion(v,s) displays the bounding box of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the box if s is "off".

showClipRegion : (%,S) -> Void
++ showClipRegion(v,s) displays the clipping region of the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, if s is "on", or does not
++ display the region if s is "off".

```

```

clipSurface : (% , S) -> Void
++ clipSurface(v,s) displays the graph with the specified
++ clipping region removed if s is "on", or displays the graph
++ without clipping implemented if s is "off", for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.

lighting : (% , F, F, F) -> Void
++ lighting(v,x,y,z) sets the position of the light source to
++ the coordinates x, y, and z and displays the graph for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.

intensity : (% , F) -> Void
++ intensity(v,i) sets the intensity of the light source to i, for
++ the given three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.

reset : % -> Void
++ reset(v) sets the current state of the graph characteristics
++ of the given three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}, back to their initial settings.

colorDef : (% , C, C) -> Void
++ colorDef(v,c1,c2) sets the range of colors along the colormap so
++ that the lower end of the colormap is defined by \spad{c1} and the
++ top end of the colormap is defined by \spad{c2}, for the given
++ three-dimensional viewport, v, which is of domain
++ \spadtype{ThreeDimensionalViewport}.

write : (% , S) -> S
++ write(v,s) takes the given three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ file for v.

write : (% , S, S) -> S
++ write(v,s,f) takes the given three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ file for v and an optional file type f.

write : (% , S, L S) -> S
++ write(v,s,lf) takes the given three-dimensional viewport, v, which
++ is of domain \spadtype{ThreeDimensionalViewport}, and creates
++ a directory indicated by s, which contains the graph data
++ file for v and the optional file types indicated by the list lf.

close : % -> Void
++ close(v) closes the viewport window of the given

```

```

    ++ three-dimensional viewport, v, which is of domain
    ++ \spadtype{ThreeDimensionalViewport}, and terminates the
    ++ corresponding process ID.

key : % -> I
    ++ key(v) returns the process ID number of the given three-dimensional
    ++ viewport, v, which is of domain \spadtype{ThreeDimensionalViewport}.

— domain TUBE TubePlot —

```

)abbrev domain TUBE TubePlot
++ Author: Clifton J. Williamson
++ Date Created: Bastille Day 1989
++ Date Last Updated: 5 June 1990
++ Description:
++ Package for constructing tubes around 3-dimensional parametric curves.
++ Domain of tubes around 3-dimensional parametric curves.

TubePlot(Curve) : SIG == CODE where
  Curve : PlottableSpaceCurveCategory

  B   ==> Boolean
  L   ==> List
  Pt  ==> Point DoubleFloat

  SIG ==> with

    getCurve : % -> Curve
      ++ getCurve(t) returns the \spadtype{PlottableSpaceCurveCategory}
      ++ representing the parametric curve of the given tube plot t.

    listLoops : % -> L L Pt
      ++ listLoops(t) returns the list of lists of points, or the 'loops',
      ++ of the given tube plot t.

    closed? : % -> B
      ++ closed?(t) tests whether the given tube plot t is closed.

    open? : % -> B
      ++ open?(t) tests whether the given tube plot t is open.

    setClosed : (% , B) -> B
      ++ setClosed(t,b) declares the given tube plot t to be closed if
      ++ b is true, or if b is false, t is set to be open.

    tube : (Curve, L L Pt, B) -> %
      ++ tube(c,ll,b) creates a tube of the domain \spadtype{TubePlot} from a
      ++ space curve c of the category \spadtype{PlottableSpaceCurveCategory},
      ++ a list of lists of points (loops) ll and a boolean b which if
      ++ true indicates a closed tube, or if false an open tube.

=====

TwoDimensionalArray examples

=====

The TwoDimensionalArray domain is used for storing data in a two dimensional data structure indexed by row and by column. Such an array is a homogeneous data structure in that all the entries of the array must belong to the same Axiom domain.. Each array has a fixed

number of rows and columns specified by the user and arrays are not extensible. In Axiom, the indexing of two-dimensional arrays is one-based. This means that both the "first" row of an array and the "first" column of an array are given the index 1. Thus, the entry in the upper left corner of an array is in position (1,1).

The operation `new` creates an array with a specified number of rows and columns and fills the components of that array with a specified entry. The arguments of this operation specify the number of rows, the number of columns, and the entry.

This creates a five-by-four array of integers, all of whose entries are zero.

```
arr : ARRAY2 INT := new(5,4,0)
      +0  0  0  0+
      |      |
      |0  0  0  0|
      |      |
      |0  0  0  0|
      |      |
      |0  0  0  0|
      |      |
      +0  0  0  0+
                                     Type: TwoDimensionalArray Integer
```

The entries of this array can be set to other integers using `setelt`.

Issue this to set the element in the upper left corner of this array to 17.

```
setelt(arr,1,1,17)
17
                                     Type: PositiveInteger
```

Now the first element of the array is 17.

```
arr
      +17  0  0  0+
      |      |
      |0  0  0  0|
      |      |
      |0  0  0  0|
      |      |
      |0  0  0  0|
      |      |
      +0  0  0  0+
                                     Type: TwoDimensionalArray Integer
```

Likewise, elements of an array are extracted using the operation `elt`.

```
elt(arr,1,1)
17
```

Type: PositiveInteger

Another way to use these two operations is as follows. This sets the element in position (3,2) of the array to 15.

```
arr(3,2) := 15
15
```

Type: PositiveInteger

This extracts the element in position (3,2) of the array.

```
arr(3,2)
15
```

Type: PositiveInteger

The operations `elt` and `setelt` come equipped with an error check which verifies that the indices are in the proper ranges. For example, the above array has five rows and four columns, so if you ask for the entry in position (6,2) with `arr(6,2)` Axiom displays an error message. If there is no need for an error check, you can call the operations `qelt` and `qsetelt` which provide the same functionality but without the error check. Typically, these operations are called in well-tested programs.

The operations `row` and `column` extract rows and columns, respectively, and return objects of `OneDimensionalArray` with the same underlying element type.

```
row(arr,1)
[17,0,0,0]
```

Type: OneDimensionalArray Integer

```
column(arr,1)
[17,0,0,0,0]
```

Type: OneDimensionalArray Integer

You can determine the dimensions of an array by calling the operations `nrows` and `ncols`, which return the number of rows and columns, respectively.

```
nrows(arr)
5
```

Type: PositiveInteger

```
ncols(arr)
4
```

Type: PositiveInteger

To apply an operation to every element of an array, use `map`. This creates a new array. This expression negates every element.

```
map(-,arr)
+- 17  0  0 0+
|
| 0    0  0 0|
|
| 0    -15 0 0|
|
| 0    0  0 0|
|
+ 0    0  0 0+
Type: TwoDimensionalArray Integer
```

This creates an array where all the elements are doubled.

```
map((x +-> x + x),arr)
+34  0  0 0+
|
| 0    0  0 0|
|
| 0    30 0 0|
|
| 0    0  0 0|
|
+0    0  0 0+
Type: TwoDimensionalArray Integer
```

To change the array destructively, use `map` instead of `map`. If you need to make a copy of any array, use `copy`.

```
arrc := copy(arr)
+17  0  0 0+
|
| 0    0  0 0|
|
| 0    15 0 0|
|
| 0    0  0 0|
|
+0    0  0 0+
Type: TwoDimensionalArray Integer
```

```
map!(-,arrc)
+- 17  0  0 0+
|
| 0    0  0 0|
|
| 0    -15 0 0|
|
| 0    0  0 0|
```

```

      |      |
      + 0      0      0 0+
                                     Type: TwoDimensionalArray Integer

arrc
+- 17      0      0 0+
|
| 0      0      0 0|
|
| 0      - 15      0 0|
|
| 0      0      0 0|
|
+ 0      0      0 0+
                                     Type: TwoDimensionalArray Integer

arr
+17 0      0 0+
|
| 0      0      0 0|
|
| 0      15      0 0|
|
| 0      0      0 0|
|
+0 0      0 0+
                                     Type: TwoDimensionalArray Integer

```

Use `member?` to see if a given element is in an array.

```

member?(17,arr)
true
                                     Type: Boolean

```

```

member?(10317,arr)
false
                                     Type: Boolean

```

To see how many times an element appears in an array, use `count`.

```

count(17,arr)
1
                                     Type: PositiveInteger

```

```

count(0,arr)
18
                                     Type: PositiveInteger

```

getPickedPoints : $ -> L POINT

```

```

++ getPickedPoints(x)
++ returns a list of small floats for the points the
++ user interactively picked on the viewport
++ for full integration into the system, some design
++ issues need to be addressed: for example, how to go through
++ the GraphImage interface, how to default to graphs, etc.

viewport2D : () -> $
++ viewport2D() returns an undefined two-dimensional viewport
++ of the domain \spadtype{TwoDimensionalViewport} whose
++ contents are empty.

makeViewport2D : $ -> $
++ makeViewport2D(v) takes the given two-dimensional viewport,
++ v, of the domain \spadtype{TwoDimensionalViewport} and
++ displays a viewport window on the screen which contains
++ the contents of v.

options : $ -> L DROP
++ options(v) takes the given two-dimensional viewport, v, of the
++ domain \spadtype{TwoDimensionalViewport} and returns a list
++ containing the draw options from the domain \spadtype{DrawOption}
++ for v.

options : ($,L DROP) -> $
++ options(v,lopt) takes the given two-dimensional viewport, v,
++ of the domain \spadtype{TwoDimensionalViewport} and returns
++ v with it's draw options modified to be those which are indicated
++ in the given list, \spad{lopt} of domain \spadtype{DrawOption}.

makeViewport2D : (G,L DROP) -> $
++ makeViewport2D(gi,lopt) creates and displays a viewport window
++ of the domain \spadtype{TwoDimensionalViewport} whose graph
++ field is assigned to be the given graph, \spad{gi}, of domain
++ \spadtype{GraphImage}, and whose options field is set to be
++ the list of options, \spad{lopt} of domain \spadtype{DrawOption}.

graphState : ($,PI,SF,SF,SF,SF,I,I,I,I,PAL,I,PAL,I) -> Void
++ graphState(v,num,sX,sY,dX,dY,pts,lms,box,axes,axesC,un,unC,cP)
++ sets the state of the characteristics for the graph indicated
++ by \spad{num} in the given two-dimensional viewport v, of domain
++ \spadtype{TwoDimensionalViewport}, to the values given as
++ parameters. The scaling of the graph in the x and y component
++ directions is set to be \spad{sX} and \spad{sY}; the window
++ translation in the x and y component directions is set to be
++ \spad{dX} and \spad{dY}; The graph points, lines, bounding box,
++ axes, or units will be shown in the viewport if their given
++ parameters \spad{pts}, \spad{lms}, \spad{box}, \spad{axes} or
++ \spad{un} are set to be \spad{1}, but will not be shown if they
++ are set to \spad{0}. The color of the axes and the color of the

```

```

++ units are indicated by the palette colors \spad{axesC} and
++ \spad{unC} respectively. To display the control panel when
++ the viewport window is displayed, set \spad{cP} to \spad{1},
++ otherwise set it to \spad{0}.

graphStates : $ -> V GS
++ graphStates(v) returns and shows a listing of a record containing
++ the current state of the characteristics of each of the ten graph
++ records in the given two-dimensional viewport, v, which is of
++ domain \spadtype{TwoDimensionalViewport}.

graphs : $ -> V GU
++ graphs(v) returns a vector, or list, which is a union of all
++ the graphs, of the domain \spadtype{GraphImage}, which are
++ allocated for the two-dimensional viewport, v, of domain
++ \spadtype{TwoDimensionalViewport}. Those graphs which have
++ no data are labeled "undefined", otherwise their contents
++ are shown.

title : ($,STR) -> Void
++ title(v,s) changes the title which is shown in the two-dimensional
++ viewport window, v of domain \spadtype{TwoDimensionalViewport}.

putGraph : ($,G,PI) -> Void
++ putGraph(v,gi,n) sets the graph field indicated by n, of the
++ indicated two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, to be the graph, \spad{gi}
++ of domain \spadtype{GraphImage}. The contents of viewport, v,
++ will contain \spad{gi} when the function \spadfun{makeViewport2D}
++ is called to create the an updated viewport v.

getGraph : ($,PI) -> G
++ getGraph(v,n) returns the graph which is of the domain
++ \spadtype{GraphImage} which is located in graph field n
++ of the given two-dimensional viewport, v, which is of the
++ domain \spadtype{TwoDimensionalViewport}.

axes : ($,PI,STR) -> Void
++ axes(v,n,s) displays the axes of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the axes if s is "off".

axes : ($,PI,PAL) -> Void
++ axes(v,n,c) displays the axes of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, with the axes color set to
++ the given palette color c.

units : ($,PI,STR) -> Void

```

```

++ units(v,n,s) displays the units of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the units if s is "off".

units : ($,PI,PAL) -> Void
++ units(v,n,c) displays the units of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, with the units color set to
++ the given palette color c.

points : ($,PI,STR) -> Void
++ points(v,n,s) displays the points of the graph in field n of
++ the given two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or does
++ not display the points if s is "off".

region : ($,PI,STR) -> Void
++ region(v,n,s) displays the bounding box of the graph in
++ field n of the given two-dimensional viewport, v, which is
++ of domain \spadtype{TwoDimensionalViewport}, if s is "on",
++ or does not display the bounding box if s is "off".

connect : ($,PI,STR) -> Void
++ connect(v,n,s) displays the lines connecting the graph
++ points in field n of the given two-dimensional viewport, v,
++ which is of domain \spadtype{TwoDimensionalViewport}, if s
++ is "on", or does not display the lines if s is "off".

controlPanel : ($,STR) -> Void
++ controlPanel(v,s) displays the control panel of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, if s is "on", or hides
++ the control panel if s is "off".

close : $ -> Void
++ close(v) closes the viewport window of the given
++ two-dimensional viewport, v, which is of domain
++ \spadtype{TwoDimensionalViewport}, and terminates the
++ corresponding process ID.

dimensions : ($,NNI,NNI,PI,PI) -> Void
++ dimensions(v,x,y,width,height) sets the position of the
++ upper left-hand corner of the two-dimensional viewport, v,
++ which is of domain \spadtype{TwoDimensionalViewport}, to
++ the window coordinate x, y, and sets the dimensions of the
++ window to that of \spad{width}, \spad{height}. The new
++ dimensions are not displayed until the function
++ \spadfun{makeViewport2D} is executed again for v.

```

```

scale : ($,PI,F,F) -> Void
  ++ scale(v,n,sx,sy) displays the graph in field n of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, scaled by the factor \spad{sx}
  ++ in the x-coordinate direction and by the factor \spad{sy} in
  ++ the y-coordinate direction.

translate : ($,PI,F,F) -> Void
  ++ translate(v,n,dx,dy) displays the graph in field n of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, translated by \spad{dx} in
  ++ the x-coordinate direction from the center of the viewport, and
  ++ by \spad{dy} in the y-coordinate direction from the center.
  ++ Setting \spad{dx} and \spad{dy} to \spad{0} places the center
  ++ of the graph at the center of the viewport.

show : ($,PI,STR) -> Void
  ++ show(v,n,s) displays the graph in field n of the given
  ++ two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, if s is "on", or does not
  ++ display the graph if s is "off".

move : ($,NNI,NNI) -> Void
  ++ move(v,x,y) displays the two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport}, with the upper
  ++ left-hand corner of the viewport window at the screen
  ++ coordinate position x, y.

update : ($,G,PI) -> Void
  ++ update(v,gr,n) drops the graph \spad{gr} in slot \spad{n}
  ++ of viewport \spad{v}. The graph gr must have been
  ++ transmitted already and acquired an integer key.

resize : ($,PI,PI) -> Void
  ++ resize(v,w,h) displays the two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport}, with a width
  ++ of w and a height of h, keeping the upper left-hand corner
  ++ position unchanged.

write : ($,STR) -> STR
  ++ write(v,s) takes the given two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport}, and creates
  ++ a directory indicated by s, which contains the graph data
  ++ files for v.

write : ($,STR,STR) -> STR
  ++ write(v,s,f) takes the given two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport}, and creates
  ++ a directory indicated by s, which contains the graph data
  ++ files for v and an optional file type f.

```

```

write : ($,STR,L STR) -> STR
  ++ write(v,s,lf) takes the given two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport}, and creates
  ++ a directory indicated by s, which contains the graph data
  ++ files for v and the optional file types indicated by the list lf.

reset : $ -> Void
  ++ reset(v) sets the current state of the graph characteristics
  ++ of the given two-dimensional viewport, v, which is of domain
  ++ \spadtype{TwoDimensionalViewport}, back to their initial settings.

key : $ -> I
  ++ key(v) returns the process ID number of the given two-dimensional
  ++ viewport, v, which is of domain \spadtype{TwoDimensionalViewport}.

coerce : $ -> E
  ++ coerce(v) returns the given two-dimensional viewport, v, which
  ++ is of domain \spadtype{TwoDimensionalViewport} as output of
  ++ the domain \spadtype{OutputForm}.

=====

UnivariateLaurentSeries examples

=====

UnivariateLaurentSeries is a domain representing Laurent series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `UnivariateLaurentSeries(Integer,x,3)` represents Laurent series in $(x - 3)$ with integer coefficients.

— domain ULS UnivariateLaurentSeries —

```

)abbrev domain ULS UnivariateLaurentSeries
++ Author: Clifton J. Williamson
++ Date Created: 18 January 1990
++ Date Last Updated: 21 September 1993
++ Description:
++ Dense Laurent series in one variable
++ \spadtype{UnivariateLaurentSeries} is a domain representing Laurent
++ series in one variable with coefficients in an arbitrary ring. The
++ parameters of the type specify the coefficient ring, the power series
++ variable, and the center of the power series expansion. For example,
++ \spad{UnivariateLaurentSeries(Integer,x,3)} represents Laurent series in
++ \spad{(x - 3)} with integer coefficients.

UnivariateLaurentSeries(Coef,var,cen) : SIG == CODE where
  Coef : Ring
  var : Symbol
  cen : Coef

  I ==> Integer
  UTS ==> UnivariateTaylorSeries(Coef,var,cen)

  SIG ==> UnivariateLaurentSeriesConstructorCategory(Coef,UTS) with

    coerce : Variable(var) -> %
      ++ \spad{coerce(var)} converts the series variable \spad{var} into a
      ++ Laurent series.

    differentiate : (% ,Variable(var)) -> %
      ++ \spad{differentiate(f(x),x)} returns the derivative of
      ++ \spad{f(x)} with respect to \spad{x}.

    if Coef has Algebra Fraction Integer then

      integrate : (% ,Variable(var)) -> %
        ++ \spad{integrate(f(x))} returns an anti-derivative of the power
        ++ series \spad{f(x)} with constant coefficient 0.
        ++ We may integrate a series when we can divide coefficients
        ++ by integers.

  CODE ==> UnivariateLaurentSeriesConstructor(Coef,UTS) add

    variable x == var

    center x == cen

    coerce(v:Variable(var)) ==
      zero? cen => monomial(1,1)

```

```

monomial(1,1) + monomial(cen,0)

differentiate(x:%,v:Variable(var)) == differentiate x

if Coef has Algebra Fraction Integer then

  integrate(x:%,v:Variable(var)) == integrate x

```

=====

UnivariateLaurentSeriesConstructor examples

=====

This package enables one to construct a univariate Laurent series domain from a univariate Taylor series domain. Univariate Laurent series are represented by a pair $[n, f(x)]$, where n is an arbitrary integer and $f(x)$ is a Taylor series. This pair represents the Laurent series $x^n * f(x)$.

=====

UnivariatePolynomial examples

=====

The domain constructor `UnivariatePolynomial` (abbreviated `UP`) creates domains of univariate polynomials in a specified variable. For example, the domain `UP(a1,POLY FRAC INT)` provides polynomials in the single variable `a1` whose coefficients are general polynomials with rational number coefficients.

Restriction: Axiom does not allow you to create types where `UnivariatePolynomial` is contained in the coefficient type of `Polynomial`. Therefore, `UP(x,POLY INT)` is legal but `POLY UP(x,INT)`

is not.

$UP(x,INT)$ is the domain of polynomials in the single variable x with integer coefficients.

```
(p,q) : UP(x,INT)
```

Type: Void

```
p := (3*x-1)**2 * (2*x + 8)
```

$$18x^3 + 60x^2 - 46x + 8$$

Type: UnivariatePolynomial(x,Integer)

```
q := (1 - 6*x + 9*x**2)**2
```

$$81x^4 - 108x^3 + 54x^2 - 12x + 1$$

Type: UnivariatePolynomial(x,Integer)

The usual arithmetic operations are available for univariate polynomials.

```
p**2 + p*q
```

$$1458x^7 + 3240x^6 - 7074x^5 + 10584x^4 - 9282x^3 + 4120x^2 - 878x + 72$$

Type: UnivariatePolynomial(x,Integer)

The operation `leadingCoefficient` extracts the coefficient of the term of highest degree.

```
leadingCoefficient p
```

18

Type: PositiveInteger

The operation `degree` returns the degree of the polynomial. Since the polynomial has only one variable, the variable is not supplied to operations like `degree`.

```
degree p
```

3

Type: PositiveInteger

The `reductum` of the polynomial, the polynomial obtained by subtracting the term of highest order, is returned by `reductum`.

```
reductum p
```

$$60x^2 - 46x + 8$$

Type: UnivariatePolynomial(x,Integer)

The operation `gcd` computes the greatest common divisor of two polynomials.

The operation `lcm` computes the least common multiple.

[illegible]

This substitutes p for the variable in q .

```

q(p)
      12      11      10      9      8
      8503056x  + 113374080x  + 479950272x  + 404997408x  - 1369516896x
+
      7      6      5      4      3
      - 626146848x  + 2939858712x  - 2780728704x  + 1364312160x  - 396838872x
+
      2
      69205896x  - 6716184x + 279841
                                     Type: UnivariatePolynomial(x,Integer)

```

To obtain a list of coefficients of the polynomial, use `coefficients`.

```

l := coefficients p
    [18,60,- 46,8]
                                     Type: List Integer

```

From this you can use `gcd` and `reduce` to compute the content of the polynomial.

```

reduce(gcd,l)
      2
                                     Type: PositiveInteger

```

Alternatively (and more easily), you can just call `content`.

```

content p
      2
                                     Type: PositiveInteger

```

Note that the operation `coefficients` omits the zero coefficients from the list. Sometimes it is useful to convert a univariate polynomial to a vector whose i -th position contains the degree $i-1$ coefficient of the polynomial.

```

ux := (x**4+2*x+3)::UP(x,INT)
      4
      x  + 2x + 3
                                     Type: UnivariatePolynomial(x,Integer)

```

To get a complete vector of coefficients, use the operation `vectorise`, which takes a univariate polynomial and an integer denoting the length of the desired vector.

```

vectorise(ux,5)
    [3,2,0,0,1]
                                     Type: Vector Integer

```

It is common to want to do something to every term of a polynomial,

creating a new polynomial in the process.

This is a function for iterating across the terms of a polynomial, squaring each term.

```
squareTerms(p) == reduce(+,[t**2 for t in monomials p])
Type: Void
```

Recall what p looked like.

```
p
      3      2
    18x  + 60x  - 46x + 8
Type: UnivariatePolynomial(x,Integer)
```

We can demonstrate squareTerms on p.

```
squareTerms p
      6      4      2
    324x  + 3600x  + 2116x  + 64
Type: UnivariatePolynomial(x,Integer)
```

When the coefficients of the univariate polynomial belong to a field, it is possible to compute quotients and remainders. For example, when the coefficients are rational numbers, as opposed to integers. The important property of a field is that non-zero elements can be divided and produce another element. The quotient of the integers 2 and 3 is not another integer.

```
(r,s) : UP(a1,FRAC INT)
Type: Void

r := a1**2 - 2/3
      2      2
    a1  - -
      3
Type: UnivariatePolynomial(a1,Fraction Integer)

s := a1 + 4
    a1 + 4
Type: UnivariatePolynomial(a1,Fraction Integer)
```

When the coefficients are rational numbers or rational expressions, the operation quo computes the quotient of two polynomials.

```
r quo s
    a1 - 4
Type: UnivariatePolynomial(a1,Fraction Integer)
```

The operation rem computes the remainder.

```

r rem s
  46
  --
  3
                                     Type: UnivariatePolynomial(a1,Fraction Integer)

```

The operation divide can be used to return a record of both components.

```

d := divide(r, s)
                                     46
[quotient= a1 - 4,remainder= --]
                                     3
                                     Type: Record(quotient: UnivariatePolynomial(a1,Fraction Integer),
                                     remainder: UnivariatePolynomial(a1,Fraction Integer))

```

Now we check the arithmetic!

```

r - (d.quotient * s + d.remainder)
  0
                                     Type: UnivariatePolynomial(a1,Fraction Integer)

```

It is also possible to integrate univariate polynomials when the coefficients belong to a field.

```

integrate r
  1  3  2
- a1 - - a1
  3    3
                                     Type: UnivariatePolynomial(a1,Fraction Integer)

```

```

integrate s
  1  2
- a1 + 4a1
  2
                                     Type: UnivariatePolynomial(a1,Fraction Integer)

```

One application of univariate polynomials is to see expressions in terms of a specific variable.

We start with a polynomial in a1 whose coefficients are quotients of polynomials in b1 and b2.

```

t : UP(a1,FRAC POLY INT)
                                     Type: Void

```

Since in this case we are not talking about using multivariate polynomials in only two variables, we use Polynomial. We also use Fraction because we want fractions.

```

t := a1**2 - a1/b2 + (b1**2-b1)/(b2+3)
      2
      2    1    b1  - b1
a1  - -- a1 + -----
      b2      b2 + 3
Type: UnivariatePolynomial(a1,Fraction Polynomial Integer)

```

We push all the variables into a single quotient of polynomials.

```

u : FRAC POLY INT := t
      2 2    2    2
a1 b2  + (b1  - b1 + 3a1  - a1)b2 - 3a1
-----
      2
      b2  + 3b2
Type: Fraction Polynomial Integer

```

Alternatively, we can view this as a polynomial in the variable This is a mode-directed conversion: you indicate as much of the structure as you care about and let Axiom decide on the full type and how to do the transformation.

```

u :: UP(b1,?)
      1    2    1    2
----- b1  - ----- b1 + -----
b2 + 3    b2 + 3    b2
Type: UnivariatePolynomial(b1,Fraction Polynomial Integer)

```

=====
UnivariatePuisseuxSeries examples
=====

```

UnivariatePuisseuxSeries is a domain representing Puiseux series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `UnivariatePuisseuxSeries(Integer,x,3)` represents Puiseux series in $(x - 3)$ with Integer coefficients.

UnivariatePuisseuxSeriesConstructor examples

=====

This package enables one to construct a univariate Puiseux series domain from a univariate Laurent series domain. Univariate Puiseux series are represented by a pair $[r, f(x)]$, where r is a positive rational number and $f(x)$ is a Laurent series. This pair represents the Puiseux series $f(x^r)$.

UnivariatePuisseuxSeriesWithExponentialSingularity examples

=====

UnivariatePuisseuxSeriesWithExponentialSingularity is a domain used to represent functions with essential singularities. Objects in this domain are sums, where each term in the sum is a univariate Puiseux series times the exponential of a univariate Puiseux series. Thus, the elements of this domain are sums of expressions of the form $g(x) * \exp(f(x))$, where $g(x)$ is a univariate Puiseux series and $f(x)$ is a univariate Puiseux series with no terms of non-negative degree.
