SYNOPSIS
   Functions/Subroutines
       subroutine cgesvx (FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED,
           R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
            CGESVX computes the solution to system of linear equations A * X =
           B for GE matrices

Function/Subroutine Documentation
   subroutine cgesvx (character FACT, character TRANS, integer N, integer
       NRHS, complex, dimension( lda, * ) A, integer LDA, complex, dimension(
       ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, character
       EQUED, real, dimension( * ) R, real, dimension( * ) C, complex,
       dimension( ldb, * ) B, integer LDB, complex, dimension( ldx, * ) X,
       integer LDX, real RCOND, real, dimension( * ) FERR, real, dimension( *
       ) BERR, complex, dimension( * ) WORK, real, dimension( * ) RWORK,
       integer INFO)
        CGESVX computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:

   CGESVX uses the LU factorization to compute the solution to a complex
   system of linear equations
       A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
       TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
       TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
       TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
     Whether or not the system will be equilibrated depends on the
     scaling of the matrix A, but if equilibration is used, A is
     overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
     or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
        A = P * L * U,
```

```
      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates
      for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
```

```
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by CGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by CGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
```

```
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
          EQUED is an input argument if FACT = 'F'; otherwise, it is an
          output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by
  diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
  overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
```

```
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)
  On exit, RWORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If RWORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  RWORK(1) contains the reciprocal pivot growth factor for the
  leading INFO columns of A.

INFO
  INFO is INTEGER
  = 0:  successful exit
```

```
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, and i is
      <= N:  U(i,i) is exactly zero.  The factorization has
             been completed, but the factor U is exactly
             singular, so the solution and error bounds
             could not be computed. RCOND = 0 is returned.
      = N+1: U is nonsingular, but RCOND is less than machine
             precision, meaning that the matrix is singular
             to working precision.  Nevertheless, the
             solution and error bounds are computed because
             there are a number of situations where the
             computed solution can be more accurate than the
             value of RCOND would suggest.

        CGESVXX computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:
   CGESVXX uses the LU factorization to compute the solution to a
   complex system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CGESVXX would itself produce.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
```

```
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as
         A = P * L * U,
      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND). If the reciprocal of the condition number is less
      than machine precision, the routine still goes on to solve for X
      and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
```

```
          A, AF, and IPIV are not modified.
  = 'N':  The matrix A will be copied to AF and factored.
  = 'E':  The matrix A will be equilibrated if necessary, then
          copied to AF and factored.

TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate Transpose)

 N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

 A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

 LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

 AF
  AF is COMPLEX array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by CGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
```

```
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by CGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
```

```
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
```

```
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In CGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
    max_j (abs(XTRUE(j,i) - X(j,i)))
    ------------------------------
         max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
```

```
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
           abs(XTRUE(j,i) - X(j,i))
     max_j ----------------------
                 abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then

  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
```

```
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.

  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.

  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
  factorizations or factorizations other than LU. If
  the factorization uses a technique other than
  Gaussian elimination, the guarantees in
  err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.

  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
```

```
  RWORK is REAL array, dimension (2*N)

 INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
    has been completed, but the factor U is exactly singular, so
    the solution and error bounds could not be computed. RCOND = 0
    is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
    not guaranteed. The solutions corresponding to other right-
    hand sides K with K > J may not be guaranteed as well, but
    only the first such right-hand side is reported. If a small
    componentwise error is not requested (PARAMS(3) = 0.0) then
    the Jth right-hand side is the first with a normwise error
    bound that is not guaranteed (the smallest J such
    that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
    the Jth right-hand side is the first with either a normwise or
    componentwise error bound that is not guaranteed (the smallest
    J such that either ERR_BNDS_NORM(J,1) = 0.0 or
    ERR_BNDS_COMP(J,1) = 0.0). See the definition of
    ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
    about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine zcgesv (N, NRHS, A, LDA, IPIV, B, LDB, X, LDX, WORK, SWORK,
           RWORK, ITER, INFO)
            ZCGESV computes the solution to system of linear equations A * X =
           B for GE matrices (mixed precision with iterative refinement)

Function/Subroutine Documentation
   subroutine zcgesv (integer N, integer NRHS, complex*16, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, complex*16, dimension(
       ldb, * ) B, integer LDB, complex*16, dimension( ldx, * ) X, integer
       LDX, complex*16, dimension( n, * ) WORK, complex, dimension( * ) SWORK,
       double precision, dimension( * ) RWORK, integer ITER, integer INFO)
        ZCGESV computes the solution to system of linear equations A * X = B
       for GE matrices (mixed precision with iterative refinement)

Purpose:
   ZCGESV computes the solution to a complex system of linear equations
              A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   ZCGESV first attempts to factorize the matrix in COMPLEX and use this
   factorization within an iterative refinement procedure to produce a
   solution with COMPLEX*16 normwise backward error quality (see below).
   If the approach fails the method switches to a COMPLEX*16
   factorization and solve.

   The iterative refinement is not going to be a winning strategy if
   the ratio COMPLEX performance over COMPLEX*16 performance is too
   small. A reasonable strategy should take the number of right-hand
   sides and the size of the matrix into account. This might be done
   with a call to ILAENV in the future. Up to now, we always try
   iterative refinement.

   The iterative refinement process is stopped if
         ITER > ITERMAX
   or for all the RHS we have:
         RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
   where
   o ITER is the number of the current iteration in the iterative
   refinement process
   o RNRM is the infinity-norm of the residual
   o XNRM is the infinity-norm of the solution
   o ANRM is the infinity-operator-norm of the matrix A
   o EPS is the machine epsilon returned by DLAMCH('Epsilon')
```

```
   The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array,
   dimension (LDA,N)
   On entry, the N-by-N coefficient matrix A.
   On exit, if iterative refinement has been successfully used
   (INFO.EQ.0 and ITER.GE.0, see description below), then A is
   unchanged, if double precision factorization has been used
   (INFO.EQ.0 and ITER.LT.0, see description below), then the
   array A contains the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices that define the permutation matrix P;
   row i of the matrix was interchanged with row IPIV(i).
   Corresponds either to the single precision factorization
   (if INFO.EQ.0 and ITER.GE.0) or the double precision
   factorization (if INFO.EQ.0 and ITER.LT.0).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   The N-by-NRHS right hand side matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 X
   X is COMPLEX*16 array, dimension (LDX,NRHS)
   If INFO = 0, the N-by-NRHS solution matrix X.

 LDX
   LDX is INTEGER
```

```
  The leading dimension of the array X.  LDX >= max(1,N).

WORK
  WORK is COMPLEX*16 array, dimension (N*NRHS)
  This array is used to hold the residual vectors.

SWORK
  SWORK is COMPLEX array, dimension (N*(N+NRHS))
  This array is used to use the single precision matrix and the
  right-hand sides or solutions in single precision.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

ITER
  ITER is INTEGER
  < 0: iterative refinement has failed, COMPLEX*16
       factorization has been performed
  -1 : the routine fell back to full precision for
       implementation- or machine-specific reasons
  -2 : narrowing the precision induced an overflow,
       the routine fell back to full precision
  -3 : failure of CGETRF
  -31: stop the iterative refinement after the 30th
       iterations
  > 0: iterative refinement has been sucessfully used.
       Returns the number of iterations

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) computed in COMPLEX*16 is exactly
        zero.  The factorization has been completed, but the
        factor U is exactly singular, so the solution
        could not be computed.

SYNOPSIS
   Functions/Subroutines
       subroutine zgels (TRANS, M, N, NRHS, A, LDA, B, LDB, WORK, LWORK, INFO)
            ZGELS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine zgels (character TRANS, integer M, integer N, integer NRHS,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldb, * ) B, integer LDB, complex*16, dimension( * ) WORK, integer
       LWORK, integer INFO)
        ZGELS solves overdetermined or underdetermined systems for GE matrices

Purpose:
   1. If TRANS = 'N' and m >= n:  find the least squares solution of
      an overdetermined system, i.e., solve the least squares problem
          minimize || B - A*X ||.

   2. If TRANS = 'N' and m < n:  find the minimum norm solution of
      an underdetermined system A * X = B.

   3. If TRANS = 'C' and m >= n:  find the minimum norm solution of
      an undetermined system A**H * X = B.

   4. If TRANS = 'C' and m < n:  find the least squares solution of
```

```
      an overdetermined system, i.e., solve the least squares problem
           minimize || B - A**H * X ||.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N': the linear system involves A;
   = 'C': the linear system involves A**H.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of
   columns of the matrices B and X. NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   if M >= N, A is overwritten by details of its QR
              factorization as returned by ZGEQRF;
   if M <  N, A is overwritten by details of its LQ
              factorization as returned by ZGELQF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the matrix B of right hand side vectors, stored
   columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS
   if TRANS = 'C'.
   On exit, if INFO = 0, B is overwritten by the solution
   vectors, stored columnwise:
   if TRANS = 'N' and m >= n, rows 1 to n of B contain the least
   squares solution vectors; the residual sum of squares for the
   solution in each column is given by the sum of squares of the
   modulus of elements N+1 to M in that column;
```

```
  if TRANS = 'N' and m < n, rows 1 to N of B contain the
  minimum norm solution vectors;
  if TRANS = 'C' and m >= n, rows 1 to M of B contain the
  minimum norm solution vectors;
  if TRANS = 'C' and m < n, rows 1 to M of B contain the
  least squares solution vectors; the residual sum of squares
  for the solution in each column is given by the sum of
  squares of the modulus of elements M+1 to N in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= MAX(1,M,N).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= max( 1, MN + max( MN, NRHS ) ).
  For optimal performance,
  LWORK >= max( 1, MN + max( MN, NRHS )*NB ).
  where MN = min(M,N) and NB is the optimum block size.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO =  i, the i-th diagonal element of the
        triangular factor of A is zero, so that A does not have
        full rank; the least squares solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgelsd (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, RWORK, IWORK, INFO)
            ZGELSD computes the minimum-norm solution to a linear least
           squares problem for GE matrices

Function/Subroutine Documentation
   subroutine zgelsd (integer M, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, double precision, dimension( * ) S, double precision
       RCOND, integer RANK, complex*16, dimension( * ) WORK, integer LWORK,
       double precision, dimension( * ) RWORK, integer, dimension( * ) IWORK,
       integer INFO)
        ZGELSD computes the minimum-norm solution to a linear least squares
       problem for GE matrices
```

```
Purpose:
   ZGELSD computes the minimum-norm solution to a real linear least
   squares problem:
          minimize 2-norm(| b - A*x |)
   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The problem is solved in three steps:
   (1) Reduce the coefficient matrix A to bidiagonal form with
       Householder tranformations, reducing the original problem
       into a "bidiagonal least squares problem" (BLS)
   (2) Solve the BLS using a divide and conquer approach.
   (3) Apply back all the Householder tranformations to solve
       the original least squares problem.

   The effective rank of A is determined by treating as zero those
   singular values which are less than RCOND times the largest singular
   value.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, A has been destroyed.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the M-by-NRHS right hand side matrix B.
  On exit, B is overwritten by the N-by-NRHS solution matrix X.
  If m >= n and RANK = n, the residual sum-of-squares for
  the solution in the i-th column is given by the sum of
  squares of the modulus of elements n+1:m in that column.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,M,N).

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is DOUBLE PRECISION
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK must be at least 1.
  The exact minimum amount of workspace needed depends on M,
  N and NRHS. As long as LWORK is at least
        2*N + N*NRHS
  if M is greater than or equal to N or
        2*M + M*NRHS
  if M is less than N, the code will execute correctly.
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the array WORK and the
```

```
  minimum sizes of the arrays RWORK and IWORK, and returns
  these values as the first entries of the WORK, RWORK and
  IWORK arrays, and no error message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (MAX(1,LRWORK))
  LRWORK >=
    10*N + 2*N*SMLSIZ + 8*N*NLVL + 3*SMLSIZ*NRHS +
    MAX( (SMLSIZ+1)**2, N*(1+NRHS) + 2*NRHS )
  if M is greater than or equal to N or
    10*M + 2*M*SMLSIZ + 8*M*NLVL + 3*SMLSIZ*NRHS +
    MAX( (SMLSIZ+1)**2, N*(1+NRHS) + 2*NRHS )
  if M is less than N, the code will execute correctly.
  SMLSIZ is returned by ILAENV and is equal to the maximum
  size of the subproblems at the bottom of the computation
  tree (usually about 25), and
    NLVL = MAX( 0, INT( LOG_2( MIN( M,N )/(SMLSIZ+1) ) ) + 1 )
  On exit, if INFO = 0, RWORK(1) returns the minimum LRWORK.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  LIWORK >= max(1, 3*MINMN*NLVL + 11*MINMN),
  where MINMN = MIN( M,N ).
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
        bidiagonal form did not converge to zero.

SYNOPSIS
   Functions/Subroutines
       subroutine zgelss (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
           LWORK, RWORK, INFO)
            ZGELSS solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine zgelss (integer M, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, double precision, dimension( * ) S, double precision
       RCOND, integer RANK, complex*16, dimension( * ) WORK, integer LWORK,
       double precision, dimension( * ) RWORK, integer INFO)
        ZGELSS solves overdetermined or underdetermined systems for GE
       matrices
```

```
Purpose:
   ZGELSS computes the minimum norm solution to a complex linear
   least squares problem:

   Minimize 2-norm(| b - A*x |).

   using the singular value decomposition (SVD) of A. A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The effective rank of A is determined by treating as zero those
   singular values which are less than RCOND times the largest singular value.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A. N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X. NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the first min(m,n) rows of A are overwritten with
   its right singular vectors, stored rowwise.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,M).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the M-by-NRHS right hand side matrix B.
   On exit, B is overwritten by the N-by-NRHS solution matrix X.
   If m >= n and RANK = n, the residual sum-of-squares for
   the solution in the i-th column is given by the sum of
   squares of the modulus of elements n+1:m in that column.

 LDB
```

```
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,M,N).

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A in decreasing order.
  The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND
  RCOND is DOUBLE PRECISION
  RCOND is used to determine the effective rank of A.
  Singular values S(i) <= RCOND*S(1) are treated as zero.
  If RCOND < 0, machine precision is used instead.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the number of singular values
  which are greater than RCOND*S(1).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 1, and also:
  LWORK >=  2*min(M,N) + max(M,N,NRHS)
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (5*min(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  the algorithm for computing the SVD failed to converge;
        if INFO = i, i off-diagonal elements of an intermediate
        bidiagonal form did not converge to zero.

SYNOPSIS
   Functions/Subroutines
       subroutine zgelsy (M, N, NRHS, A, LDA, B, LDB, JPVT, RCOND, RANK, WORK,
           LWORK, RWORK, INFO)
            ZGELSY solves overdetermined or underdetermined systems for GE
           matrices

Function/Subroutine Documentation
   subroutine zgelsy (integer M, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, integer, dimension( * ) JPVT, double precision RCOND,
       integer RANK, complex*16, dimension( * ) WORK, integer LWORK, double
       precision, dimension( * ) RWORK, integer INFO)
```

```
       ZGELSY solves overdetermined or underdetermined systems for GE
      matrices

Purpose:
   ZGELSY computes the minimum-norm solution to a complex linear least
   squares problem:
       minimize || A * X - B ||
   using a complete orthogonal factorization of A.  A is an M-by-N
   matrix which may be rank-deficient.

   Several right hand side vectors b and solution vectors x can be
   handled in a single call; they are stored as the columns of the
   M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

   The routine first computes a QR factorization with column pivoting:
          A * P = Q * [ R11 R12 ]
                      [  0  R22 ]
   with R11 defined as the largest leading submatrix whose estimated
   condition number is less than 1/RCOND.  The order of R11, RANK,
   is the effective rank of A.

   Then, R22 is considered to be negligible, and R12 is annihilated
   by unitary transformations from the right, arriving at the
   complete orthogonal factorization:
         A * P = Q * [ T11 0 ] * Z
                     [  0  0 ]
   The minimum-norm solution is then
         X = P * Z**H [ inv(T11)*Q1**H*B ]
                      [        0         ]
   where Q1 consists of the first RANK columns of Q.

   This routine is basically identical to the original xGELSX except
   three differences:
   o The permutation of matrix B (the right hand side) is faster and
     more simple.
   o The call to the subroutine xGEQPF has been substituted by the
     the call to the subroutine xGEQP3. This subroutine is a Blas-3
     version of the QR factorization with column pivoting.
   o Matrix B (the right hand side) is updated with Blas-3.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of
  columns of matrices B and X. NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, A has been overwritten by details of its
  complete orthogonal factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the M-by-NRHS right hand side matrix B.
  On exit, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,M,N).

JPVT
  JPVT is INTEGER array, dimension (N)
  On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted
  to the front of AP, otherwise column i is a free column.
  On exit, if JPVT(i) = k, then the i-th column of A*P
  was the k-th column of A.

RCOND
  RCOND is DOUBLE PRECISION
  RCOND is used to determine the effective rank of A, which
  is defined as the order of the largest leading triangular
  submatrix R11 in the QR factorization with pivoting of A,
  whose estimated condition number < 1/RCOND.

RANK
  RANK is INTEGER
  The effective rank of A, i.e., the order of the submatrix
  R11.  This is the same as the order of the submatrix T11
  in the complete orthogonal factorization of A.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
```

```
  The dimension of the array WORK.
  The unblocked strategy requires that:
  LWORK >= MN + MAX( 2*MN, N+1, MN+NRHS )
  where MN = min(M,N).
  The block algorithm requires that:
  LWORK >= MN + MAX( 2*MN, NB*(N+1), MN+MN*NB, MN+NB*NRHS )
  where NB is an upper bound on the blocksize returned
  by ILAENV for the routines ZGEQP3, ZTZRZF, CTZRQF, ZUNMQR,
  and ZUNMRZ.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

 RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgesv (N, NRHS, A, LDA, IPIV, B, LDB, INFO)
            ZGESV computes the solution to system of linear equations A * X =
           B for GE matrices (simple driver)

Function/Subroutine Documentation
   subroutine zgesv (integer N, integer NRHS, complex*16, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, complex*16, dimension(
       ldb, * ) B, integer LDB, integer INFO)
        ZGESV computes the solution to system of linear equations A * X = B
       for GE matrices (simple driver)

Purpose:
   ZGESV computes the solution to a complex system of linear equations
               A * X = B,
```

```
  where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

  The LU decomposition with partial pivoting and row interchanges is
  used to factor A as
              A = P * L * U,
  where P is a permutation matrix, L is unit lower triangular, and U is
  upper triangular.  The factored form of A is then used to solve the
  system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N coefficient matrix A.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices that define the permutation matrix P;
   row i of the matrix was interchanged with row IPIV(i).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the N-by-NRHS matrix of right hand side matrix B.
   On exit, if INFO = 0, the N-by-NRHS solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
         has been completed, but the factor U is exactly
```

```
singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgesvx (FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED,
           R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
            ZGESVX computes the solution to system of linear equations A * X =
           B for GE matrices

Function/Subroutine Documentation
   subroutine zgesvx (character FACT, character TRANS, integer N, integer
       NRHS, complex*16, dimension( lda, * ) A, integer LDA, complex*16,
       dimension( ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV,
       character EQUED, double precision, dimension( * ) R, double precision,
       dimension( * ) C, complex*16, dimension( ldb, * ) B, integer LDB,
       complex*16, dimension( ldx, * ) X, integer LDX, double precision RCOND,
       double precision, dimension( * ) FERR, double precision, dimension( * )
       BERR, complex*16, dimension( * ) WORK, double precision, dimension( * )
```

```
       RWORK, integer INFO)
        ZGESVX computes the solution to system of linear equations A * X = B
       for GE matrices

Purpose:
   ZGESVX uses the LU factorization to compute the solution to a complex
   system of linear equations
               A * X = B,
   where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
         A = P * L * U,
      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
```

```
  FACT is CHARACTER*1
  Specifies whether or not the factored form of the matrix A is
  supplied on entry, and if not, whether the matrix A should be
  equilibrated before it is factored.
  = 'F':  On entry, AF and IPIV contain the factored form of A.
          If EQUED is not 'N', the matrix A has been
          equilibrated with scaling factors given by R and C.
          A, AF, and IPIV are not modified.
  = 'N':  The matrix A will be copied to AF and factored.
  = 'E':  The matrix A will be equilibrated if necessary, then
          copied to AF and factored.

TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate transpose)

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by ZGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.
```

```
  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by ZGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is DOUBLE PRECISION array, dimension (N)
```

```
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by
  diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
  overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
```

```
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)
  On exit, RWORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If RWORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  RWORK(1) contains the reciprocal pivot growth factor for the
  leading INFO columns of A.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
    <= N:  U(i,i) is exactly zero.  The factorization has
      been completed, but the factor U is exactly
      singular, so the solution and error bounds
      could not be computed. RCOND = 0 is returned.
    = N+1: U is nonsingular, but RCOND is less than machine
      precision, meaning that the matrix is singular
      to working precision.  Nevertheless, the
      solution and error bounds are computed because
      there are a number of situations where the
      computed solution can be more accurate than the
      value of RCOND would suggest.

      INFO)
       ZGESVXX computes the solution to system of linear equations A * X = B
      for GE matrices

Purpose:
   ZGESVXX uses the LU factorization to compute the solution to a
   complex*16 system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZGESVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZGESVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZGESVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZGESVXX would itself produce.

Description:
   The following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:
   TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
   the matrix A (after equilibration if FACT = 'E') as
           A = P * L * U,
   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
```

```
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
```

```
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.  If FACT = 'F' and EQUED is
  not 'N', then A must have been equilibrated by the scaling
  factors in R and/or C.  A is not modified if FACT = 'F' or
  'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the factors L and U from the factorization
  A = P*L*U as computed by ZGETRF.  If EQUED .ne. 'N', then
  AF is the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by ZGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.
```

```
  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
```

```
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In ZGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
```

```
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * dlamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * dlamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*A, where S scales each row by a power of the
           radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
```

```
                    abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                          abs(X(j,i))
```

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields:

```
err = 1 "Trust/don't trust" boolean. Trust the answer if the
         reciprocal condition number is less than the threshold
         sqrt(n) * dlamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error,
         almost certainly within a factor of 10 of the true error
         so long as the next entry is greater than the threshold
         sqrt(n) * dlamch('Epsilon'). This error bound should only
         be trusted if the previous boolean is true.

err = 3  Reciprocal condition number: Estimated componentwise
         reciprocal condition number.  Compared with the threshold
         sqrt(n) * dlamch('Epsilon') to determine if the error
         estimate is "guaranteed". These reciprocal condition
         numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
         appropriately scaled matrix Z.
         Let Z = S*(A*diag(x)), where x is the solution for the
         current right-hand side and S scales each row of
         A*diag(x) by a power of the radix so all absolute row
         sums of Z are approximately 1.
```

NPARAMS

NPARAMS is INTEGER

Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS

PARAMS is DOUBLE PRECISION array, dimension NPARAMS

Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

```
  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be
              trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
         not guaranteed. The solutions corresponding to other right-
         hand sides K with K > J may not be guaranteed as well, but
         only the first such right-hand side is reported. If a small
         componentwise error is not requested (PARAMS(3) = 0.0) then
         the Jth right-hand side is the first with a normwise error
         bound that is not guaranteed (the smallest J such
         that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
         the Jth right-hand side is the first with either a normwise or
         componentwise error bound that is not guaranteed (the smallest
         J such that either ERR_BNDS_NORM(J,1) = 0.0 or
         ERR_BNDS_COMP(J,1) = 0.0). See the definition of
         ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
```

```
about all of the right-hand sides check ERR_BNDS_NORM or
ERR_BNDS_COMP.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgees (JOBVS, SORT, SELECT, N, A, LDA, SDIM, WR, WI, VS,
           LDVS, WORK, LWORK, BWORK, INFO)
            DGEES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine dgees (character JOBVS, character SORT, external SELECT, integer
       N, double precision, dimension( lda, * ) A, integer LDA, integer SDIM,
       double precision, dimension( * ) WR, double precision, dimension( * )
       WI, double precision, dimension( ldvs, * ) VS, integer LDVS, double
       precision, dimension( * ) WORK, integer LWORK, logical, dimension( * )
       BWORK, integer INFO)
        DGEES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   DGEES computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues, the real Schur form T, and, optionally, the matrix of
   Schur vectors Z.  This gives the Schur factorization A = Z*T*(Z**T).

   Optionally, it also orders the eigenvalues on the diagonal of the
   real Schur form so that selected eigenvalues are at the top left.
   The leading columns of Z then form an orthonormal basis for the
   invariant subspace corresponding to the selected eigenvalues.

   A matrix is in real Schur form if it is upper quasi-triangular with
   1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form
          [  a  b  ]
          [  c  a  ]

   where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Parameters:

 JOBVS
   JOBVS is CHARACTER*1
   = 'N': Schur vectors are not computed;
   = 'V': Schur vectors are computed.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the Schur form.
```

```
  = 'N': Eigenvalues are not ordered;
  = 'S': Eigenvalues are ordered (see SELECT).

SELECT
  SELECT is a LOGICAL FUNCTION of two DOUBLE PRECISION arguments
  SELECT must be declared EXTERNAL in the calling subroutine.
  If SORT = 'S', SELECT is used to select eigenvalues to sort
  to the top left of the Schur form.
  If SORT = 'N', SELECT is not referenced.
  An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if
  SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex
  conjugate pair of eigenvalues is selected, then both complex
  eigenvalues are selected.
  Note that a selected complex eigenvalue may no longer
  satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned); in this
  case INFO is set to N+2 (see INFO below).

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten by its real Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
        for which SELECT is true. (Complex conjugate
        pairs for which SELECT is true for either
        eigenvalue count as 2.)

WR
  WR is DOUBLE PRECISION array, dimension (N)

WI
  WI is DOUBLE PRECISION array, dimension (N)
  WR and WI contain the real and imaginary parts,
  respectively, of the computed eigenvalues in the same order
  that they appear on the diagonal of the output Schur form T.
  Complex conjugate pairs of eigenvalues will appear
  consecutively with the eigenvalue having the positive
```

```
  imaginary part first.

VS
  VS is DOUBLE PRECISION array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1; if
  JOBVS = 'V', LDVS >= N.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) contains the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,3*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0: if INFO = i, and i is
    <= N: the QR algorithm failed to compute all the
          eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI
          contain those eigenvalues which have converged; if
          JOBVS = 'V', VS contains the matrix which reduces A
          to its partially converged Schur form.
    = N+1: the eigenvalues could not be reordered because some
           eigenvalues were too close to separate (the problem
           is very ill-conditioned);
    = N+2: after reordering, roundoff changed values of some
           complex eigenvalues so that leading eigenvalues in
           the Schur form no longer satisfy SELECT=.TRUE.  This
           could also be caused by underflow due to scaling.

          ======

SYNOPSIS
   Functions/Subroutines
       subroutine dgeesx (JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, WR, WI,
           VS, LDVS, RCONDE, RCONDV, WORK, LWORK, IWORK, LIWORK, BWORK, INFO)
            DGEESX computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine dgeesx (character JOBVS, character SORT, external SELECT,
       character SENSE, integer N, double precision, dimension( lda, * ) A,
       integer LDA, integer SDIM, double precision, dimension( * ) WR, double
       precision, dimension( * ) WI, double precision, dimension( ldvs, * )
       VS, integer LDVS, double precision RCONDE, double precision RCONDV,
       double precision, dimension( * ) WORK, integer LWORK, integer,
       dimension( * ) IWORK, integer LIWORK, logical, dimension( * ) BWORK,
       integer INFO)
        DGEESX computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   DGEESX computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues, the real Schur form T, and, optionally, the matrix of
   Schur vectors Z.  This gives the Schur factorization A = Z*T*(Z**T).

   Optionally, it also orders the eigenvalues on the diagonal of the
```

```
  real Schur form so that selected eigenvalues are at the top left;
  computes a reciprocal condition number for the average of the
  selected eigenvalues (RCONDE); and computes a reciprocal condition
  number for the right invariant subspace corresponding to the
  selected eigenvalues (RCONDV).  The leading columns of Z form an
  orthonormal basis for this invariant subspace.

  For further explanation of the reciprocal condition numbers RCONDE
  and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where
  these quantities are called s and sep respectively).

  A real matrix is in real Schur form if it is upper quasi-triangular
  with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in
  the form
           [  a  b  ]
           [  c  a  ]

  where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Parameters:

 JOBVS
  JOBVS is CHARACTER*1
  = 'N': Schur vectors are not computed;
  = 'V': Schur vectors are computed.

 SORT
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the Schur form.
  = 'N': Eigenvalues are not ordered;
  = 'S': Eigenvalues are ordered (see SELECT).

 SELECT
  SELECT is procedure) LOGICAL FUNCTION of two DOUBLE PRECISION arguments
  SELECT must be declared EXTERNAL in the calling subroutine.
  If SORT = 'S', SELECT is used to select eigenvalues to sort
  to the top left of the Schur form.
  If SORT = 'N', SELECT is not referenced.
  An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if
  SELECT(WR(j),WI(j)) is true; i.e., if either one of a
  complex conjugate pair of eigenvalues is selected, then both
  are.  Note that a selected complex eigenvalue may no longer
  satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned); in this
  case INFO may be set to N+3 (see INFO below).

 SENSE
  SENSE is CHARACTER*1
```

```
  Determines which reciprocal condition numbers are computed.
  = 'N': None are computed;
  = 'E': Computed for average of selected eigenvalues only;
  = 'V': Computed for selected right invariant subspace only;
  = 'B': Computed for both.
  If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the N-by-N matrix A.
  On exit, A is overwritten by its real Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELECT is true. (Complex conjugate
  pairs for which SELECT is true for either
  eigenvalue count as 2.)

WR
  WR is DOUBLE PRECISION array, dimension (N)

WI
  WI is DOUBLE PRECISION array, dimension (N)
  WR and WI contain the real and imaginary parts, respectively,
  of the computed eigenvalues, in the same order that they
  appear on the diagonal of the output Schur form T.  Complex
  conjugate pairs of eigenvalues appear consecutively with the
  eigenvalue having the positive imaginary part first.

VS
  VS is DOUBLE PRECISION array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1, and if
  JOBVS = 'V', LDVS >= N.

RCONDE
```

```
  RCONDE is DOUBLE PRECISION
  If SENSE = 'E' or 'B', RCONDE contains the reciprocal
  condition number for the average of the selected eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is DOUBLE PRECISION
  If SENSE = 'V' or 'B', RCONDV contains the reciprocal
  condition number for the selected right invariant subspace.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,3*N).
  Also, if SENSE = 'E' or 'V' or 'B',
  LWORK >= N+2*SDIM*(N-SDIM), where SDIM is the number of
  selected eigenvalues computed by this routine.  Note that
  N+2*SDIM*(N-SDIM) <= N+N*N/2. Note also that an error is only
  returned if LWORK < max(1,3*N), but if SENSE = 'E' or 'V' or
  'B' this may not be large enough.
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates upper bounds on the optimal sizes of the
  arrays WORK and IWORK, returns these values as the first
  entries of the WORK and IWORK arrays, and no error messages
  related to LWORK or LIWORK are issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  LIWORK >= 1; if SENSE = 'V' or 'B', LIWORK >= SDIM*(N-SDIM).
  Note that SDIM*(N-SDIM) <= N*N/4. Note also that an error is
  only returned if LIWORK < 1, but if SENSE = 'V' or 'B' this
  may not be large enough.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates upper bounds on the optimal sizes of
  the arrays WORK and IWORK, returns these values as the first
  entries of the WORK and IWORK arrays, and no error messages
  related to LWORK or LIWORK are issued by XERBLA.
```

```
BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0: if INFO = i, and i is
     <= N: the QR algorithm failed to compute all the
           eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI
           contain those eigenvalues which have converged; if
           JOBVS = 'V', VS contains the transformation which
           reduces A to its partially converged Schur form.
     = N+1: the eigenvalues could not be reordered because some
            eigenvalues were too close to separate (the problem
            is very ill-conditioned);
     = N+2: after reordering, roundoff changed values of some
            complex eigenvalues so that leading eigenvalues in
            the Schur form no longer satisfy SELECT=.TRUE.  This
            could also be caused by underflow due to scaling.

SYNOPSIS
   Functions/Subroutines
       subroutine dgeev (JOBVL, JOBVR, N, A, LDA, WR, WI, VL, LDVL, VR, LDVR,
           WORK, LWORK, INFO)
            DGEEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine dgeev (character JOBVL, character JOBVR, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) WR, double precision, dimension( * ) WI, double
       precision, dimension( ldvl, * ) VL, integer LDVL, double precision,
       dimension( ldvr, * ) VR, integer LDVR, double precision, dimension( * )
       WORK, integer LWORK, integer INFO)
        DGEEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   DGEEV computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   The right eigenvector v(j) of A satisfies
   A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
   u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate-transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N': left eigenvectors of A are not computed;
   = 'V': left eigenvectors of A are computed.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N': right eigenvectors of A are not computed;
   = 'V': right eigenvectors of A are computed.

 N
   N is INTEGER
   The order of the matrix A. N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
```

```
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

WR
  WR is DOUBLE PRECISION array, dimension (N)

WI
  WI is DOUBLE PRECISION array, dimension (N)
  WR and WI contain the real and imaginary parts,
  respectively, of the computed eigenvalues.  Complex
  conjugate pairs of eigenvalues appear consecutively
  with the eigenvalue having the positive imaginary part first.

VL
  VL is DOUBLE PRECISION array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  If the j-th eigenvalue is real, then u(j) = VL(:,j),
  the j-th column of VL.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
  u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is DOUBLE PRECISION array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  If the j-th eigenvalue is real, then v(j) = VR(:,j),
  the j-th column of VR.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
  v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1; if
  JOBVR = 'V', LDVR >= N.
```

```
 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,3*N), and
   if JOBVL = 'V' or JOBVR = 'V', LWORK >= 4*N.  For good
   performance, LWORK must generally be larger.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  if INFO = i, the QR algorithm failed to compute all the
         eigenvalues, and no eigenvectors have been computed;
         elements i+1:N of WR and WI contain eigenvalues which
         have converged.

SYNOPSIS
   Functions/Subroutines
       subroutine dgeevx (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, WR, WI, VL,
           LDVL, VR, LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK,
           LWORK, IWORK, INFO)
            DGEEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine dgeevx (character BALANC, character JOBVL, character JOBVR,
       character SENSE, integer N, double precision, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) WR, double precision,

       precision, dimension( * ) RCONDV, double precision, dimension( * )
       WORK, integer LWORK, integer, dimension( * ) IWORK, integer INFO)
        DGEEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   DGEEVX computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   Optionally also, it computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues
   (RCONDE), and reciprocal condition numbers for the right
   eigenvectors (RCONDV).

   The right eigenvector v(j) of A satisfies
            A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
            u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate-transpose of u(j).
```

```
  The computed eigenvectors are normalized to have Euclidean norm
  equal to 1 and largest component real.

  Balancing a matrix means permuting the rows and columns to make it
  more nearly upper triangular, and applying a diagonal similarity
  transformation D * A * D**(-1), where D is a diagonal matrix, to
  make its rows and columns closer in norm and the condition numbers
  of its eigenvalues and eigenvectors smaller.  The computed
  reciprocal condition numbers correspond to the balanced matrix.
  Permuting rows and columns will not change the condition numbers
  (in exact arithmetic) but diagonal scaling will.  For further
  explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Parameters:

 BALANC
  BALANC is CHARACTER*1
  Indicates how the input matrix should be diagonally scaled
  and/or permuted to improve the conditioning of its
  eigenvalues.
  = 'N': Do not diagonally scale or permute;
  = 'P': Perform permutations to make the matrix more nearly
         upper triangular. Do not diagonally scale;
  = 'S': Diagonally scale the matrix, i.e. replace A by
         D*A*D**(-1), where D is a diagonal matrix chosen
         to make the rows and columns of A more equal in
         norm. Do not permute;
  = 'B': Both diagonally scale and permute A.
  Computed reciprocal condition numbers will be for the matrix
  after balancing and/or permuting. Permuting does not change
  condition numbers (in exact arithmetic), but balancing does.

 JOBVL
  JOBVL is CHARACTER*1
  = 'N': left eigenvectors of A are not computed;
  = 'V': left eigenvectors of A are computed.
  If SENSE = 'E' or 'B', JOBVL must = 'V'.

 JOBVR
  JOBVR is CHARACTER*1
  = 'N': right eigenvectors of A are not computed;
  = 'V': right eigenvectors of A are computed.
  If SENSE = 'E' or 'B', JOBVR must = 'V'.

 SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N': None are computed;
  = 'E': Computed for eigenvalues only;
```

```
  = 'V': Computed for right eigenvectors only;
  = 'B': Computed for eigenvalues and right eigenvectors.

  If SENSE = 'E' or 'B', both left and right eigenvectors
  must also be computed (JOBVL = 'V' and JOBVR = 'V').

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten.  If JOBVL = 'V' or
  JOBVR = 'V', A contains the real Schur form of the balanced
  version of the input matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

WR
  WR is DOUBLE PRECISION array, dimension (N)

WI
  WI is DOUBLE PRECISION array, dimension (N)
  WR and WI contain the real and imaginary parts,
  respectively, of the computed eigenvalues.  Complex
  conjugate pairs of eigenvalues will appear consecutively
  with the eigenvalue having the positive imaginary part first.

VL
  VL is DOUBLE PRECISION array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  If the j-th eigenvalue is real, then u(j) = VL(:,j),
  the j-th column of VL.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
  u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is DOUBLE PRECISION array, dimension (LDVR,N)
```

```
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  If the j-th eigenvalue is real, then v(j) = VR(:,j),
  the j-th column of VR.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
  v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1, and if
  JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values determined when A was
  balanced.  The balanced A(i,j) = 0 if I > J and
  J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE
  SCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  when balancing A.  If P(j) is the index of the row and column
  interchanged with row and column j, and D(j) is the scaling
  factor applied to row and column j, then
  SCALE(J) = P(J),    for J = 1,...,ILO-1
           = D(J),    for J = ILO,...,IHI
           = P(J)     for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

ABNRM
  ABNRM is DOUBLE PRECISION
  The one-norm of the balanced matrix (the maximum
  of the sum of absolute values of elements of any column).

RCONDE
  RCONDE is DOUBLE PRECISION array, dimension (N)
  RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV
  RCONDV is DOUBLE PRECISION array, dimension (N)
  RCONDV(j) is the reciprocal condition number of the j-th
  right eigenvector.
```

```
 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.   If SENSE = 'N' or 'E',
   LWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V',
   LWORK >= 3*N.  If SENSE = 'V' or 'B', LWORK >= N*(N+6).
   For good performance, LWORK must generally be larger.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 IWORK
   IWORK is INTEGER array, dimension (2*N-2)
   If SENSE = 'N' or 'E', not referenced.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  if INFO = i, the QR algorithm failed to compute all the
         eigenvalues, and no eigenvectors or condition numbers
         have been computed; elements 1:ILO-1 and i+1:N of WR
         and WI contain eigenvalues which have converged.

SYNOPSIS
   Functions/Subroutines
       subroutine dgges (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
           BWORK, INFO)
            DGGES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine dgges (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, integer N, double precision, dimension( lda, * ) A,
       integer LDA, double precision, dimension( ldb, * ) B, integer LDB,
       integer SDIM, double precision, dimension( * ) ALPHAR, double
       precision, dimension( * ) ALPHAI, double precision, dimension( * )
       BETA, double precision, dimension( ldvsl, * ) VSL, integer LDVSL,
       double precision, dimension( ldvsr, * ) VSR, integer LDVSR, double
       precision, dimension( * ) WORK, integer LWORK, logical, dimension( * )
       BWORK, integer INFO)
        DGGES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   DGGES computes for a pair of N-by-N real nonsymmetric matrices (A,B),
   the generalized eigenvalues, the generalized real Schur form (S,T),
   optionally, the left and/or right matrices of Schur vectors (VSL and
   VSR). This gives the generalized Schur factorization
```

```
          (A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   quasi-triangular matrix S and the upper triangular matrix T.The
   leading columns of VSL and VSR then form an orthonormal basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   DGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or both being zero.

   A pair of matrices (S,T) is in generalized real Schur form if T is
   upper triangular with non-negative diagonal and S is block upper
   triangular with 1-by-1 and 2-by-2 blocks.  1-by-1 blocks correspond
   to real generalized eigenvalues, while 2-by-2 blocks of S will be
   "standardized" by making the corresponding elements of T have the form:
          [  a  0  ]
          [  0  b  ]
   and the pair of corresponding 2-by-2 blocks in S and T will have a
   complex conjugate pair of generalized eigenvalues.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the generalized Schur form.
   = 'N':  Eigenvalues are not ordered;
   = 'S':  Eigenvalues are ordered (see SELCTG);

 SELCTG
   SELCTG is a LOGICAL FUNCTION of three DOUBLE PRECISION arguments
   SELCTG must be declared EXTERNAL in the calling subroutine.
   If SORT = 'N', SELCTG is not referenced.
```

```
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if
  SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either
  one of a complex conjugate pair of eigenvalues is selected,
  then both complex eigenvalues are selected.

  Note that in the ill-conditioned case, a selected complex
  eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),
  BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2
  in this case.

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.  (Complex conjugate pairs for which
  SELCTG is true for either eigenvalue count as 2.)

ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
```

```
  be the generalized eigenvalues.  ALPHAR(j) + ALPHAI(j)*i,
  and  BETA(j),j=1,...,N are the diagonals of the complex Schur
  form (S,T) that would result if the 2-by-2 diagonal blocks of
  the real Schur form of (A,B) were further reduced to
  triangular form using 2-by-2 complex unitary transformations.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio.
  However, ALPHAR and ALPHAI will be always less than and
  usually comparable with norm(A) in magnitude, and BETA always
  less than and usually comparable with norm(B).

VSL
  VSL is DOUBLE PRECISION array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is DOUBLE PRECISION array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N = 0, LWORK >= 1, else LWORK >= 8*N+16.
  For good performance , LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.
```

```
 BWORK
   BWORK is LOGICAL array, dimension (N)
   Not referenced if SORT = 'N'.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  (A,B) are not in Schur
         form, but ALPHAR(j), ALPHAI(j), and BETA(j) should
         be correct for j=INFO+1,...,N.
   > N:
    =N+1: other than QZ iteration failed in DHGEQZ.
    =N+2: after reordering, roundoff changed values of
          some complex eigenvalues so that leading
          eigenvalues in the Generalized Schur form no
          longer satisfy SELCTG=.TRUE.  This could also
          be caused due to scaling.
    =N+3: reordering failed in DTGSEN.
```

```

```
      precision, dimension( * ) WORK, integer LWORK, logical, dimension( * )
      BWORK, integer INFO)
       DGGES3 computes the eigenvalues, the Schur form, and, optionally, the
      matrix of Schur vectors for GE matrices (blocked algorithm)

Purpose:
   DGGES3 computes for a pair of N-by-N real nonsymmetric matrices (A,B),
   the generalized eigenvalues, the generalized real Schur form (S,T),
   optionally, the left and/or right matrices of Schur vectors (VSL and
   VSR). This gives the generalized Schur factorization

        (A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   quasi-triangular matrix S and the upper triangular matrix T.The
   leading columns of VSL and VSR then form an orthonormal basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   DGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or both being zero.

   A pair of matrices (S,T) is in generalized real Schur form if T is
   upper triangular with non-negative diagonal and S is block upper
   triangular with 1-by-1 and 2-by-2 blocks.  1-by-1 blocks correspond
   to real generalized eigenvalues, while 2-by-2 blocks of S will be
   "standardized" by making the corresponding elements of T have the form:
          [  a  0  ]
          [  0  b  ]
   and the pair of corresponding 2-by-2 blocks in S and T will have a
   complex conjugate pair of generalized eigenvalues.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
```

```
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the generalized Schur form.
  = 'N':  Eigenvalues are not ordered;
  = 'S':  Eigenvalues are ordered (see SELCTG);

SELCTG
  SELCTG is a LOGICAL FUNCTION of three DOUBLE PRECISION arguments
  SELCTG must be declared EXTERNAL in the calling subroutine.
  If SORT = 'N', SELCTG is not referenced.
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if
  SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either
  one of a complex conjugate pair of eigenvalues is selected,
  then both complex eigenvalues are selected.

  Note that in the ill-conditioned case, a selected complex
  eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),
  BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2
  in this case.

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.  (Complex conjugate pairs for which
  SELCTG is true for either eigenvalue count as 2.)
```

```
ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  ALPHAR(j) + ALPHAI(j)*i,
  and  BETA(j),j=1,...,N are the diagonals of the complex Schur
  form (S,T) that would result if the 2-by-2 diagonal blocks of
  the real Schur form of (A,B) were further reduced to
  triangular form using 2-by-2 complex unitary transformations.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio.
  However, ALPHAR and ALPHAI will be always less than and
  usually comparable with norm(A) in magnitude, and BETA always
  less than and usually comparable with norm(B).

VSL
  VSL is DOUBLE PRECISION array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is DOUBLE PRECISION array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 BWORK
   BWORK is LOGICAL array, dimension (N)
   Not referenced if SORT = 'N'.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  (A,B) are not in Schur
         form, but ALPHAR(j), ALPHAI(j), and BETA(j) should
         be correct for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in DHGEQZ.
         =N+2: after reordering, roundoff changed values of
               some complex eigenvalues so that leading
               eigenvalues in the Generalized Schur form no
               longer satisfy SELCTG=.TRUE.  This could also
               be caused due to scaling.
        =N+3: reordering failed in DTGSEN.

      dimension( * ) BWORK, integer INFO)
       DGGESX computes the eigenvalues, the Schur form, and, optionally, the
      matrix of Schur vectors for GE matrices

Purpose:
   DGGESX computes for a pair of N-by-N real nonsymmetric matrices
   (A,B), the generalized eigenvalues, the real Schur form (S,T), and,
   optionally, the left and/or right matrices of Schur vectors (VSL and
   VSR).  This gives the generalized Schur factorization

          (A,B) = ( (VSL) S (VSR)**T, (VSL) T (VSR)**T )

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   quasi-triangular matrix S and the upper triangular matrix T; computes
   a reciprocal condition number for the average of the selected
   eigenvalues (RCONDE); and computes a reciprocal condition number for
   the right and left deflating subspaces corresponding to the selected
   eigenvalues (RCONDV). The leading columns of VSL and VSR then form
   an orthonormal basis for the corresponding left and right eigenspaces
   (deflating subspaces).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or for both being zero.

   A pair of matrices (S,T) is in generalized real Schur form if T is
   upper triangular with non-negative diagonal and S is block upper
   triangular with 1-by-1 and 2-by-2 blocks.  1-by-1 blocks correspond
   to real generalized eigenvalues, while 2-by-2 blocks of S will be
   "standardized" by making the corresponding elements of T have the form:
          [  a  0  ]
          [  0  b  ]
   and the pair of corresponding 2-by-2 blocks in S and T will have a
   complex conjugate pair of generalized eigenvalues.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
```

```
  = 'V':  compute the right Schur vectors.

SORT
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the generalized Schur form.
  = 'N':  Eigenvalues are not ordered;
  = 'S':  Eigenvalues are ordered (see SELCTG).

SELCTG
  SELCTG is procedure) LOGICAL FUNCTION of three DOUBLE PRECISION arguments
  SELCTG must be declared EXTERNAL in the calling subroutine.
  If SORT = 'N', SELCTG is not referenced.
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if
  SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either
  one of a complex conjugate pair of eigenvalues is selected,
  then both complex eigenvalues are selected.
  Note that a selected complex eigenvalue may no longer satisfy
  SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering,
  since ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned), in this
  case INFO is set to N+3.

SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N' : None are computed;
  = 'E' : Computed for average of selected eigenvalues only;
  = 'V' : Computed for selected deflating subspaces only;
  = 'B' : Computed for both.
  If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
```

```
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.  (Complex conjugate pairs for which
  SELCTG is true for either eigenvalue count as 2.)

ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  ALPHAR(j) + ALPHAI(j)*i
  and BETA(j),j=1,...,N  are the diagonals of the complex Schur
  form (S,T) that would result if the 2-by-2 diagonal blocks of
  the real Schur form of (A,B) were further reduced to
  triangular form using 2-by-2 complex unitary transformations.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio.
  However, ALPHAR and ALPHAI will be always less than and
  usually comparable with norm(A) in magnitude, and BETA always
  less than and usually comparable with norm(B).

VSL
  VSL is DOUBLE PRECISION array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is DOUBLE PRECISION array, dimension (LDVSR,N)
```

```
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

RCONDE
  RCONDE is DOUBLE PRECISION array, dimension ( 2 )
  If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the
  reciprocal condition numbers for the average of the selected eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is DOUBLE PRECISION array, dimension ( 2 )
  If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the
  reciprocal condition numbers for the selected deflating subspaces.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B',
  LWORK >= max( 8*N, 6*N+16, 2*SDIM*(N-SDIM) ), else
  LWORK >= max( 8*N, 6*N+16 ).
  Note that 2*SDIM*(N-SDIM) <= N*N/2.
  Note also that an error is only returned if
  LWORK < max( 8*N, 6*N+16), but if SENSE = 'E' or 'V' or 'B'
  this may not be large enough.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the bound on the optimal size of the WORK
  array and the minimum size of the IWORK array, returns these
  values as the first entries of the WORK and IWORK arrays, and
  no error message related to LWORK or LIWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise
  LIWORK >= N+6.
```

```
   If LIWORK = -1, then a workspace query is assumed; the
   routine only calculates the bound on the optimal size of the
   WORK array and the minimum size of the IWORK array, returns
   these values as the first entries of the WORK and IWORK
   arrays, and no error message related to LWORK or LIWORK is issued by XERBLA.

 BWORK
   BWORK is LOGICAL array, dimension (N)
   Not referenced if SORT = 'N'.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  (A,B) are not in Schur
         form, but ALPHAR(j), ALPHAI(j), and BETA(j) should
         be correct for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in DHGEQZ
         =N+2: after reordering, roundoff changed values of
               some complex eigenvalues so that leading
               eigenvalues in the Generalized Schur form no
               longer satisfy SELCTG=.TRUE.  This could also
               be caused due to scaling.
         =N+3: reordering failed in DTGSEN.

Further Details:

   An approximate (asymptotic) bound on the average absolute error of
   the selected eigenvalues is

   EPS * norm((A, B)) / RCONDE( 1 ).

   An approximate (asymptotic) bound on the maximum angular error in
   the computed deflating subspaces is

   EPS * norm((A, B)) / RCONDV( 2 ).

SYNOPSIS
   Functions/Subroutines
       subroutine dggev (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI,
           BETA, VL, LDVL, VR, LDVR, WORK, LWORK, INFO)
            DGGEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine dggev (character JOBVL, character JOBVR, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,

        DGGEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   DGGEV computes for a pair of N-by-N real nonsymmetric matrices (A,B)
   the generalized eigenvalues, and optionally, the left and/or right
   generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

           A * v(j) = lambda(j) * B * v(j).

   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

           u(j)**H * A  = lambda(j) * u(j)**H * B .

   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
```

```
  JOBVL is CHARACTER*1
  = 'N':  do not compute the left generalized eigenvectors;
  = 'V':  compute the left generalized eigenvectors.

JOBVR
  JOBVR is CHARACTER*1
  = 'N':  do not compute the right generalized eigenvectors;
  = 'V':  compute the right generalized eigenvectors.

N
  N is INTEGER
  The order of the matrices A, B, VL, and VR.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the matrix A in the pair (A,B).
  On exit, A has been overwritten.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  If ALPHAI(j) is zero, then
  the j-th eigenvalue is real; if positive, then the j-th and
  (j+1)-st eigenvalues are a complex conjugate pair, with
  ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio
  alpha/beta.  However, ALPHAR and ALPHAI will be always less
  than and usually comparable with norm(A) in magnitude, and
```

```
  BETA always less than and usually comparable with norm(B).

VL
  VL is DOUBLE PRECISION array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  u(j) = VL(:,j), the j-th column of VL. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is DOUBLE PRECISION array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  v(j) = VR(:,j), the j-th column of VR. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,8*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  No eigenvectors have been
         calculated, but ALPHAR(j), ALPHAI(j), and BETA(j)
         should be correct for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in DHGEQZ.
         =N+2: error return from DTGEVC.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dggev3 (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI,
           BETA, VL, LDVL, VR, LDVR, WORK, LWORK, INFO)
            DGGEV3 computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices (blocked algorithm)

Function/Subroutine Documentation
   subroutine dggev3 (character JOBVL, character JOBVR, integer N, double
```

```
      precision, dimension( lda, * ) A, integer LDA, double precision,
      dimension( ldb, * ) B, integer LDB, double precision, dimension( * )
      ALPHAR, double precision, dimension( * ) ALPHAI, double precision,
      dimension( * ) BETA, double precision, dimension( ldvl, * ) VL, integer
      LDVL, double precision, dimension( ldvr, * ) VR, integer LDVR, double
      precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DGGEV3 computes the eigenvalues and, optionally, the left and/or right
      eigenvectors for GE matrices (blocked algorithm)

Purpose:
   DGGEV3 computes for a pair of N-by-N real nonsymmetric matrices (A,B)
   the generalized eigenvalues, and optionally, the left and/or right
   generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j).

   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   u(j)**H * A  = lambda(j) * u(j)**H * B .

   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA, N)
```

```
  On entry, the matrix A in the pair (A,B).
  On exit, A has been overwritten.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  If ALPHAI(j) is zero, then
  the j-th eigenvalue is real; if positive, then the j-th and
  (j+1)-st eigenvalues are a complex conjugate pair, with
  ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio
  alpha/beta.  However, ALPHAR and ALPHAI will be always less
  than and usually comparable with norm(A) in magnitude, and
  BETA always less than and usually comparable with norm(B).

VL
  VL is DOUBLE PRECISION array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  u(j) = VL(:,j), the j-th column of VL. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVL = 'N'.

LDVL
```

```
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is DOUBLE PRECISION array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  v(j) = VR(:,j), the j-th column of VR. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  No eigenvectors have been
        calculated, but ALPHAR(j), ALPHAI(j), and BETA(j)
        should be correct for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in DHGEQZ.
        =N+2: error return from DTGEVC.

       logical, dimension( * ) BWORK, integer INFO)
        DGGEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   DGGEVX computes for a pair of N-by-N real nonsymmetric matrices (A,B)
   the generalized eigenvalues, and optionally, the left and/or right
   generalized eigenvectors.

   Optionally also, it computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for
   the eigenvalues (RCONDE), and reciprocal condition numbers for the
   right eigenvectors (RCONDV).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j) .

   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies
```

```
  u(j)**H * A  = lambda(j) * u(j)**H * B.

  where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 BALANC
   BALANC is CHARACTER*1
   Specifies the balance option to be performed.
   = 'N':  do not diagonally scale or permute;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.
   Computed reciprocal condition numbers will be for the
   matrices after permuting and/or balancing. Permuting does
   not change condition numbers (in exact arithmetic), but balancing does.

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': none are computed;
   = 'E': computed for eigenvalues only;
   = 'V': computed for eigenvectors only;
   = 'B': computed for eigenvalues and eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA, N)
   On entry, the matrix A in the pair (A,B).
   On exit, A has been overwritten. If JOBVL='V' or JOBVR='V'
   or both, then A contains the first part of the real Schur
   form of the "balanced" versions of the input A and B.

 LDA
   LDA is INTEGER
   The leading dimension of A.  LDA >= max(1,N).
```

```
B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten. If JOBVL='V' or JOBVR='V'
  or both, then B contains the second part of the real Schur
  form of the "balanced" versions of the input A and B.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  If ALPHAI(j) is zero, then
  the j-th eigenvalue is real; if positive, then the j-th and
  (j+1)-st eigenvalues are a complex conjugate pair, with
  ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio
  ALPHA/BETA. However, ALPHAR and ALPHAI will be always less
  than and usually comparable with norm(A) in magnitude, and
  BETA always less than and usually comparable with norm(B).

VL
  VL is DOUBLE PRECISION array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  u(j) = VL(:,j), the j-th column of VL. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1).
  Each eigenvector will be scaled so the largest component have
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
```

```
  VR is DOUBLE PRECISION array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  v(j) = VR(:,j), the j-th column of VR. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1).
  Each eigenvector will be scaled so the largest component have
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If PL(j) is the index of the
  row interchanged with row j, and DL(j) is the scaling
  factor applied to row j, then
  LSCALE(j) = PL(j)  for j = 1,...,ILO-1
            = DL(j)  for j = ILO,...,IHI
            = PL(j)  for j = IHI+1,...,N.
            The order in which the interchanges are made is N to IHI+1,
            then 1 to ILO-1.

RSCALE
  RSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If PR(j) is the index of the
  column interchanged with column j, and DR(j) is the scaling
  factor applied to column j, then
  RSCALE(j) = PR(j)  for j = 1,...,ILO-1
            = DR(j)  for j = ILO,...,IHI
            = PR(j)  for j = IHI+1,...,N
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.
```

```
ABNRM
  ABNRM is DOUBLE PRECISION
  The one-norm of the balanced matrix A.

BBNRM
  BBNRM is DOUBLE PRECISION
  The one-norm of the balanced matrix B.

RCONDE
  RCONDE is DOUBLE PRECISION array, dimension (N)
  If SENSE = 'E' or 'B', the reciprocal condition numbers of
  the eigenvalues, stored in consecutive elements of the array.
  For a complex conjugate pair of eigenvalues two consecutive
  elements of RCONDE are set to the same value. Thus RCONDE(j),
  RCONDV(j), and the j-th columns of VL and VR all correspond
  to the j-th eigenpair.
  If SENSE = 'N or 'V', RCONDE is not referenced.

RCONDV
  RCONDV is DOUBLE PRECISION array, dimension (N)
  If SENSE = 'V' or 'B', the estimated reciprocal condition
  numbers of the eigenvectors, stored in consecutive elements
  of the array. For a complex eigenvector two consecutive
  elements of RCONDV are set to the same value. If the
  eigenvalues cannot be reordered to compute RCONDV(j),
  RCONDV(j) is set to 0; this can only occur when the true
  value would be very small anyway.
  If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= max(1,2*N).
  If BALANC = 'S' or 'B', or JOBVL = 'V', or JOBVR = 'V',
  LWORK >= max(1,6*N).
  If SENSE = 'E' or 'B', LWORK >= max(1,10*N).
  If SENSE = 'V' or 'B', LWORK >= 2*N*N+8*N+16.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (N+6)
  If SENSE = 'E', IWORK is not referenced.
```

```
 BWORK
   BWORK is LOGICAL array, dimension (N)
   If SENSE = 'N', BWORK is not referenced.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  No eigenvectors have been
         calculated, but ALPHAR(j), ALPHAI(j), and BETA(j)
         should be correct for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in DHGEQZ.
         =N+2: error return from DTGEVC.

Further Details:
   Balancing a matrix pair (A,B) includes, first, permuting rows and
   columns to isolate eigenvalues, second, applying diagonal similarity
   transformation to the rows and columns to make the rows and columns
   as close in norm as possible. The computed reciprocal condition
   numbers correspond to the balanced matrix. Permuting rows and columns
   will not change the condition numbers (in exact arithmetic) but
   diagonal scaling will.  For further explanation of balancing, see
   section 4.11.1.2 of LAPACK Users' Guide.

   An approximate error bound on the chordal distance between the i-th
   computed generalized eigenvalue w and the corresponding exact
   eigenvalue lambda is

   chord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)

   An approximate error bound for the angle between the i-th computed
   eigenvector VL(i) or VR(i) is given by

   EPS * norm(ABNRM, BBNRM) / DIF(i).

   For further explanation of the reciprocal condition numbers RCONDE
   and RCONDV, see section 4.11 of LAPACK User's Guide.

SYNOPSIS
   Functions/Subroutines
       subroutine sgees (JOBVS, SORT, SELECT, N, A, LDA, SDIM, WR, WI, VS,
           LDVS, WORK, LWORK, BWORK, INFO)
            SGEES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine sgees (character JOBVS, character SORT, external SELECT, integer
       N, real, dimension( lda, * ) A, integer LDA, integer SDIM, real,
       dimension( * ) WR, real, dimension( * ) WI, real, dimension( ldvs, * )
       VS, integer LDVS, real, dimension( * ) WORK, integer LWORK, logical,
       dimension( * ) BWORK, integer INFO)
        SGEES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   SGEES computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues, the real Schur form T, and, optionally, the matrix of
   Schur vectors Z.  This gives the Schur factorization A = Z*T*(Z**T).

   Optionally, it also orders the eigenvalues on the diagonal of the
   real Schur form so that selected eigenvalues are at the top left.
   The leading columns of Z then form an orthonormal basis for the
   invariant subspace corresponding to the selected eigenvalues.

   A matrix is in real Schur form if it is upper quasi-triangular with
   1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form
         [  a  b  ]
         [  c  a  ]
   where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Parameters:

 JOBVS
   JOBVS is CHARACTER*1
   = 'N': Schur vectors are not computed;
   = 'V': Schur vectors are computed.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the Schur form.
   = 'N': Eigenvalues are not ordered;
   = 'S': Eigenvalues are ordered (see SELECT).
```

```
SELECT
  SELECT is LOGICAL FUNCTION of two REAL arguments
  SELECT must be declared EXTERNAL in the calling subroutine.
  If SORT = 'S', SELECT is used to select eigenvalues to sort
  to the top left of the Schur form.
  If SORT = 'N', SELECT is not referenced.
  An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if
  SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex
  conjugate pair of eigenvalues is selected, then both complex
  eigenvalues are selected.
  Note that a selected complex eigenvalue may no longer
  satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned); in this
  case INFO is set to N+2 (see INFO below).

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten by its real Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
          for which SELECT is true. (Complex conjugate
          pairs for which SELECT is true for either
          eigenvalue count as 2.)

WR
  WR is REAL array, dimension (N)

WI
  WI is REAL array, dimension (N)
  WR and WI contain the real and imaginary parts,
  respectively, of the computed eigenvalues in the same order
  that they appear on the diagonal of the output Schur form T.
  Complex conjugate pairs of eigenvalues will appear
  consecutively with the eigenvalue having the positive
  imaginary part first.
```

```
VS
  VS is REAL array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1; if
  JOBVS = 'V', LDVS >= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) contains the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,3*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0: if INFO = i, and i is
    <= N: the QR algorithm failed to compute all the
          eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI
          contain those eigenvalues which have converged; if
          JOBVS = 'V', VS contains the matrix which reduces A
          to its partially converged Schur form.
      = N+1: the eigenvalues could not be reordered because some
             eigenvalues were too close to separate (the problem
             is very ill-conditioned);
      = N+2: after reordering, roundoff changed values of some
             complex eigenvalues so that leading eigenvalues in
             the Schur form no longer satisfy SELECT=.TRUE.  This
             could also be caused by underflow due to scaling.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgeesx (JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, WR, WI,
           VS, LDVS, RCONDE, RCONDV, WORK, LWORK, IWORK, LIWORK, BWORK, INFO)
            SGEESX computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine sgeesx (character JOBVS, character SORT, external SELECT,
       character SENSE, integer N, real, dimension( lda, * ) A, integer LDA,
       integer SDIM, real, dimension( * ) WR, real, dimension( * ) WI, real,
       dimension( ldvs, * ) VS, integer LDVS, real RCONDE, real RCONDV, real,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer LIWORK, logical, dimension( * ) BWORK, integer INFO)
        SGEESX computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   SGEESX computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues, the real Schur form T, and, optionally, the matrix of
   Schur vectors Z.  This gives the Schur factorization A = Z*T*(Z**T).

   Optionally, it also orders the eigenvalues on the diagonal of the
   real Schur form so that selected eigenvalues are at the top left;
   computes a reciprocal condition number for the average of the
```

```
  selected eigenvalues (RCONDE); and computes a reciprocal condition
  number for the right invariant subspace corresponding to the
  selected eigenvalues (RCONDV).  The leading columns of Z form an
  orthonormal basis for this invariant subspace.

  For further explanation of the reciprocal condition numbers RCONDE
  and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where
  these quantities are called s and sep respectively).

  A real matrix is in real Schur form if it is upper quasi-triangular
  with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in
  the form
          [  a  b  ]
          [  c  a  ]
  where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

Parameters:

 JOBVS
   JOBVS is CHARACTER*1
   = 'N': Schur vectors are not computed;
   = 'V': Schur vectors are computed.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the Schur form.
   = 'N': Eigenvalues are not ordered;
   = 'S': Eigenvalues are ordered (see SELECT).

 SELECT
   SELECT is procedure) LOGICAL FUNCTION of two REAL arguments
   SELECT must be declared EXTERNAL in the calling subroutine.
   If SORT = 'S', SELECT is used to select eigenvalues to sort
   to the top left of the Schur form.
   If SORT = 'N', SELECT is not referenced.
   An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if
   SELECT(WR(j),WI(j)) is true; i.e., if either one of a
   complex conjugate pair of eigenvalues is selected, then both
   are.  Note that a selected complex eigenvalue may no longer
   satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since
   ordering may change the value of complex eigenvalues
   (especially if the eigenvalue is ill-conditioned); in this
   case INFO may be set to N+3 (see INFO below).

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': None are computed;
   = 'E': Computed for average of selected eigenvalues only;
```

```
  = 'V': Computed for selected right invariant subspace only;
  = 'B': Computed for both.
  If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is REAL array, dimension (LDA, N)
  On entry, the N-by-N matrix A.
  On exit, A is overwritten by its real Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
          for which SELECT is true. (Complex conjugate
          pairs for which SELECT is true for either
          eigenvalue count as 2.)

WR
  WR is REAL array, dimension (N)

WI
  WI is REAL array, dimension (N)
  WR and WI contain the real and imaginary parts, respectively,
  of the computed eigenvalues, in the same order that they
  appear on the diagonal of the output Schur form T.  Complex
  conjugate pairs of eigenvalues appear consecutively with the
  eigenvalue having the positive imaginary part first.

VS
  VS is REAL array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the orthogonal matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1, and if
  JOBVS = 'V', LDVS >= N.

RCONDE
  RCONDE is REAL
  If SENSE = 'E' or 'B', RCONDE contains the reciprocal
  condition number for the average of the selected eigenvalues.
```

```
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is REAL
  If SENSE = 'V' or 'B', RCONDV contains the reciprocal
  condition number for the selected right invariant subspace.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,3*N).
  Also, if SENSE = 'E' or 'V' or 'B',
  LWORK >= N+2*SDIM*(N-SDIM), where SDIM is the number of
  selected eigenvalues computed by this routine.  Note that
  N+2*SDIM*(N-SDIM) <= N+N*N/2. Note also that an error is only
  returned if LWORK < max(1,3*N), but if SENSE = 'E' or 'V' or
  'B' this may not be large enough.
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates upper bounds on the optimal sizes of the
  arrays WORK and IWORK, returns these values as the first
  entries of the WORK and IWORK arrays, and no error messages
  related to LWORK or LIWORK are issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  LIWORK >= 1; if SENSE = 'V' or 'B', LIWORK >= SDIM*(N-SDIM).
  Note that SDIM*(N-SDIM) <= N*N/4. Note also that an error is
  only returned if LIWORK < 1, but if SENSE = 'V' or 'B' this
  may not be large enough.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates upper bounds on the optimal sizes of
  the arrays WORK and IWORK, returns these values as the first
  entries of the WORK and IWORK arrays, and no error messages
  related to LWORK or LIWORK are issued by XERBLA.

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.
```

```
 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value.
   > 0: if INFO = i, and i is
     <= N: the QR algorithm failed to compute all the
           eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI
           contain those eigenvalues which have converged; if
           JOBVS = 'V', VS contains the transformation which
           reduces A to its partially converged Schur form.
        = N+1: the eigenvalues could not be reordered because some
               eigenvalues were too close to separate (the problem
               is very ill-conditioned);
        = N+2: after reordering, roundoff changed values of some
               complex eigenvalues so that leading eigenvalues in
               the Schur form no longer satisfy SELECT=.TRUE.  This
               could also be caused by underflow due to scaling.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine sgeev (JOBVL, JOBVR, N, A, LDA, WR, WI, VL, LDVL, VR, LDVR,
          WORK, LWORK, INFO)
           SGEEV computes the eigenvalues and, optionally, the left and/or
          right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine sgeev (character JOBVL, character JOBVR, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) WR, real,
       dimension( * ) WI, real, dimension( ldvl, * ) VL, integer LDVL, real,
       dimension( ldvr, * ) VR, integer LDVR, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
        SGEEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   SGEEV computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   The right eigenvector v(j) of A satisfies
            A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
            u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate-transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N': left eigenvectors of A are not computed;
   = 'V': left eigenvectors of A are computed.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N': right eigenvectors of A are not computed;
   = 'V': right eigenvectors of A are computed.

 N
   N is INTEGER
   The order of the matrix A. N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.
   On exit, A has been overwritten.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

WR
  WR is REAL array, dimension (N)

WI
  WI is REAL array, dimension (N)
  WR and WI contain the real and imaginary parts,
  respectively, of the computed eigenvalues.  Complex
  conjugate pairs of eigenvalues appear consecutively
  with the eigenvalue having the positive imaginary part first.

VL
  VL is REAL array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  If the j-th eigenvalue is real, then u(j) = VL(:,j),
  the j-th column of VL.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
  u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is REAL array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  If the j-th eigenvalue is real, then v(j) = VR(:,j),
  the j-th column of VR.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
  v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1; if
  JOBVR = 'V', LDVR >= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,3*N), and
   if JOBVL = 'V' or JOBVR = 'V', LWORK >= 4*N.  For good
   performance, LWORK must generally be larger.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  if INFO = i, the QR algorithm failed to compute all the
         eigenvalues, and no eigenvectors have been computed;
         elements i+1:N of WR and WI contain eigenvalues which
         have converged.

SYNOPSIS
   Functions/Subroutines
       subroutine sgeevx (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, WR, WI, VL,
           LDVL, VR, LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK,
           LWORK, IWORK, INFO)
            SGEEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine sgeevx (character BALANC, character JOBVL, character JOBVR,
       character SENSE, integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( * ) WR, real, dimension( * ) WI, real, dimension(
       ldvl, * ) VL, integer LDVL, real, dimension( ldvr, * ) VR, integer
       LDVR, integer ILO, integer IHI, real, dimension( * ) SCALE, real ABNRM,
       real, dimension( * ) RCONDE, real, dimension( * ) RCONDV, real,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer INFO)
        SGEEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   SGEEVX computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   Optionally also, it computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues
   (RCONDE), and reciprocal condition numbers for the right
   eigenvectors (RCONDV).

   The right eigenvector v(j) of A satisfies
      A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
      u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate-transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.
```

```
  Balancing a matrix means permuting the rows and columns to make it
  more nearly upper triangular, and applying a diagonal similarity
  transformation D * A * D**(-1), where D is a diagonal matrix, to
  make its rows and columns closer in norm and the condition numbers
  of its eigenvalues and eigenvectors smaller.  The computed
  reciprocal condition numbers correspond to the balanced matrix.
  Permuting rows and columns will not change the condition numbers
  (in exact arithmetic) but diagonal scaling will.  For further
  explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Parameters:

 BALANC
   BALANC is CHARACTER*1
   Indicates how the input matrix should be diagonally scaled
   and/or permuted to improve the conditioning of its
   eigenvalues.
   = 'N': Do not diagonally scale or permute;
   = 'P': Perform permutations to make the matrix more nearly
          upper triangular. Do not diagonally scale;
   = 'S': Diagonally scale the matrix, i.e. replace A by
          D*A*D**(-1), where D is a diagonal matrix chosen
          to make the rows and columns of A more equal in
          norm. Do not permute;
   = 'B': Both diagonally scale and permute A.

   Computed reciprocal condition numbers will be for the matrix
   after balancing and/or permuting. Permuting does not change
   condition numbers (in exact arithmetic), but balancing does.

 JOBVL
   JOBVL is CHARACTER*1
   = 'N': left eigenvectors of A are not computed;
   = 'V': left eigenvectors of A are computed.
   If SENSE = 'E' or 'B', JOBVL must = 'V'.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N': right eigenvectors of A are not computed;
   = 'V': right eigenvectors of A are computed.
   If SENSE = 'E' or 'B', JOBVR must = 'V'.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': None are computed;
   = 'E': Computed for eigenvalues only;
   = 'V': Computed for right eigenvectors only;
   = 'B': Computed for eigenvalues and right eigenvectors.
```

```
  If SENSE = 'E' or 'B', both left and right eigenvectors
  must also be computed (JOBVL = 'V' and JOBVR = 'V').

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten.  If JOBVL = 'V' or
  JOBVR = 'V', A contains the real Schur form of the balanced
  version of the input matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

WR
  WR is REAL array, dimension (N)

WI
  WI is REAL array, dimension (N)
  WR and WI contain the real and imaginary parts,
  respectively, of the computed eigenvalues.  Complex
  conjugate pairs of eigenvalues will appear consecutively
  with the eigenvalue having the positive imaginary part first.

VL
  VL is REAL array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  If the j-th eigenvalue is real, then u(j) = VL(:,j),
  the j-th column of VL.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
  u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is REAL array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
```

```
  If JOBVR = 'N', VR is not referenced.
  If the j-th eigenvalue is real, then v(j) = VR(:,j),
  the j-th column of VR.
  If the j-th and (j+1)-st eigenvalues form a complex
  conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
  v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1, and if
  JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values determined when A was
  balanced.  The balanced A(i,j) = 0 if I > J and
  J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE
  SCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  when balancing A.  If P(j) is the index of the row and column
  interchanged with row and column j, and D(j) is the scaling
  factor applied to row and column j, then
  SCALE(J) = P(J),    for J = 1,...,ILO-1
           = D(J),    for J = ILO,...,IHI
           = P(J)     for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

ABNRM
  ABNRM is REAL
  The one-norm of the balanced matrix (the maximum
  of the sum of absolute values of elements of any column).

RCONDE
  RCONDE is REAL array, dimension (N)
  RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV
  RCONDV is REAL array, dimension (N)
  RCONDV(j) is the reciprocal condition number of the j-th
  right eigenvector.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
LWORK
  LWORK is INTEGER
  The dimension of the array WORK.   If SENSE = 'N' or 'E',
  LWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V',
  LWORK >= 3*N.  If SENSE = 'V' or 'B', LWORK >= N*(N+6).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (2*N-2)
  If SENSE = 'N' or 'E', not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, the QR algorithm failed to compute all the
        eigenvalues, and no eigenvectors or condition numbers
        have been computed; elements 1:ILO-1 and i+1:N of WR
        and WI contain eigenvalues which have converged.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgges (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
           BWORK, INFO)
            SGGES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine sgges (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( ldb, * ) B, integer LDB, integer SDIM, real,
       dimension( * ) ALPHAR, real, dimension( * ) ALPHAI, real, dimension( *
       ) BETA, real, dimension( ldvsl, * ) VSL, integer LDVSL, real,
       dimension( ldvsr, * ) VSR, integer LDVSR, real, dimension( * ) WORK,
       integer LWORK, logical, dimension( * ) BWORK, integer INFO)
        SGGES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   SGGES computes for a pair of N-by-N real nonsymmetric matrices (A,B),
   the generalized eigenvalues, the generalized real Schur form (S,T),
   optionally, the left and/or right matrices of Schur vectors (VSL and
   VSR). This gives the generalized Schur factorization

   (A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   quasi-triangular matrix S and the upper triangular matrix T.The
   leading columns of VSL and VSR then form an orthonormal basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   SGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or both being zero.

   A pair of matrices (S,T) is in generalized real Schur form if T is
   upper triangular with non-negative diagonal and S is block upper
   triangular with 1-by-1 and 2-by-2 blocks.  1-by-1 blocks correspond
   to real generalized eigenvalues, while 2-by-2 blocks of S will be
   "standardized" by making the corresponding elements of T have the form:
          [  a  0  ]
          [  0  b  ]

   and the pair of corresponding 2-by-2 blocks in S and T will have a
```

```
   complex conjugate pair of generalized eigenvalues.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the generalized Schur form.
   = 'N':  Eigenvalues are not ordered;
   = 'S':  Eigenvalues are ordered (see SELCTG);

 SELCTG
   SELCTG is a LOGICAL FUNCTION of three REAL arguments
   SELCTG must be declared EXTERNAL in the calling subroutine.
   If SORT = 'N', SELCTG is not referenced.
   If SORT = 'S', SELCTG is used to select eigenvalues to sort
   to the top left of the Schur form.
   An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if
   SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either
   one of a complex conjugate pair of eigenvalues is selected,
   then both complex eigenvalues are selected.

   Note that in the ill-conditioned case, a selected complex
   eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),
   BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2
   in this case.

 N
   N is INTEGER
   The order of the matrices A, B, VSL, and VSR.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the first of the pair of matrices.
   On exit, A has been overwritten by its generalized Schur form S.

 LDA
   LDA is INTEGER
   The leading dimension of A.  LDA >= max(1,N).
```

```
B
  B is REAL array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.  (Complex conjugate pairs for which
  SELCTG is true for either eigenvalue count as 2.)

ALPHAR
  ALPHAR is REAL array, dimension (N)

ALPHAI
  ALPHAI is REAL array, dimension (N)

BETA
  BETA is REAL array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  ALPHAR(j) + ALPHAI(j)*i,
  and  BETA(j),j=1,...,N are the diagonals of the complex Schur
  form (S,T) that would result if the 2-by-2 diagonal blocks of
  the real Schur form of (A,B) were further reduced to
  triangular form using 2-by-2 complex unitary transformations.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio.
  However, ALPHAR and ALPHAI will be always less than and
  usually comparable with norm(A) in magnitude, and BETA always
  less than and usually comparable with norm(B).

VSL
  VSL is REAL array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.
```

```
VSR
  VSR is REAL array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N = 0, LWORK >= 1, else LWORK >= max(8*N,6*N+16).
  For good performance , LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  (A,B) are not in Schur
        form, but ALPHAR(j), ALPHAI(j), and BETA(j) should
        be correct for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in SHGEQZ.
        =N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Generalized Schur form no
              longer satisfy SELCTG=.TRUE.  This could also
              be caused due to scaling.
        =N+3: reordering failed in STGSEN.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgges3 (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHAR, ALPHAI, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK,
           BWORK, INFO)
            SGGES3 computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices (blocked algorithm)

Function/Subroutine Documentation
   subroutine sgges3 (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( ldb, * ) B, integer LDB, integer SDIM, real,
       dimension( * ) ALPHAR, real, dimension( * ) ALPHAI, real, dimension( *
       ) BETA, real, dimension( ldvsl, * ) VSL, integer LDVSL, real,
       dimension( ldvsr, * ) VSR, integer LDVSR, real, dimension( * ) WORK,
       integer LWORK, logical, dimension( * ) BWORK, integer INFO)
        SGGES3 computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices (blocked algorithm)

Purpose:
   SGGES3 computes for a pair of N-by-N real nonsymmetric matrices (A,B),
   the generalized eigenvalues, the generalized real Schur form (S,T),
   optionally, the left and/or right matrices of Schur vectors (VSL and
   VSR). This gives the generalized Schur factorization

   (A,B) = ( (VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T )

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   quasi-triangular matrix S and the upper triangular matrix T.The
   leading columns of VSL and VSR then form an orthonormal basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   SGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or both being zero.

   A pair of matrices (S,T) is in generalized real Schur form if T is
   upper triangular with non-negative diagonal and S is block upper
   triangular with 1-by-1 and 2-by-2 blocks.  1-by-1 blocks correspond
   to real generalized eigenvalues, while 2-by-2 blocks of S will be
   "standardized" by making the corresponding elements of T have the form:
          [  a  0  ]
```

```
         [  0  b  ]

  and the pair of corresponding 2-by-2 blocks in S and T will have a
  complex conjugate pair of generalized eigenvalues.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the generalized Schur form.
   = 'N':  Eigenvalues are not ordered;
   = 'S':  Eigenvalues are ordered (see SELCTG);

 SELCTG
   SELCTG is a LOGICAL FUNCTION of three REAL arguments
   SELCTG must be declared EXTERNAL in the calling subroutine.
   If SORT = 'N', SELCTG is not referenced.
   If SORT = 'S', SELCTG is used to select eigenvalues to sort
   to the top left of the Schur form.
   An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if
   SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either
   one of a complex conjugate pair of eigenvalues is selected,
   then both complex eigenvalues are selected.

   Note that in the ill-conditioned case, a selected complex
   eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),
   BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2
   in this case.

 N
   N is INTEGER
   The order of the matrices A, B, VSL, and VSR.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the first of the pair of matrices.
   On exit, A has been overwritten by its generalized Schur form S.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.  (Complex conjugate pairs for which
  SELCTG is true for either eigenvalue count as 2.)

ALPHAR
  ALPHAR is REAL array, dimension (N)

ALPHAI
  ALPHAI is REAL array, dimension (N)

BETA
  BETA is REAL array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  ALPHAR(j) + ALPHAI(j)*i,
  and  BETA(j),j=1,...,N are the diagonals of the complex Schur
  form (S,T) that would result if the 2-by-2 diagonal blocks of
  the real Schur form of (A,B) were further reduced to
  triangular form using 2-by-2 complex unitary transformations.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio.
  However, ALPHAR and ALPHAI will be always less than and
  usually comparable with norm(A) in magnitude, and BETA always
  less than and usually comparable with norm(B).

VSL
  VSL is REAL array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
```

```
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is REAL array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  (A,B) are not in Schur
        form, but ALPHAR(j), ALPHAI(j), and BETA(j) should
        be correct for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in SHGEQZ.
        =N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Generalized Schur form no
              longer satisfy SELCTG=.TRUE.  This could also
              be caused due to scaling.
        =N+3: reordering failed in STGSEN.
```

       dimension( * ) BWORK, integer INFO)
        SGGESX computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   SGGESX computes for a pair of N-by-N real nonsymmetric matrices
   (A,B), the generalized eigenvalues, the real Schur form (S,T), and,
   optionally, the left and/or right matrices of Schur vectors (VSL and
   VSR).  This gives the generalized Schur factorization

   (A,B) = ( (VSL) S (VSR)**T, (VSL) T (VSR)**T )

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   quasi-triangular matrix S and the upper triangular matrix T; computes
   a reciprocal condition number for the average of the selected
   eigenvalues (RCONDE); and computes a reciprocal condition number for
   the right and left deflating subspaces corresponding to the selected
   eigenvalues (RCONDV). The leading columns of VSL and VSR then form
   an orthonormal basis for the corresponding left and right eigenspaces
   (deflating subspaces).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or for both being zero.

   A pair of matrices (S,T) is in generalized real Schur form if T is
   upper triangular with non-negative diagonal and S is block upper
   triangular with 1-by-1 and 2-by-2 blocks.  1-by-1 blocks correspond
   to real generalized eigenvalues, while 2-by-2 blocks of S will be
   "standardized" by making the corresponding elements of T have the form:
          [  a  0  ]
          [  0  b  ]

   and the pair of corresponding 2-by-2 blocks in S and T will have a
   complex conjugate pair of generalized eigenvalues.
```

```
Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the generalized Schur form.
   = 'N':  Eigenvalues are not ordered;
   = 'S':  Eigenvalues are ordered (see SELCTG).

 SELCTG
   SELCTG is procedure) LOGICAL FUNCTION of three REAL arguments
   SELCTG must be declared EXTERNAL in the calling subroutine.
   If SORT = 'N', SELCTG is not referenced.
   If SORT = 'S', SELCTG is used to select eigenvalues to sort
   to the top left of the Schur form.
   An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if
   SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either
   one of a complex conjugate pair of eigenvalues is selected,
   then both complex eigenvalues are selected.
   Note that a selected complex eigenvalue may no longer satisfy
   SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering,
   since ordering may change the value of complex eigenvalues
   (especially if the eigenvalue is ill-conditioned), in this
   case INFO is set to N+3.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N' : None are computed;
   = 'E' : Computed for average of selected eigenvalues only;
   = 'V' : Computed for selected deflating subspaces only;
   = 'B' : Computed for both.
   If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

 N
   N is INTEGER
   The order of the matrices A, B, VSL, and VSR.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
```

```
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.  (Complex conjugate pairs for which
  SELCTG is true for either eigenvalue count as 2.)

ALPHAR
  ALPHAR is REAL array, dimension (N)

ALPHAI
  ALPHAI is REAL array, dimension (N)

BETA
  BETA is REAL array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  ALPHAR(j) + ALPHAI(j)*i
  and BETA(j),j=1,...,N  are the diagonals of the complex Schur
  form (S,T) that would result if the 2-by-2 diagonal blocks of
  the real Schur form of (A,B) were further reduced to
  triangular form using 2-by-2 complex unitary transformations.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio.
  However, ALPHAR and ALPHAI will be always less than and
  usually comparable with norm(A) in magnitude, and BETA always
  less than and usually comparable with norm(B).

VSL
  VSL is REAL array, dimension (LDVSL,N)
```

```
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is REAL array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

RCONDE
  RCONDE is REAL array, dimension ( 2 )
  If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the
  reciprocal condition numbers for the average of the selected
  eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is REAL array, dimension ( 2 )
  If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the
  reciprocal condition numbers for the selected deflating subspaces.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B',
  LWORK >= max( 8*N, 6*N+16, 2*SDIM*(N-SDIM) ), else
  LWORK >= max( 8*N, 6*N+16 ).
  Note that 2*SDIM*(N-SDIM) <= N*N/2.
  Note also that an error is only returned if
  LWORK < max( 8*N, 6*N+16), but if SENSE = 'E' or 'V' or 'B'
  this may not be large enough.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the bound on the optimal size of the WORK
  array and the minimum size of the IWORK array, returns these
  values as the first entries of the WORK and IWORK arrays, and
```

```
   no error message related to LWORK or LIWORK is issued by XERBLA.

 IWORK
   IWORK is INTEGER array, dimension (MAX(1,LIWORK))
   On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

 LIWORK
   LIWORK is INTEGER
   The dimension of the array IWORK.
   If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise
   LIWORK >= N+6.

   If LIWORK = -1, then a workspace query is assumed; the
   routine only calculates the bound on the optimal size of the
   WORK array and the minimum size of the IWORK array, returns
   these values as the first entries of the WORK and IWORK
   arrays, and no error message related to LWORK or LIWORK is
   issued by XERBLA.

 BWORK
   BWORK is LOGICAL array, dimension (N)
   Not referenced if SORT = 'N'.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  (A,B) are not in Schur
         form, but ALPHAR(j), ALPHAI(j), and BETA(j) should
         be correct for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in SHGEQZ
         =N+2: after reordering, roundoff changed values of
               some complex eigenvalues so that leading
               eigenvalues in the Generalized Schur form no
               longer satisfy SELCTG=.TRUE.  This could also
               be caused due to scaling.
         =N+3: reordering failed in STGSEN.

Further Details:
   An approximate (asymptotic) bound on the average absolute error of
   the selected eigenvalues is

   EPS * norm((A, B)) / RCONDE( 1 ).

   An approximate (asymptotic) bound on the maximum angular error in
   the computed deflating subspaces is

   EPS * norm((A, B)) / RCONDV( 2 ).

SYNOPSIS
   Functions/Subroutines
       subroutine sggev (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI,
           BETA, VL, LDVL, VR, LDVR, WORK, LWORK, INFO)
            SGGEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine sggev (character JOBVL, character JOBVR, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( * ) ALPHAR, real, dimension( * ) ALPHAI,
       real, dimension( * ) BETA, real, dimension( ldvl, * ) VL, integer LDVL,
       real, dimension( ldvr, * ) VR, integer LDVR, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
        SGGEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   SGGEV computes for a pair of N-by-N real nonsymmetric matrices (A,B)
   the generalized eigenvalues, and optionally, the left and/or right
   generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j).

   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   u(j)**H * A  = lambda(j) * u(j)**H * B .
```

```
  where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the matrix A in the pair (A,B).
   On exit, A has been overwritten.

 LDA
   LDA is INTEGER
   The leading dimension of A.  LDA >= max(1,N).

 B
   B is REAL array, dimension (LDB, N)
   On entry, the matrix B in the pair (A,B).
   On exit, B has been overwritten.

 LDB
   LDB is INTEGER
   The leading dimension of B.  LDB >= max(1,N).

 ALPHAR
   ALPHAR is REAL array, dimension (N)

 ALPHAI
   ALPHAI is REAL array, dimension (N)

 BETA
   BETA is REAL array, dimension (N)
   On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
   be the generalized eigenvalues.  If ALPHAI(j) is zero, then
   the j-th eigenvalue is real; if positive, then the j-th and
   (j+1)-st eigenvalues are a complex conjugate pair, with
   ALPHAI(j+1) negative.
```

```
  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio
  alpha/beta.  However, ALPHAR and ALPHAI will be always less
  than and usually comparable with norm(A) in magnitude, and
  BETA always less than and usually comparable with norm(B).

VL
  VL is REAL array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  u(j) = VL(:,j), the j-th column of VL. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is REAL array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  v(j) = VR(:,j), the j-th column of VR. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,8*N).
  For good performance, LWORK must generally be larger.
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  No eigenvectors have been
        calculated, but ALPHAR(j), ALPHAI(j), and BETA(j)
        should be correct for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in SHGEQZ.
        =N+2: error return from STGEVC.

SYNOPSIS
   Functions/Subroutines
       subroutine sggev3 (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHAR, ALPHAI,
           BETA, VL, LDVL, VR, LDVR, WORK, LWORK, INFO)
            SGGEV3 computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices (blocked algorithm)
```

```
Function/Subroutine Documentation
   subroutine sggev3 (character JOBVL, character JOBVR, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( * ) ALPHAR, real, dimension( * ) ALPHAI,
       real, dimension( * ) BETA, real, dimension( ldvl, * ) VL, integer LDVL,
       real, dimension( ldvr, * ) VR, integer LDVR, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
        SGGEV3 computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices (blocked algorithm)

Purpose:
   SGGEV3 computes for a pair of N-by-N real nonsymmetric matrices (A,B)
   the generalized eigenvalues, and optionally, the left and/or right
   generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j).

   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   u(j)**H * A  = lambda(j) * u(j)**H * B .

   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.
```

```
A
  A is REAL array, dimension (LDA, N)
  On entry, the matrix A in the pair (A,B).
  On exit, A has been overwritten.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHAR
  ALPHAR is REAL array, dimension (N)

ALPHAI
  ALPHAI is REAL array, dimension (N)

BETA
  BETA is REAL array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  If ALPHAI(j) is zero, then
  the j-th eigenvalue is real; if positive, then the j-th and
  (j+1)-st eigenvalues are a complex conjugate pair, with
  ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio
  alpha/beta.  However, ALPHAR and ALPHAI will be always less
  than and usually comparable with norm(A) in magnitude, and
  BETA always less than and usually comparable with norm(B).

VL
  VL is REAL array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  u(j) = VL(:,j), the j-th column of VL. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVL = 'N'.
```

```
LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is REAL array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  v(j) = VR(:,j), the j-th column of VR. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1).
  Each eigenvector is scaled so the largest component has
  abs(real part)+abs(imag. part)=1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  No eigenvectors have been
        calculated, but ALPHAR(j), ALPHAI(j), and BETA(j)
        should be correct for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in SHGEQZ.
        =N+2: error return from STGEVC.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sggevx (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB,
           ALPHAR, ALPHAI, BETA, VL, LDVL, VR, LDVR, ILO, IHI, LSCALE, RSCALE,
           ABNRM, BBNRM, RCONDE, RCONDV, WORK, LWORK, IWORK, BWORK, INFO)
            SGGEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine sggevx (character BALANC, character JOBVL, character JOBVR,
       character SENSE, integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( ldb, * ) B, integer LDB, real, dimension( * ) ALPHAR,
       real, dimension( * ) ALPHAI, real, dimension( * ) BETA, real,
       dimension( ldvl, * ) VL, integer LDVL, real, dimension( ldvr, * ) VR,
       integer LDVR, integer ILO, integer IHI, real, dimension( * ) LSCALE,
       real, dimension( * ) RSCALE, real ABNRM, real BBNRM, real, dimension( *
       ) RCONDE, real, dimension( * ) RCONDV, real, dimension( * ) WORK,
       integer LWORK, integer, dimension( * ) IWORK, logical, dimension( * )
       BWORK, integer INFO)
        SGGEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   SGGEVX computes for a pair of N-by-N real nonsymmetric matrices (A,B)
   the generalized eigenvalues, and optionally, the left and/or right
   generalized eigenvectors.

   Optionally also, it computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for
```

```
   the eigenvalues (RCONDE), and reciprocal condition numbers for the
   right eigenvectors (RCONDV).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j) .

   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies

   u(j)**H * A  = lambda(j) * u(j)**H * B.

   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 BALANC
   BALANC is CHARACTER*1
   Specifies the balance option to be performed.
   = 'N':  do not diagonally scale or permute;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.
   Computed reciprocal condition numbers will be for the
   matrices after permuting and/or balancing. Permuting does
   not change condition numbers (in exact arithmetic), but
   balancing does.

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': none are computed;
   = 'E': computed for eigenvalues only;
```

```
  = 'V': computed for eigenvectors only;
  = 'B': computed for eigenvalues and eigenvectors.

N
  N is INTEGER
  The order of the matrices A, B, VL, and VR.  N >= 0.

A
  A is REAL array, dimension (LDA, N)
  On entry, the matrix A in the pair (A,B).
  On exit, A has been overwritten. If JOBVL='V' or JOBVR='V'
  or both, then A contains the first part of the real Schur
  form of the "balanced" versions of the input A and B.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten. If JOBVL='V' or JOBVR='V'
  or both, then B contains the second part of the real Schur
  form of the "balanced" versions of the input A and B.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHAR
  ALPHAR is REAL array, dimension (N)

ALPHAI
  ALPHAI is REAL array, dimension (N)

BETA
  BETA is REAL array, dimension (N)
  On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will
  be the generalized eigenvalues.  If ALPHAI(j) is zero, then
  the j-th eigenvalue is real; if positive, then the j-th and
  (j+1)-st eigenvalues are a complex conjugate pair, with
  ALPHAI(j+1) negative.

  Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j)
  may easily over- or underflow, and BETA(j) may even be zero.
  Thus, the user should avoid naively computing the ratio
  ALPHA/BETA. However, ALPHAR and ALPHAI will be always less
  than and usually comparable with norm(A) in magnitude, and
  BETA always less than and usually comparable with norm(B).
```

```
VL
  VL is REAL array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  u(j) = VL(:,j), the j-th column of VL. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1).
  Each eigenvector will be scaled so the largest component have
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is REAL array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order as
  their eigenvalues. If the j-th eigenvalue is real, then
  v(j) = VR(:,j), the j-th column of VR. If the j-th and
  (j+1)-th eigenvalues form a complex conjugate pair, then
  v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1).
  Each eigenvector will be scaled so the largest component have
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If PL(j) is the index of the
  row interchanged with row j, and DL(j) is the scaling
  factor applied to row j, then
```

```
  LSCALE(j) = PL(j)  for j = 1,...,ILO-1
            = DL(j)  for j = ILO,...,IHI
            = PL(j)  for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

RSCALE
  RSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If PR(j) is the index of the
  column interchanged with column j, and DR(j) is the scaling
  factor applied to column j, then
  RSCALE(j) = PR(j)  for j = 1,...,ILO-1
            = DR(j)  for j = ILO,...,IHI
            = PR(j)  for j = IHI+1,...,N
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

ABNRM
  ABNRM is REAL
  The one-norm of the balanced matrix A.

BBNRM
  BBNRM is REAL
  The one-norm of the balanced matrix B.

RCONDE
  RCONDE is REAL array, dimension (N)
  If SENSE = 'E' or 'B', the reciprocal condition numbers of
  the eigenvalues, stored in consecutive elements of the array.
  For a complex conjugate pair of eigenvalues two consecutive
  elements of RCONDE are set to the same value. Thus RCONDE(j),
  RCONDV(j), and the j-th columns of VL and VR all correspond
  to the j-th eigenpair.
  If SENSE = 'N' or 'V', RCONDE is not referenced.

RCONDV
  RCONDV is REAL array, dimension (N)
  If SENSE = 'V' or 'B', the estimated reciprocal condition
  numbers of the eigenvectors, stored in consecutive elements
  of the array. For a complex eigenvector two consecutive
  elements of RCONDV are set to the same value. If the
  eigenvalues cannot be reordered to compute RCONDV(j),
  RCONDV(j) is set to 0; this can only occur when the true
  value would be very small anyway.
  If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK >= max(1,2*N).
   If BALANC = 'S' or 'B', or JOBVL = 'V', or JOBVR = 'V',
   LWORK >= max(1,6*N).
   If SENSE = 'E', LWORK >= max(1,10*N).
   If SENSE = 'V' or 'B', LWORK >= 2*N*N+8*N+16.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 IWORK
   IWORK is INTEGER array, dimension (N+6)
   If SENSE = 'E', IWORK is not referenced.

 BWORK
   BWORK is LOGICAL array, dimension (N)
   If SENSE = 'N', BWORK is not referenced.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   = 1,...,N:
         The QZ iteration failed.  No eigenvectors have been
         calculated, but ALPHAR(j), ALPHAI(j), and BETA(j)
         should be correct for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in SHGEQZ.
         =N+2: error return from STGEVC.

Further Details:
   Balancing a matrix pair (A,B) includes, first, permuting rows and
   columns to isolate eigenvalues, second, applying diagonal similarity
   transformation to the rows and columns to make the rows and columns
   as close in norm as possible. The computed reciprocal condition
   numbers correspond to the balanced matrix. Permuting rows and columns
   will not change the condition numbers (in exact arithmetic) but
   diagonal scaling will.  For further explanation of balancing, see
   section 4.11.1.2 of LAPACK Users' Guide.

   An approximate error bound on the chordal distance between the i-th
   computed generalized eigenvalue w and the corresponding exact
   eigenvalue lambda is

   chord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)

   An approximate error bound for the angle between the i-th computed
```

```
eigenvector VL(i) or VR(i) is given by

EPS * norm(ABNRM, BBNRM) / DIF(i).

For further explanation of the reciprocal condition numbers RCONDE
and RCONDV, see section 4.11 of LAPACK User's Guide.

SYNOPSIS
   Functions/Subroutines
       subroutine cgees (JOBVS, SORT, SELECT, N, A, LDA, SDIM, W, VS, LDVS,
           WORK, LWORK, RWORK, BWORK, INFO)
            CGEES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine cgees (character JOBVS, character SORT, external SELECT, integer
       N, complex, dimension( lda, * ) A, integer LDA, integer SDIM, complex,
       dimension( * ) W, complex, dimension( ldvs, * ) VS, integer LDVS,
       complex, dimension( * ) WORK, integer LWORK, real, dimension( * )
       RWORK, logical, dimension( * ) BWORK, integer INFO)
        CGEES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   CGEES computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues, the Schur form T, and, optionally, the matrix of Schur
   vectors Z.  This gives the Schur factorization A = Z*T*(Z**H).

   Optionally, it also orders the eigenvalues on the diagonal of the
   Schur form so that selected eigenvalues are at the top left.
   The leading columns of Z then form an orthonormal basis for the
   invariant subspace corresponding to the selected eigenvalues.

   A complex matrix is in Schur form if it is upper triangular.

Parameters:

 JOBVS
   JOBVS is CHARACTER*1
   = 'N': Schur vectors are not computed;
   = 'V': Schur vectors are computed.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the Schur form.
   = 'N': Eigenvalues are not ordered:
   = 'S': Eigenvalues are ordered (see SELECT).

 SELECT
   SELECT is a LOGICAL FUNCTION of one COMPLEX argument
   SELECT must be declared EXTERNAL in the calling subroutine.
```

```
  If SORT = 'S', SELECT is used to select eigenvalues to order
  to the top left of the Schur form.
  IF SORT = 'N', SELECT is not referenced.
  The eigenvalue W(j) is selected if SELECT(W(j)) is true.

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten by its Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues for which
                 SELECT is true.

W
  W is COMPLEX array, dimension (N)
  W contains the computed eigenvalues, in the same order that
  they appear on the diagonal of the output Schur form T.

VS
  VS is COMPLEX array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1; if
  JOBVS = 'V', LDVS >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
```

```
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (N)

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0: if INFO = i, and i is
       <= N:  the QR algorithm failed to compute all the
              eigenvalues; elements 1:ILO-1 and i+1:N of W
              contain those eigenvalues which have converged;
              if JOBVS = 'V', VS contains the matrix which
              reduces A to its partially converged Schur form.
       = N+1: the eigenvalues could not be reordered because
              some eigenvalues were too close to separate (the
              problem is very ill-conditioned);
       = N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Schur form no longer satisfy
              SELECT = .TRUE..  This could also be caused by
              underflow due to scaling.
```

   subroutine cgeesx (character JOBVS, character SORT, external SELECT,
       character SENSE, integer N, complex, dimension( lda, * ) A, integer
       LDA, integer SDIM, complex, dimension( * ) W, complex, dimension( ldvs,
       * ) VS, integer LDVS, real RCONDE, real RCONDV, complex, dimension( * )
       WORK, integer LWORK, real, dimension( * ) RWORK, logical, dimension( *
       ) BWORK, integer INFO)
        CGEESX computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   CGEESX computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues, the Schur form T, and, optionally, the matrix of Schur
   vectors Z.  This gives the Schur factorization A = Z*T*(Z**H).

   Optionally, it also orders the eigenvalues on the diagonal of the
   Schur form so that selected eigenvalues are at the top left;
   computes a reciprocal condition number for the average of the
   selected eigenvalues (RCONDE); and computes a reciprocal condition
   number for the right invariant subspace corresponding to the
   selected eigenvalues (RCONDV).  The leading columns of Z form an
   orthonormal basis for this invariant subspace.

   For further explanation of the reciprocal condition numbers RCONDE
   and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where
   these quantities are called s and sep respectively).

   A complex matrix is in Schur form if it is upper triangular.

Parameters:
```

```
JOBVS
  JOBVS is CHARACTER*1
  = 'N': Schur vectors are not computed;
  = 'V': Schur vectors are computed.

SORT
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the Schur form.
  = 'N': Eigenvalues are not ordered;
  = 'S': Eigenvalues are ordered (see SELECT).

SELECT
  SELECT is procedure) LOGICAL FUNCTION of one COMPLEX argument
  SELECT must be declared EXTERNAL in the calling subroutine.
  If SORT = 'S', SELECT is used to select eigenvalues to order
  to the top left of the Schur form.
  If SORT = 'N', SELECT is not referenced.
  An eigenvalue W(j) is selected if SELECT(W(j)) is true.

SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N': None are computed;
  = 'E': Computed for average of selected eigenvalues only;
  = 'V': Computed for selected right invariant subspace only;
  = 'B': Computed for both.
  If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is COMPLEX array, dimension (LDA, N)
  On entry, the N-by-N matrix A.
  On exit, A is overwritten by its Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

W
  W is COMPLEX array, dimension (N)
```

```
  W contains the computed eigenvalues, in the same order
  that they appear on the diagonal of the output Schur form T.

VS
  VS is COMPLEX array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1, and if
  JOBVS = 'V', LDVS >= N.

RCONDE
  RCONDE is REAL
  If SENSE = 'E' or 'B', RCONDE contains the reciprocal
  condition number for the average of the selected eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is REAL
  If SENSE = 'V' or 'B', RCONDV contains the reciprocal
  condition number for the selected right invariant subspace.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  Also, if SENSE = 'E' or 'V' or 'B', LWORK >= 2*SDIM*(N-SDIM),
  where SDIM is the number of selected eigenvalues computed by
  this routine.  Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also
  that an error is only returned if LWORK < max(1,2*N), but if
  SENSE = 'E' or 'V' or 'B' this may not be large enough.
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates upper bound on the optimal size of the
  array WORK, returns this value as the first entry of the WORK
  array, and no error message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (N)

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.
```

```
 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value.
   > 0: if INFO = i, and i is
        <= N: the QR algorithm failed to compute all the
              eigenvalues; elements 1:ILO-1 and i+1:N of W
              contain those eigenvalues which have converged; if
              JOBVS = 'V', VS contains the transformation which
              reduces A to its partially converged Schur form.
        = N+1: the eigenvalues could not be reordered because some
               eigenvalues were too close to separate (the problem
               is very ill-conditioned);
        = N+2: after reordering, roundoff changed values of some
               complex eigenvalues so that leading eigenvalues in
               the Schur form no longer satisfy SELECT=.TRUE.  This
               could also be caused by underflow due to scaling.

SYNOPSIS
   Functions/Subroutines
       subroutine cgeev (JOBVL, JOBVR, N, A, LDA, W, VL, LDVL, VR, LDVR, WORK,
           LWORK, RWORK, INFO)
            CGEEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine cgeev (character JOBVL, character JOBVR, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( * ) W, complex,
```

```
      dimension( ldvl, * ) VL, integer LDVL, complex, dimension( ldvr, * )
      VR, integer LDVR, complex, dimension( * ) WORK, integer LWORK, real,
      dimension( * ) RWORK, integer INFO)
       CGEEV computes the eigenvalues and, optionally, the left and/or right
      eigenvectors for GE matrices

Purpose:
   CGEEV computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   The right eigenvector v(j) of A satisfies
      A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.

   The left eigenvector u(j) of A satisfies
      u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N': left eigenvectors of A are not computed;
   = 'V': left eigenvectors of are computed.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N': right eigenvectors of A are not computed;
   = 'V': right eigenvectors of A are computed.

 N
   N is INTEGER
   The order of the matrix A. N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.
   On exit, A has been overwritten.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 W
   W is COMPLEX array, dimension (N)
   W contains the computed eigenvalues.
```

```
VL
  VL is COMPLEX array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  u(j) = VL(:,j), the j-th column of VL.

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  v(j) = VR(:,j), the j-th column of VR.

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1; if
  JOBVR = 'V', LDVR >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, the QR algorithm failed to compute all the
        eigenvalues, and no eigenvectors have been computed;
        elements and i+1:N of W contain eigenvalues which have converged.

*
*     Compute workspace
*      (Note: Comments in the code beginning "Workspace:" describe the
*       minimal amount of workspace needed at that point in the code,
*       as well as the preferred amount for good performance.
*       CWorkspace refers to complex workspace, and RWorkspace to real
*       workspace. NB refers to the optimal block size for the
*       immediately following subroutine, as returned by ILAENV.
*       HSWORK refers to the workspace preferred by CHSEQR, as
*       calculated below. HSWORK is computed assuming ILO=1 and IHI=N,
*       the worst case.)

SYNOPSIS
   Functions/Subroutines
       subroutine cgeevx (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, W, VL, LDVL,
```

```
          VR, LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK, LWORK,
          RWORK, INFO)
           CGEEVX computes the eigenvalues and, optionally, the left and/or
          right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine cgeevx (character BALANC, character JOBVL, character JOBVR,
       character SENSE, integer N, complex, dimension( lda, * ) A, integer
       LDA, complex, dimension( * ) W, complex, dimension( ldvl, * ) VL,
       integer LDVL, complex, dimension( ldvr, * ) VR, integer LDVR, integer
       ILO, integer IHI, real, dimension( * ) SCALE, real ABNRM, real,
       dimension( * ) RCONDE, real, dimension( * ) RCONDV, complex, dimension(
       * ) WORK, integer LWORK, real, dimension( * ) RWORK, integer INFO)
        CGEEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   CGEEVX computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   Optionally also, it computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues
   (RCONDE), and reciprocal condition numbers for the right
   eigenvectors (RCONDV).

   The right eigenvector v(j) of A satisfies
       A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.

   The left eigenvector u(j) of A satisfies
       u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.

   Balancing a matrix means permuting the rows and columns to make it
   more nearly upper triangular, and applying a diagonal similarity
   transformation D * A * D**(-1), where D is a diagonal matrix, to
   make its rows and columns closer in norm and the condition numbers
   of its eigenvalues and eigenvectors smaller.  The computed
   reciprocal condition numbers correspond to the balanced matrix.
   Permuting rows and columns will not change the condition numbers
   (in exact arithmetic) but diagonal scaling will.  For further
   explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Parameters:

 BALANC
```

```
  BALANC is CHARACTER*1
  Indicates how the input matrix should be diagonally scaled
  and/or permuted to improve the conditioning of its eigenvalues.
  = 'N': Do not diagonally scale or permute;
  = 'P': Perform permutations to make the matrix more nearly
         upper triangular. Do not diagonally scale;
  = 'S': Diagonally scale the matrix, ie. replace A by
         D*A*D**(-1), where D is a diagonal matrix chosen
         to make the rows and columns of A more equal in
         norm. Do not permute;
  = 'B': Both diagonally scale and permute A.

  Computed reciprocal condition numbers will be for the matrix
  after balancing and/or permuting. Permuting does not change
  condition numbers (in exact arithmetic), but balancing does.

JOBVL
  JOBVL is CHARACTER*1
  = 'N': left eigenvectors of A are not computed;
  = 'V': left eigenvectors of A are computed.
  If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR
  JOBVR is CHARACTER*1
  = 'N': right eigenvectors of A are not computed;
  = 'V': right eigenvectors of A are computed.
  If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N': None are computed;
  = 'E': Computed for eigenvalues only;
  = 'V': Computed for right eigenvectors only;
  = 'B': Computed for eigenvalues and right eigenvectors.

  If SENSE = 'E' or 'B', both left and right eigenvectors
  must also be computed (JOBVL = 'V' and JOBVR = 'V').

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten.  If JOBVL = 'V' or
  JOBVR = 'V', A contains the Schur form of the balanced
  version of the matrix A.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

W
  W is COMPLEX array, dimension (N)
  W contains the computed eigenvalues.

VL
  VL is COMPLEX array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  u(j) = VL(:,j), the j-th column of VL.

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  v(j) = VR(:,j), the j-th column of VR.

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1; if
  JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values determined when A was
  balanced.  The balanced A(i,j) = 0 if I > J and
  J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE
  SCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  when balancing A.  If P(j) is the index of the row and column
  interchanged with row and column j, and D(j) is the scaling
  factor applied to row and column j, then
  SCALE(J) = P(J),    for J = 1,...,ILO-1
```

```
          = D(J),    for J = ILO,...,IHI
          = P(J)     for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

ABNRM
  ABNRM is REAL
  The one-norm of the balanced matrix (the maximum
  of the sum of absolute values of elements of any column).

RCONDE
  RCONDE is REAL array, dimension (N)
  RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV
  RCONDV is REAL array, dimension (N)
  RCONDV(j) is the reciprocal condition number of the j-th
  right eigenvector.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  If SENSE = 'N' or 'E',
  LWORK >= max(1,2*N), and if SENSE = 'V' or 'B',
  LWORK >= N*N+2*N.
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, the QR algorithm failed to compute all the
        eigenvalues, and no eigenvectors or condition numbers
        have been computed; elements 1:ILO-1 and i+1:N of W
        contain eigenvalues which have converged.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgges (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK,
```

```
          BWORK, INFO)
           CGGES computes the eigenvalues, the Schur form, and, optionally,
          the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine cgges (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, integer N, complex, dimension( lda, * ) A, integer
       LDA, complex, dimension( ldb, * ) B, integer LDB, integer SDIM,
       complex, dimension( * ) ALPHA, complex, dimension( * ) BETA, complex,
       dimension( ldvsl, * ) VSL, integer LDVSL, complex, dimension( ldvsr, *
       ) VSR, integer LDVSR, complex, dimension( * ) WORK, integer LWORK,
       real, dimension( * ) RWORK, logical, dimension( * ) BWORK, integer
       INFO)
        CGGES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   CGGES computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, the generalized complex Schur
   form (S, T), and optionally left and/or right Schur vectors (VSL
   and VSR). This gives the generalized Schur factorization

      (A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )

   where (VSR)**H is the conjugate-transpose of VSR.

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   triangular matrix S and the upper triangular matrix T. The leading
   columns of VSL and VSR then form an unitary basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   CGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0, and even for both being zero.

   A pair of matrices (S,T) is in generalized complex Schur form if S
   and T are upper triangular and, in addition, the diagonal elements
   of T are non-negative real numbers.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.
```

```
JOBVSR
  JOBVSR is CHARACTER*1
  = 'N':  do not compute the right Schur vectors;
  = 'V':  compute the right Schur vectors.

SORT
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the generalized Schur form.
  = 'N':  Eigenvalues are not ordered;
  = 'S':  Eigenvalues are ordered (see SELCTG).

SELCTG
  SELCTG is a LOGICAL FUNCTION of two COMPLEX arguments
  SELCTG must be declared EXTERNAL in the calling subroutine.
  If SORT = 'N', SELCTG is not referenced.
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  An eigenvalue ALPHA(j)/BETA(j) is selected if
  SELCTG(ALPHA(j),BETA(j)) is true.

  Note that a selected complex eigenvalue may no longer satisfy
  SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned), in this
  case INFO is set to N+2 (See INFO below).

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is COMPLEX array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).
```

```
SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.

ALPHA
  ALPHA is COMPLEX array, dimension (N)

BETA
  BETA is COMPLEX array, dimension (N)
  On exit,  ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.  ALPHA(j), j=1,...,N  and  BETA(j),
  j=1,...,N  are the diagonals of the complex Schur form (A,B)
  output by CGGES. The  BETA(j) will be non-negative real.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VSL
  VSL is COMPLEX array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >= 1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is COMPLEX array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
```

```
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (8*N)

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  =1,...,N:
     The QZ iteration failed.  (A,B) are not in Schur
     form, but ALPHA(j) and BETA(j) should be correct for
     j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in CHGEQZ
        =N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Generalized Schur form no
              longer satisfy SELCTG=.TRUE.  This could also
              be caused due to scaling.
        =N+3: reordering failed in CTGSEN.

SYNOPSIS
   Functions/Subroutines
       subroutine cgges3 (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK,
           BWORK, INFO)
            CGGES3 computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices (blocked algorithm)

Function/Subroutine Documentation
   subroutine cgges3 (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, integer N, complex, dimension( lda, * ) A, integer
       LDA, complex, dimension( ldb, * ) B, integer LDB, integer SDIM,
       complex, dimension( * ) ALPHA, complex, dimension( * ) BETA, complex,
       dimension( ldvsl, * ) VSL, integer LDVSL, complex, dimension( ldvsr, *
       ) VSR, integer LDVSR, complex, dimension( * ) WORK, integer LWORK,
       real, dimension( * ) RWORK, logical, dimension( * ) BWORK, integer
       INFO)
        CGGES3 computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices (blocked algorithm)

Purpose:
   CGGES3 computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, the generalized complex Schur
   form (S, T), and optionally left and/or right Schur vectors (VSL
   and VSR). This gives the generalized Schur factorization

      (A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )

   where (VSR)**H is the conjugate-transpose of VSR.
```

```
   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   triangular matrix S and the upper triangular matrix T. The leading
   columns of VSL and VSR then form an unitary basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   CGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0, and even for both being zero.

   A pair of matrices (S,T) is in generalized complex Schur form if S
   and T are upper triangular and, in addition, the diagonal elements
   of T are non-negative real numbers.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the generalized Schur form.
   = 'N':  Eigenvalues are not ordered;
   = 'S':  Eigenvalues are ordered (see SELCTG).

 SELCTG
   SELCTG is a LOGICAL FUNCTION of two COMPLEX arguments
   SELCTG must be declared EXTERNAL in the calling subroutine.
   If SORT = 'N', SELCTG is not referenced.
   If SORT = 'S', SELCTG is used to select eigenvalues to sort
   to the top left of the Schur form.
   An eigenvalue ALPHA(j)/BETA(j) is selected if
   SELCTG(ALPHA(j),BETA(j)) is true.

   Note that a selected complex eigenvalue may no longer satisfy
   SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since
   ordering may change the value of complex eigenvalues
   (especially if the eigenvalue is ill-conditioned), in this
```

```
  case INFO is set to N+2 (See INFO below).

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is COMPLEX array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.

ALPHA
  ALPHA is COMPLEX array, dimension (N)

BETA
  BETA is COMPLEX array, dimension (N)
  On exit,  ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.  ALPHA(j), j=1,...,N  and  BETA(j),
  j=1,...,N  are the diagonals of the complex Schur form (A,B)
  output by CGGES3. The  BETA(j) will be non-negative real.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VSL
  VSL is COMPLEX array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
```

```
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >= 1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is COMPLEX array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (8*N)

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  =1,...,N:
        The QZ iteration failed.  (A,B) are not in Schur
        form, but ALPHA(j) and BETA(j) should be correct for
        j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in CHGEQZ
        =N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Generalized Schur form no
              longer satisfy SELCTG=.TRUE.  This could also
```

```
            be caused due to scaling.
        =N+3: reordering failed in CTGSEN.
```

   subroutine cggesx (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, character SENSE, integer N, complex, dimension( lda, *
       ) A, integer LDA, complex, dimension( ldb, * ) B, integer LDB, integer
       SDIM, complex, dimension( * ) ALPHA, complex, dimension( * ) BETA,
       complex, dimension( ldvsl, * ) VSL, integer LDVSL, complex, dimension(
       ldvsr, * ) VSR, integer LDVSR, real, dimension( 2 ) RCONDE, real,
       dimension( 2 ) RCONDV, complex, dimension( * ) WORK, integer LWORK,
       real, dimension( * ) RWORK, integer, dimension( * ) IWORK, integer
       LIWORK, logical, dimension( * ) BWORK, integer INFO)
        CGGESX computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   CGGESX computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, the complex Schur form (S,T),
   and, optionally, the left and/or right matrices of Schur vectors (VSL
   and VSR).  This gives the generalized Schur factorization

     (A,B) = ( (VSL) S (VSR)**H, (VSL) T (VSR)**H )

   where (VSR)**H is the conjugate-transpose of VSR.

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   triangular matrix S and the upper triangular matrix T; computes
   a reciprocal condition number for the average of the selected
   eigenvalues (RCONDE); and computes a reciprocal condition number for
   the right and left deflating subspaces corresponding to the selected
   eigenvalues (RCONDV). The leading columns of VSL and VSR then form
   an orthonormal basis for the corresponding left and right eigenspaces
   (deflating subspaces).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or for both being zero.

   A pair of matrices (S,T) is in generalized complex Schur form if T is
   upper triangular with non-negative diagonal and S is upper
   triangular.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
```

```
  JOBVSR is CHARACTER*1
  = 'N':  do not compute the right Schur vectors;
  = 'V':  compute the right Schur vectors.

SORT
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the generalized Schur form.
  = 'N':  Eigenvalues are not ordered;
  = 'S':  Eigenvalues are ordered (see SELCTG).

SELCTG
  SELCTG is procedure) LOGICAL FUNCTION of two COMPLEX arguments
  SELCTG must be declared EXTERNAL in the calling subroutine.
  If SORT = 'N', SELCTG is not referenced.
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  Note that a selected complex eigenvalue may no longer satisfy
  SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned), in this
  case INFO is set to N+3 see INFO below).

SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N' : None are computed;
  = 'E' : Computed for average of selected eigenvalues only;
  = 'V' : Computed for selected deflating subspaces only;
  = 'B' : Computed for both.
  If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is COMPLEX array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.
```

```
LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.

ALPHA
  ALPHA is COMPLEX array, dimension (N)

BETA
  BETA is COMPLEX array, dimension (N)
  On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.  ALPHA(j) and BETA(j),j=1,...,N  are
  the diagonals of the complex Schur form (S,T).  BETA(j) will
  be non-negative real.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VSL
  VSL is COMPLEX array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is COMPLEX array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

RCONDE
  RCONDE is REAL array, dimension ( 2 )
  If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the
```

```
  reciprocal condition numbers for the average of the selected
  eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is REAL array, dimension ( 2 )
  If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the
  reciprocal condition number for the selected deflating
  subspaces.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B',
  LWORK >= MAX(1,2*N,2*SDIM*(N-SDIM)), else
  LWORK >= MAX(1,2*N).  Note that 2*SDIM*(N-SDIM) <= N*N/2.
  Note also that an error is only returned if
  LWORK < MAX(1,2*N), but if SENSE = 'E' or 'V' or 'B' this may
  not be large enough.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the bound on the optimal size of the WORK
  array and the minimum size of the IWORK array, returns these
  values as the first entries of the WORK and IWORK arrays, and
  no error message related to LWORK or LIWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension ( 8*N )
  Real workspace.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array WORK.
  If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise
  LIWORK >= N+2.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the bound on the optimal size of the
  WORK array and the minimum size of the IWORK array, returns
  these values as the first entries of the WORK and IWORK
  arrays, and no error message related to LWORK or LIWORK is
```

```
  issued by XERBLA.

 BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
              The QZ iteration failed.  (A,B) are not in Schur
              form, but ALPHA(j) and BETA(j) should be correct for
              j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in CHGEQZ
        =N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Generalized Schur form no
              longer satisfy SELCTG=.TRUE.  This could also
              be caused due to scaling.
        =N+3: reordering failed in CTGSEN.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cggev (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL,
           LDVL, VR, LDVR, WORK, LWORK, RWORK, INFO)
            CGGEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine cggev (character JOBVL, character JOBVR, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldb, * ) B,
       integer LDB, complex, dimension( * ) ALPHA, complex, dimension( * )
       BETA, complex, dimension( ldvl, * ) VL, integer LDVL, complex,
       dimension( ldvr, * ) VR, integer LDVR, complex, dimension( * ) WORK,
       integer LWORK, real, dimension( * ) RWORK, integer INFO)
        CGGEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   CGGEV computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, and optionally, the left and/or
   right generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.
```

```
   The right generalized eigenvector v(j) corresponding to the
   generalized eigenvalue lambda(j) of (A,B) satisfies

      A * v(j) = lambda(j) * B * v(j).

   The left generalized eigenvector u(j) corresponding to the
   generalized eigenvalues lambda(j) of (A,B) satisfies

      u(j)**H * A = lambda(j) * u(j)**H * B

   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA, N)
   On entry, the matrix A in the pair (A,B).
   On exit, A has been overwritten.

 LDA
   LDA is INTEGER
   The leading dimension of A.  LDA >= max(1,N).

 B
   B is COMPLEX array, dimension (LDB, N)
   On entry, the matrix B in the pair (A,B).
   On exit, B has been overwritten.

 LDB
   LDB is INTEGER
   The leading dimension of B.  LDB >= max(1,N).

 ALPHA
   ALPHA is COMPLEX array, dimension (N)

 BETA
```

```
  BETA is COMPLEX array, dimension (N)
  On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VL
  VL is COMPLEX array, dimension (LDVL,N)
  If JOBVL = 'V', the left generalized eigenvectors u(j) are
  stored one after another in the columns of VL, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX array, dimension (LDVR,N)
  If JOBVR = 'V', the right generalized eigenvectors v(j) are
  stored one after another in the columns of VR, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
```

```
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (8*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  =1,...,N:
        The QZ iteration failed.  No eigenvectors have been
        calculated, but ALPHA(j) and BETA(j) should be
        correct for j=INFO+1,...,N.
  > N:  =N+1: other then QZ iteration failed in SHGEQZ,
        =N+2: error return from STGEVC.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cggev3 (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL,
           LDVL, VR, LDVR, WORK, LWORK, RWORK, INFO)
            CGGEV3 computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices (blocked algorithm)

Function/Subroutine Documentation
   subroutine cggev3 (character JOBVL, character JOBVR, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldb, * ) B,
       integer LDB, complex, dimension( * ) ALPHA, complex, dimension( * )
       BETA, complex, dimension( ldvl, * ) VL, integer LDVL, complex,
       dimension( ldvr, * ) VR, integer LDVR, complex, dimension( * ) WORK,
       integer LWORK, real, dimension( * ) RWORK, integer INFO)
        CGGEV3 computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices (blocked algorithm)

Purpose:
   CGGEV3 computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, and optionally, the left and/or
   right generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right generalized eigenvector v(j) corresponding to the
   generalized eigenvalue lambda(j) of (A,B) satisfies

      A * v(j) = lambda(j) * B * v(j).

   The left generalized eigenvector u(j) corresponding to the
   generalized eigenvalues lambda(j) of (A,B) satisfies

     u(j)**H * A = lambda(j) * u(j)**H * B
```

```
   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
e   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA, N)
   On entry, the matrix A in the pair (A,B).
   On exit, A has been overwritten.

 LDA
   LDA is INTEGER
   The leading dimension of A.  LDA >= max(1,N).

 B
   B is COMPLEX array, dimension (LDB, N)
   On entry, the matrix B in the pair (A,B).
   On exit, B has been overwritten.

 LDB
   LDB is INTEGER
   The leading dimension of B.  LDB >= max(1,N).

 ALPHA
   ALPHA is COMPLEX array, dimension (N)

 BETA
   BETA is COMPLEX array, dimension (N)
   On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the
   generalized eigenvalues.

   Note: the quotients ALPHA(j)/BETA(j) may easily over- or
   underflow, and BETA(j) may even be zero.  Thus, the user
   should avoid naively computing the ratio alpha/beta.
   However, ALPHA will be always less than and usually
   comparable with norm(A) in magnitude, and BETA always less
```

```
  than and usually comparable with norm(B).

VL
  VL is COMPLEX array, dimension (LDVL,N)
  If JOBVL = 'V', the left generalized eigenvectors u(j) are
  stored one after another in the columns of VL, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX array, dimension (LDVR,N)
  If JOBVR = 'V', the right generalized eigenvectors v(j) are
  stored one after another in the columns of VR, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (8*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

```
=1,...,N:
      The QZ iteration failed.  No eigenvectors have been
      calculated, but ALPHA(j) and BETA(j) should be
      correct for j=INFO+1,...,N.
> N:  =N+1: other then QZ iteration failed in SHGEQZ,
      =N+2: error return from STGEVC.

       real, dimension( * ) RWORK, integer, dimension( * ) IWORK, logical,
       dimension( * ) BWORK, integer INFO)
        CGGEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   CGGEVX computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B) the generalized eigenvalues, and optionally, the left and/or
   right generalized eigenvectors.

   Optionally, it also computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for
   the eigenvalues (RCONDE), and reciprocal condition numbers for the
```

```
   right eigenvectors (RCONDV).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies
      A * v(j) = lambda(j) * B * v(j) .
   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies
      u(j)**H * A  = lambda(j) * u(j)**H * B.
   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 BALANC
   BALANC is CHARACTER*1
   Specifies the balance option to be performed:
   = 'N':  do not diagonally scale or permute;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.
   Computed reciprocal condition numbers will be for the
   matrices after permuting and/or balancing. Permuting does
   not change condition numbers (in exact arithmetic), but balancing does.

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': none are computed;
   = 'E': computed for eigenvalues only;
   = 'V': computed for eigenvectors only;
   = 'B': computed for eigenvalues and eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA, N)
  On entry, the matrix A in the pair (A,B).
  On exit, A has been overwritten. If JOBVL='V' or JOBVR='V'
  or both, then A contains the first part of the complex Schur
  form of the "balanced" versions of the input A and B.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten. If JOBVL='V' or JOBVR='V'
  or both, then B contains the second part of the complex
  Schur form of the "balanced" versions of the input A and B.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHA
  ALPHA is COMPLEX array, dimension (N)

BETA
  BETA is COMPLEX array, dimension (N)
  On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized
  eigenvalues.

  Note: the quotient ALPHA(j)/BETA(j) ) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio ALPHA/BETA.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VL
  VL is COMPLEX array, dimension (LDVL,N)
  If JOBVL = 'V', the left generalized eigenvectors u(j) are
  stored one after another in the columns of VL, in the same
  order as their eigenvalues.
  Each eigenvector will be scaled so the largest component
  will have abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
```

```
  if JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX array, dimension (LDVR,N)
  If JOBVR = 'V', the right generalized eigenvectors v(j) are
  stored one after another in the columns of VR, in the same
  order as their eigenvalues.
  Each eigenvector will be scaled so the largest component
  will have abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If PL(j) is the index of the
  row interchanged with row j, and DL(j) is the scaling
  factor applied to row j, then
     LSCALE(j) = PL(j)  for j = 1,...,ILO-1
               = DL(j)  for j = ILO,...,IHI
               = PL(j)  for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

RSCALE
  RSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If PR(j) is the index of the
  column interchanged with column j, and DR(j) is the scaling
  factor applied to column j, then
     RSCALE(j) = PR(j)  for j = 1,...,ILO-1
               = DR(j)  for j = ILO,...,IHI
               = PR(j)  for j = IHI+1,...,N
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.
```

```
ABNRM
  ABNRM is REAL
  The one-norm of the balanced matrix A.

BBNRM
  BBNRM is REAL
  The one-norm of the balanced matrix B.

RCONDE
  RCONDE is REAL array, dimension (N)
  If SENSE = 'E' or 'B', the reciprocal condition numbers of
  the eigenvalues, stored in consecutive elements of the array.
  If SENSE = 'N' or 'V', RCONDE is not referenced.

RCONDV
  RCONDV is REAL array, dimension (N)
  If SENSE = 'V' or 'B', the estimated reciprocal condition
  numbers of the eigenvectors, stored in consecutive elements
  of the array. If the eigenvalues cannot be reordered to
  compute RCONDV(j), RCONDV(j) is set to 0; this can only occur
  when the true value would be very small anyway.
  If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= max(1,2*N).
  If SENSE = 'E', LWORK >= max(1,4*N).
  If SENSE = 'V' or 'B', LWORK >= max(1,2*N*N+2*N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (lrwork)
  lrwork must be at least max(1,6*N) if BALANC = 'S' or 'B',
  and at least max(1,2*N) otherwise.
  Real workspace.

IWORK
  IWORK is INTEGER array, dimension (N+2)
  If SENSE = 'E', IWORK is not referenced.

BWORK
  BWORK is LOGICAL array, dimension (N)
```

```
  If SENSE = 'N', BWORK is not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  No eigenvectors have been
        calculated, but ALPHA(j) and BETA(j) should be correct
        for j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in CHGEQZ.
        =N+2: error return from CTGEVC.

  Balancing a matrix pair (A,B) includes, first, permuting rows and
  columns to isolate eigenvalues, second, applying diagonal similarity
  transformation to the rows and columns to make the rows and columns
  as close in norm as possible. The computed reciprocal condition
  numbers correspond to the balanced matrix. Permuting rows and columns
  will not change the condition numbers (in exact arithmetic) but
  diagonal scaling will.  For further explanation of balancing, see
  section 4.11.1.2 of LAPACK Users' Guide.

  An approximate error bound on the chordal distance between the i-th
  computed generalized eigenvalue w and the corresponding exact
  eigenvalue lambda is

     chord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)

  An approximate error bound for the angle between the i-th computed
  eigenvector VL(i) or VR(i) is given by

     EPS * norm(ABNRM, BBNRM) / DIF(i).

  For further explanation of the reciprocal condition numbers RCONDE
  and RCONDV, see section 4.11 of LAPACK User's Guide.

SYNOPSIS
   Functions/Subroutines
       subroutine zgees (JOBVS, SORT, SELECT, N, A, LDA, SDIM, W, VS, LDVS,
           WORK, LWORK, RWORK, BWORK, INFO)
            ZGEES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine zgees (character JOBVS, character SORT, external SELECT, integer
       N, complex*16, dimension( lda, * ) A, integer LDA, integer SDIM,
       complex*16, dimension( * ) W, complex*16, dimension( ldvs, * ) VS,
       integer LDVS, complex*16, dimension( * ) WORK, integer LWORK, double
       precision, dimension( * ) RWORK, logical, dimension( * ) BWORK, integer
       INFO)
        ZGEES computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   ZGEES computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues, the Schur form T, and, optionally, the matrix of Schur
   vectors Z.  This gives the Schur factorization A = Z*T*(Z**H).

   Optionally, it also orders the eigenvalues on the diagonal of the
   Schur form so that selected eigenvalues are at the top left.
   The leading columns of Z then form an orthonormal basis for the
   invariant subspace corresponding to the selected eigenvalues.

   A complex matrix is in Schur form if it is upper triangular.

Parameters:

 JOBVS
   JOBVS is CHARACTER*1
   = 'N': Schur vectors are not computed;
   = 'V': Schur vectors are computed.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the Schur form.
   = 'N': Eigenvalues are not ordered:
   = 'S': Eigenvalues are ordered (see SELECT).

 SELECT
   SELECT is a LOGICAL FUNCTION of one COMPLEX*16 argument
```

```
  SELECT must be declared EXTERNAL in the calling subroutine.
  If SORT = 'S', SELECT is used to select eigenvalues to order
  to the top left of the Schur form.
  IF SORT = 'N', SELECT is not referenced.
  The eigenvalue W(j) is selected if SELECT(W(j)) is true.

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten by its Schur form T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

W
  W is COMPLEX*16 array, dimension (N)
  W contains the computed eigenvalues, in the same order that
  they appear on the diagonal of the output Schur form T.

VS
  VS is COMPLEX*16 array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1; if
  JOBVS = 'V', LDVS >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
```

```
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0: if INFO = i, and i is
   <= N:  the QR algorithm failed to compute all the
          eigenvalues; elements 1:ILO-1 and i+1:N of W
          contain those eigenvalues which have converged;
          if JOBVS = 'V', VS contains the matrix which
          reduces A to its partially converged Schur form.
   = N+1: the eigenvalues could not be reordered because
          some eigenvalues were too close to separate (the
          problem is very ill-conditioned);
   = N+2: after reordering, roundoff changed values of
          some complex eigenvalues so that leading
          eigenvalues in the Schur form no longer satisfy
          SELECT = .TRUE..  This could also be caused by
          underflow due to scaling.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgeesx (JOBVS, SORT, SELECT, SENSE, N, A, LDA, SDIM, W, VS,
           LDVS, RCONDE, RCONDV, WORK, LWORK, RWORK, BWORK, INFO)
            ZGEESX computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine zgeesx (character JOBVS, character SORT, external SELECT,
       character SENSE, integer N, complex*16, dimension( lda, * ) A, integer
       LDA, integer SDIM, complex*16, dimension( * ) W, complex*16, dimension(
       ldvs, * ) VS, integer LDVS, double precision RCONDE, double precision
       RCONDV, complex*16, dimension( * ) WORK, integer LWORK, double
       precision, dimension( * ) RWORK, logical, dimension( * ) BWORK, integer
       INFO)
        ZGEESX computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices

Purpose:
   ZGEESX computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues, the Schur form T, and, optionally, the matrix of Schur
   vectors Z.  This gives the Schur factorization A = Z*T*(Z**H).

   Optionally, it also orders the eigenvalues on the diagonal of the
   Schur form so that selected eigenvalues are at the top left;
   computes a reciprocal condition number for the average of the
   selected eigenvalues (RCONDE); and computes a reciprocal condition
   number for the right invariant subspace corresponding to the
   selected eigenvalues (RCONDV).  The leading columns of Z form an
   orthonormal basis for this invariant subspace.

   For further explanation of the reciprocal condition numbers RCONDE
   and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where
   these quantities are called s and sep respectively).

   A complex matrix is in Schur form if it is upper triangular.
```

```
Parameters:

 JOBVS
   JOBVS is CHARACTER*1
   = 'N': Schur vectors are not computed;
   = 'V': Schur vectors are computed.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the Schur form.
   = 'N': Eigenvalues are not ordered;
   = 'S': Eigenvalues are ordered (see SELECT).

 SELECT
   SELECT is procedure) LOGICAL FUNCTION of one COMPLEX*16 argument
   SELECT must be declared EXTERNAL in the calling subroutine.
   If SORT = 'S', SELECT is used to select eigenvalues to order
   to the top left of the Schur form.
   If SORT = 'N', SELECT is not referenced.
   An eigenvalue W(j) is selected if SELECT(W(j)) is true.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': None are computed;
   = 'E': Computed for average of selected eigenvalues only;
   = 'V': Computed for selected right invariant subspace only;
   = 'B': Computed for both.
   If SENSE = 'E', 'V' or 'B', SORT must equal 'S'.

 N
   N is INTEGER
   The order of the matrix A. N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA, N)
   On entry, the N-by-N matrix A.
   On exit, A is overwritten by its Schur form T.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 SDIM
   SDIM is INTEGER
   If SORT = 'N', SDIM = 0.
   If SORT = 'S', SDIM = number of eigenvalues for which SELECT is true.

 W
```

```
  W is COMPLEX*16 array, dimension (N)
  W contains the computed eigenvalues, in the same order
  that they appear on the diagonal of the output Schur form T.

VS
  VS is COMPLEX*16 array, dimension (LDVS,N)
  If JOBVS = 'V', VS contains the unitary matrix Z of Schur vectors.
  If JOBVS = 'N', VS is not referenced.

LDVS
  LDVS is INTEGER
  The leading dimension of the array VS.  LDVS >= 1, and if
  JOBVS = 'V', LDVS >= N.

RCONDE
  RCONDE is DOUBLE PRECISION
  If SENSE = 'E' or 'B', RCONDE contains the reciprocal
  condition number for the average of the selected eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is DOUBLE PRECISION
  If SENSE = 'V' or 'B', RCONDV contains the reciprocal
  condition number for the selected right invariant subspace.
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  Also, if SENSE = 'E' or 'V' or 'B', LWORK >= 2*SDIM*(N-SDIM),
  where SDIM is the number of selected eigenvalues computed by
  this routine.  Note that 2*SDIM*(N-SDIM) <= N*N/2. Note also
  that an error is only returned if LWORK < max(1,2*N), but if
  SENSE = 'E' or 'V' or 'B' this may not be large enough.
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates upper bound on the optimal size of the
  array WORK, returns this value as the first entry of the WORK
  array, and no error message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

BWORK
  BWORK is LOGICAL array, dimension (N)
```

```
  Not referenced if SORT = 'N'.

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.
  > 0: if INFO = i, and i is
    <= N: the QR algorithm failed to compute all the
          eigenvalues; elements 1:ILO-1 and i+1:N of W
          contain those eigenvalues which have converged; if
          JOBVS = 'V', VS contains the transformation which
          reduces A to its partially converged Schur form.
   = N+1: the eigenvalues could not be reordered because some
          eigenvalues were too close to separate (the problem
          is very ill-conditioned);
   = N+2: after reordering, roundoff changed values of some
          complex eigenvalues so that leading eigenvalues in
          the Schur form no longer satisfy SELECT=.TRUE.  This
          could also be caused by underflow due to scaling.

SYNOPSIS
   Functions/Subroutines
       subroutine zgeev (JOBVL, JOBVR, N, A, LDA, W, VL, LDVL, VR, LDVR, WORK,
           LWORK, RWORK, INFO)
            ZGEEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine zgeev (character JOBVL, character JOBVR, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( * ) W,
```

```
      complex*16, dimension( ldvl, * ) VL, integer LDVL, complex*16,
      dimension( ldvr, * ) VR, integer LDVR, complex*16, dimension( * ) WORK,
      integer LWORK, double precision, dimension( * ) RWORK, integer INFO)
       ZGEEV computes the eigenvalues and, optionally, the left and/or right
      eigenvectors for GE matrices

Purpose:
   ZGEEV computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   The right eigenvector v(j) of A satisfies
        A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
        u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N': left eigenvectors of A are not computed;
   = 'V': left eigenvectors of are computed.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N': right eigenvectors of A are not computed;
   = 'V': right eigenvectors of A are computed.

 N
   N is INTEGER
   The order of the matrix A. N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A.
   On exit, A has been overwritten.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 W
   W is COMPLEX*16 array, dimension (N)
   W contains the computed eigenvalues.

 VL
```

```
  VL is COMPLEX*16 array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  u(j) = VL(:,j), the j-th column of VL.

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX*16 array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  v(j) = VR(:,j), the j-th column of VR.

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1; if
  JOBVR = 'V', LDVR >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, the QR algorithm failed to compute all the
        eigenvalues, and no eigenvectors have been computed;
        elements and i+1:N of W contain eigenvalues which have converged.

SYNOPSIS
   Functions/Subroutines
       subroutine zgeevx (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, W, VL, LDVL,
           VR, LDVR, ILO, IHI, SCALE, ABNRM, RCONDE, RCONDV, WORK, LWORK,
           RWORK, INFO)
            ZGEEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine zgeevx (character BALANC, character JOBVL, character JOBVR,
       character SENSE, integer N, complex*16, dimension( lda, * ) A, integer
       LDA, complex*16, dimension( * ) W, complex*16, dimension( ldvl, * ) VL,
```

```
      integer LDVL, complex*16, dimension( ldvr, * ) VR, integer LDVR,
      integer ILO, integer IHI, double precision, dimension( * ) SCALE,
      double precision ABNRM, double precision, dimension( * ) RCONDE, double
      precision, dimension( * ) RCONDV, complex*16, dimension( * ) WORK,
      integer LWORK, double precision, dimension( * ) RWORK, integer INFO)
       ZGEEVX computes the eigenvalues and, optionally, the left and/or right
      eigenvectors for GE matrices

Purpose:
   ZGEEVX computes for an N-by-N complex nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvectors.

   Optionally also, it computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues
   (RCONDE), and reciprocal condition numbers for the right
   eigenvectors (RCONDV).

   The right eigenvector v(j) of A satisfies
        A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
        u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate transpose of u(j).

   The computed eigenvectors are normalized to have Euclidean norm
   equal to 1 and largest component real.

   Balancing a matrix means permuting the rows and columns to make it
   more nearly upper triangular, and applying a diagonal similarity
   transformation D * A * D**(-1), where D is a diagonal matrix, to
   make its rows and columns closer in norm and the condition numbers
   of its eigenvalues and eigenvectors smaller.  The computed
   reciprocal condition numbers correspond to the balanced matrix.
   Permuting rows and columns will not change the condition numbers
   (in exact arithmetic) but diagonal scaling will.  For further
   explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

Parameters:

 BALANC
   BALANC is CHARACTER*1
   Indicates how the input matrix should be diagonally scaled
   and/or permuted to improve the conditioning of its
   eigenvalues.
   = 'N': Do not diagonally scale or permute;
   = 'P': Perform permutations to make the matrix more nearly
          upper triangular. Do not diagonally scale;
   = 'S': Diagonally scale the matrix, ie. replace A by
          D*A*D**(-1), where D is a diagonal matrix chosen
```

```
          to make the rows and columns of A more equal in
          norm. Do not permute;
  = 'B': Both diagonally scale and permute A.

  Computed reciprocal condition numbers will be for the matrix
  after balancing and/or permuting. Permuting does not change
  condition numbers (in exact arithmetic), but balancing does.

JOBVL
  JOBVL is CHARACTER*1
  = 'N': left eigenvectors of A are not computed;
  = 'V': left eigenvectors of A are computed.
  If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR
  JOBVR is CHARACTER*1
  = 'N': right eigenvectors of A are not computed;
  = 'V': right eigenvectors of A are computed.
  If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N': None are computed;
  = 'E': Computed for eigenvalues only;
  = 'V': Computed for right eigenvectors only;
  = 'B': Computed for eigenvalues and right eigenvectors.

  If SENSE = 'E' or 'B', both left and right eigenvectors
  must also be computed (JOBVL = 'V' and JOBVR = 'V').

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.
  On exit, A has been overwritten.  If JOBVL = 'V' or
  JOBVR = 'V', A contains the Schur form of the balanced
  version of the matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

W
  W is COMPLEX*16 array, dimension (N)
  W contains the computed eigenvalues.
```

```
VL
  VL is COMPLEX*16 array, dimension (LDVL,N)
  If JOBVL = 'V', the left eigenvectors u(j) are stored one
  after another in the columns of VL, in the same order
  as their eigenvalues.
  If JOBVL = 'N', VL is not referenced.
  u(j) = VL(:,j), the j-th column of VL.

LDVL
  LDVL is INTEGER
  The leading dimension of the array VL.  LDVL >= 1; if
  JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX*16 array, dimension (LDVR,N)
  If JOBVR = 'V', the right eigenvectors v(j) are stored one
  after another in the columns of VR, in the same order
  as their eigenvalues.
  If JOBVR = 'N', VR is not referenced.
  v(j) = VR(:,j), the j-th column of VR.

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1; if
  JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values determined when A was
  balanced.  The balanced A(i,j) = 0 if I > J and
  J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE
  SCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  when balancing A.  If P(j) is the index of the row and column
  interchanged with row and column j, and D(j) is the scaling
  factor applied to row and column j, then
  SCALE(J) = P(J),    for J = 1,...,ILO-1
           = D(J),    for J = ILO,...,IHI
           = P(J)     for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

ABNRM
  ABNRM is DOUBLE PRECISION
  The one-norm of the balanced matrix (the maximum
```

```
  of the sum of absolute values of elements of any column).

RCONDE
  RCONDE is DOUBLE PRECISION array, dimension (N)
  RCONDE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONDV
  RCONDV is DOUBLE PRECISION array, dimension (N)
  RCONDV(j) is the reciprocal condition number of the j-th
  right eigenvector.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  If SENSE = 'N' or 'E',
  LWORK >= max(1,2*N), and if SENSE = 'V' or 'B',
  LWORK >= N*N+2*N.
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, the QR algorithm failed to compute all the
        eigenvalues, and no eigenvectors or condition numbers
        have been computed; elements 1:ILO-1 and i+1:N of W
        contain eigenvalues which have converged.

SYNOPSIS
   Functions/Subroutines
       subroutine zgges (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK,
           BWORK, INFO)
            ZGGES computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices

Function/Subroutine Documentation
   subroutine zgges (character JOBVSL, character JOBVSR, character SORT,
```

```
      external SELCTG, integer N, complex*16, dimension( lda, * ) A, integer
      LDA, complex*16, dimension( ldb, * ) B, integer LDB, integer SDIM,
      complex*16, dimension( * ) ALPHA, complex*16, dimension( * ) BETA,
      complex*16, dimension( ldvsl, * ) VSL, integer LDVSL, complex*16,
      dimension( ldvsr, * ) VSR, integer LDVSR, complex*16, dimension( * )
      WORK, integer LWORK, double precision, dimension( * ) RWORK, logical,
      dimension( * ) BWORK, integer INFO)
       ZGGES computes the eigenvalues, the Schur form, and, optionally, the
      matrix of Schur vectors for GE matrices

Purpose:
   ZGGES computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, the generalized complex Schur
   form (S, T), and optionally left and/or right Schur vectors (VSL
   and VSR). This gives the generalized Schur factorization

   (A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )

   where (VSR)**H is the conjugate-transpose of VSR.

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   triangular matrix S and the upper triangular matrix T. The leading
   columns of VSL and VSR then form an unitary basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
   ZGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0, and even for both being zero.

   A pair of matrices (S,T) is in generalized complex Schur form if S
   and T are upper triangular and, in addition, the diagonal elements
   of T are non-negative real numbers.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.
```

```
SORT
  SORT is CHARACTER*1
  Specifies whether or not to order the eigenvalues on the
  diagonal of the generalized Schur form.
  = 'N':  Eigenvalues are not ordered;
  = 'S':  Eigenvalues are ordered (see SELCTG).

SELCTG
  SELCTG is a LOGICAL FUNCTION of two COMPLEX*16 arguments
  SELCTG must be declared EXTERNAL in the calling subroutine.
  If SORT = 'N', SELCTG is not referenced.
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  An eigenvalue ALPHA(j)/BETA(j) is selected if
  SELCTG(ALPHA(j),BETA(j)) is true.

  Note that a selected complex eigenvalue may no longer satisfy
  SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned), in this
  case INFO is set to N+2 (See INFO below).

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.
```

```
ALPHA
  ALPHA is COMPLEX*16 array, dimension (N)

BETA
  BETA is COMPLEX*16 array, dimension (N)
  On exit,  ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.  ALPHA(j), j=1,...,N  and  BETA(j),
  j=1,...,N  are the diagonals of the complex Schur form (A,B)
  output by ZGGES. The  BETA(j) will be non-negative real.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VSL
  VSL is COMPLEX*16 array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >= 1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is COMPLEX*16 array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.
```

```
 RWORK
   RWORK is DOUBLE PRECISION array, dimension (8*N)

 BWORK
   BWORK is LOGICAL array, dimension (N)
   Not referenced if SORT = 'N'.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   =1,...,N:
         The QZ iteration failed.  (A,B) are not in Schur
         form, but ALPHA(j) and BETA(j) should be correct for
         j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in ZHGEQZ
         =N+2: after reordering, roundoff changed values of
               some complex eigenvalues so that leading
               eigenvalues in the Generalized Schur form no
               longer satisfy SELCTG=.TRUE.  This could also
               be caused due to scaling.
         =N+3: reordering failed in ZTGSEN.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgges3 (JOBVSL, JOBVSR, SORT, SELCTG, N, A, LDA, B, LDB,
           SDIM, ALPHA, BETA, VSL, LDVSL, VSR, LDVSR, WORK, LWORK, RWORK,
           BWORK, INFO)
            ZGGES3 computes the eigenvalues, the Schur form, and, optionally,
           the matrix of Schur vectors for GE matrices (blocked algorithm)

Function/Subroutine Documentation
   subroutine zgges3 (character JOBVSL, character JOBVSR, character SORT,
       external SELCTG, integer N, complex*16, dimension( lda, * ) A, integer
       LDA, complex*16, dimension( ldb, * ) B, integer LDB, integer SDIM,
       complex*16, dimension( * ) ALPHA, complex*16, dimension( * ) BETA,
       complex*16, dimension( ldvsl, * ) VSL, integer LDVSL, complex*16,
       dimension( ldvsr, * ) VSR, integer LDVSR, complex*16, dimension( * )
       WORK, integer LWORK, double precision, dimension( * ) RWORK, logical,
       dimension( * ) BWORK, integer INFO)
        ZGGES3 computes the eigenvalues, the Schur form, and, optionally, the
       matrix of Schur vectors for GE matrices (blocked algorithm)

Purpose:
   ZGGES3 computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, the generalized complex Schur
   form (S, T), and optionally left and/or right Schur vectors (VSL
   and VSR). This gives the generalized Schur factorization

   (A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )

   where (VSR)**H is the conjugate-transpose of VSR.

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   triangular matrix S and the upper triangular matrix T. The leading
   columns of VSL and VSR then form an unitary basis for the
   corresponding left and right eigenspaces (deflating subspaces).

   (If only the generalized eigenvalues are needed, use the driver
```

```
   ZGGEV instead, which is faster.)

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0, and even for both being zero.

   A pair of matrices (S,T) is in generalized complex Schur form if S
   and T are upper triangular and, in addition, the diagonal elements
   of T are non-negative real numbers.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
   diagonal of the generalized Schur form.
   = 'N':  Eigenvalues are not ordered;
   = 'S':  Eigenvalues are ordered (see SELCTG).

 SELCTG
   SELCTG is a LOGICAL FUNCTION of two COMPLEX*16 arguments
   SELCTG must be declared EXTERNAL in the calling subroutine.
   If SORT = 'N', SELCTG is not referenced.
   If SORT = 'S', SELCTG is used to select eigenvalues to sort
   to the top left of the Schur form.
   An eigenvalue ALPHA(j)/BETA(j) is selected if
   SELCTG(ALPHA(j),BETA(j)) is true.

   Note that a selected complex eigenvalue may no longer satisfy
   SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since
   ordering may change the value of complex eigenvalues
   (especially if the eigenvalue is ill-conditioned), in this
   case INFO is set to N+2 (See INFO below).

 N
   N is INTEGER
   The order of the matrices A, B, VSL, and VSR.  N >= 0.

 A
```

```
  A is COMPLEX*16 array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.

ALPHA
  ALPHA is COMPLEX*16 array, dimension (N)

BETA
  BETA is COMPLEX*16 array, dimension (N)
  On exit,  ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.  ALPHA(j), j=1,...,N  and  BETA(j),
  j=1,...,N  are the diagonals of the complex Schur form (A,B)
  output by ZGGES3. The  BETA(j) will be non-negative real.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VSL
  VSL is COMPLEX*16 array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >= 1, and
  if JOBVSL = 'V', LDVSL >= N.
```

```
VSR
  VSR is COMPLEX*16 array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (8*N)

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  =1,...,N:
        The QZ iteration failed.  (A,B) are not in Schur
        form, but ALPHA(j) and BETA(j) should be correct for
        j=INFO+1,...,N.
  > N:  =N+1: other than QZ iteration failed in ZHGEQZ
        =N+2: after reordering, roundoff changed values of
              some complex eigenvalues so that leading
              eigenvalues in the Generalized Schur form no
              longer satisfy SELCTG=.TRUE.  This could also
              be caused due to scaling.
        =N+3: reordering failed in ZTGSEN.
```

      precision, dimension( * ) RWORK, integer, dimension( * ) IWORK, integer
      LIWORK, logical, dimension( * ) BWORK, integer INFO)
       ZGGESX computes the eigenvalues, the Schur form, and, optionally, the
      matrix of Schur vectors for GE matrices

Purpose:
   ZGGESX computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, the complex Schur form (S,T),
   and, optionally, the left and/or right matrices of Schur vectors (VSL
   and VSR).  This gives the generalized Schur factorization

   (A,B) = ( (VSL) S (VSR)**H, (VSL) T (VSR)**H )

   where (VSR)**H is the conjugate-transpose of VSR.

   Optionally, it also orders the eigenvalues so that a selected cluster
   of eigenvalues appears in the leading diagonal blocks of the upper
   triangular matrix S and the upper triangular matrix T; computes
   a reciprocal condition number for the average of the selected
   eigenvalues (RCONDE); and computes a reciprocal condition number for
   the right and left deflating subspaces corresponding to the selected
   eigenvalues (RCONDV). The leading columns of VSL and VSR then form
   an orthonormal basis for the corresponding left and right eigenspaces
   (deflating subspaces).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar w
   or a ratio alpha/beta = w, such that  A - w*B is singular.  It is
   usually represented as the pair (alpha,beta), as there is a
   reasonable interpretation for beta=0 or for both being zero.

   A pair of matrices (S,T) is in generalized complex Schur form if T is
   upper triangular with non-negative diagonal and S is upper
   triangular.

Parameters:

 JOBVSL
   JOBVSL is CHARACTER*1
   = 'N':  do not compute the left Schur vectors;
   = 'V':  compute the left Schur vectors.

 JOBVSR
   JOBVSR is CHARACTER*1
   = 'N':  do not compute the right Schur vectors;
   = 'V':  compute the right Schur vectors.

 SORT
   SORT is CHARACTER*1
   Specifies whether or not to order the eigenvalues on the
```

```
  diagonal of the generalized Schur form.
  = 'N':  Eigenvalues are not ordered;
  = 'S':  Eigenvalues are ordered (see SELCTG).

SELCTG
  SELCTG is procedure) LOGICAL FUNCTION of two COMPLEX*16 arguments
  SELCTG must be declared EXTERNAL in the calling subroutine.
  If SORT = 'N', SELCTG is not referenced.
  If SORT = 'S', SELCTG is used to select eigenvalues to sort
  to the top left of the Schur form.
  Note that a selected complex eigenvalue may no longer satisfy
  SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since
  ordering may change the value of complex eigenvalues
  (especially if the eigenvalue is ill-conditioned), in this
  case INFO is set to N+3 see INFO below).

SENSE
  SENSE is CHARACTER*1
  Determines which reciprocal condition numbers are computed.
  = 'N' : None are computed;
  = 'E' : Computed for average of selected eigenvalues only;
  = 'V' : Computed for selected deflating subspaces only;
  = 'B' : Computed for both.
  If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N
  N is INTEGER
  The order of the matrices A, B, VSL, and VSR.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA, N)
  On entry, the first of the pair of matrices.
  On exit, A has been overwritten by its generalized Schur form S.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB, N)
  On entry, the second of the pair of matrices.
  On exit, B has been overwritten by its generalized Schur form T.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

SDIM
  SDIM is INTEGER
  If SORT = 'N', SDIM = 0.
```

```
  If SORT = 'S', SDIM = number of eigenvalues (after sorting)
  for which SELCTG is true.

ALPHA
  ALPHA is COMPLEX*16 array, dimension (N)

BETA
  BETA is COMPLEX*16 array, dimension (N)
  On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.  ALPHA(j) and BETA(j),j=1,...,N  are
  the diagonals of the complex Schur form (S,T).  BETA(j) will
  be non-negative real.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VSL
  VSL is COMPLEX*16 array, dimension (LDVSL,N)
  If JOBVSL = 'V', VSL will contain the left Schur vectors.
  Not referenced if JOBVSL = 'N'.

LDVSL
  LDVSL is INTEGER
  The leading dimension of the matrix VSL. LDVSL >=1, and
  if JOBVSL = 'V', LDVSL >= N.

VSR
  VSR is COMPLEX*16 array, dimension (LDVSR,N)
  If JOBVSR = 'V', VSR will contain the right Schur vectors.
  Not referenced if JOBVSR = 'N'.

LDVSR
  LDVSR is INTEGER
  The leading dimension of the matrix VSR. LDVSR >= 1, and
  if JOBVSR = 'V', LDVSR >= N.

RCONDE
  RCONDE is DOUBLE PRECISION array, dimension ( 2 )
  If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the
  reciprocal condition numbers for the average of the selected eigenvalues.
  Not referenced if SENSE = 'N' or 'V'.

RCONDV
  RCONDV is DOUBLE PRECISION array, dimension ( 2 )
  If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the
  reciprocal condition number for the selected deflating subspaces.
```

```
  Not referenced if SENSE = 'N' or 'E'.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N = 0, LWORK >= 1, else if SENSE = 'E', 'V', or 'B',
  LWORK >= MAX(1,2*N,2*SDIM*(N-SDIM)), else
  LWORK >= MAX(1,2*N).  Note that 2*SDIM*(N-SDIM) <= N*N/2.
  Note also that an error is only returned if
  LWORK < MAX(1,2*N), but if SENSE = 'E' or 'V' or 'B' this may
  not be large enough.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the bound on the optimal size of the WORK
  array and the minimum size of the IWORK array, returns these
  values as the first entries of the WORK and IWORK arrays, and
  no error message related to LWORK or LIWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension ( 8*N )
  Real workspace.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the minimum LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  If SENSE = 'N' or N = 0, LIWORK >= 1, otherwise
  LIWORK >= N+2.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the bound on the optimal size of the
  WORK array and the minimum size of the IWORK array, returns
  these values as the first entries of the WORK and IWORK
  arrays, and no error message related to LWORK or LIWORK is
  issued by XERBLA.

BWORK
  BWORK is LOGICAL array, dimension (N)
  Not referenced if SORT = 'N'.

INFO
  INFO is INTEGER
  = 0:  successful exit
```

```
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
        The QZ iteration failed.  (A,B) are not in Schur
        form, but ALPHA(j) and BETA(j) should be correct for
        j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in ZHGEQZ
         =N+2: after reordering, roundoff changed values of
               some complex eigenvalues so that leading
               eigenvalues in the Generalized Schur form no
               longer satisfy SELCTG=.TRUE.  This could also
               be caused due to scaling.
         =N+3: reordering failed in ZTGSEN.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zggev (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL,
           LDVL, VR, LDVR, WORK, LWORK, RWORK, INFO)
            ZGGEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine zggev (character JOBVL, character JOBVR, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, complex*16, dimension( * ) ALPHA, complex*16, dimension( *
       ) BETA, complex*16, dimension( ldvl, * ) VL, integer LDVL, complex*16,
       dimension( ldvr, * ) VR, integer LDVR, complex*16, dimension( * ) WORK,
       integer LWORK, double precision, dimension( * ) RWORK, integer INFO)
        ZGGEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   ZGGEV computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, and optionally, the left and/or
   right generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right generalized eigenvector v(j) corresponding to the
   generalized eigenvalue lambda(j) of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j).

   The left generalized eigenvector u(j) corresponding to the
   generalized eigenvalues lambda(j) of (A,B) satisfies

   u(j)**H * A = lambda(j) * u(j)**H * B
```

```
   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA, N)
   On entry, the matrix A in the pair (A,B).
   On exit, A has been overwritten.

 LDA
   LDA is INTEGER
   The leading dimension of A.  LDA >= max(1,N).

 B
   B is COMPLEX*16 array, dimension (LDB, N)
   On entry, the matrix B in the pair (A,B).
   On exit, B has been overwritten.

 LDB
   LDB is INTEGER
   The leading dimension of B.  LDB >= max(1,N).

 ALPHA
   ALPHA is COMPLEX*16 array, dimension (N)

 BETA
   BETA is COMPLEX*16 array, dimension (N)
   On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the
   generalized eigenvalues.

   Note: the quotients ALPHA(j)/BETA(j) may easily over- or
   underflow, and BETA(j) may even be zero.  Thus, the user
   should avoid naively computing the ratio alpha/beta.
   However, ALPHA will be always less than and usually
   comparable with norm(A) in magnitude, and BETA always less
```

```
  than and usually comparable with norm(B).

VL
  VL is COMPLEX*16 array, dimension (LDVL,N)
  If JOBVL = 'V', the left generalized eigenvectors u(j) are
  stored one after another in the columns of VL, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX*16 array, dimension (LDVR,N)
  If JOBVR = 'V', the right generalized eigenvectors v(j) are
  stored one after another in the columns of VR, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,2*N).
  For good performance, LWORK must generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (8*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
```

```
< 0:  if INFO = -i, the i-th argument had an illegal value.
=1,...,N:
      The QZ iteration failed.  No eigenvectors have been
      calculated, but ALPHA(j) and BETA(j) should be
      correct for j=INFO+1,...,N.
> N:  =N+1: other then QZ iteration failed in DHGEQZ,
      =N+2: error return from DTGEVC.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zggev3 (JOBVL, JOBVR, N, A, LDA, B, LDB, ALPHA, BETA, VL,
           LDVL, VR, LDVR, WORK, LWORK, RWORK, INFO)
            ZGGEV3 computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices (blocked algorithm)

Function/Subroutine Documentation
   subroutine zggev3 (character JOBVL, character JOBVR, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, complex*16, dimension( * ) ALPHA, complex*16, dimension( *
       ) BETA, complex*16, dimension( ldvl, * ) VL, integer LDVL, complex*16,
       dimension( ldvr, * ) VR, integer LDVR, complex*16, dimension( * ) WORK,
       integer LWORK, double precision, dimension( * ) RWORK, integer INFO)
        ZGGEV3 computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices (blocked algorithm)

Purpose:
   ZGGEV3 computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B), the generalized eigenvalues, and optionally, the left and/or
   right generalized eigenvectors.

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right generalized eigenvector v(j) corresponding to the
   generalized eigenvalue lambda(j) of (A,B) satisfies

   A * v(j) = lambda(j) * B * v(j).

   The left generalized eigenvector u(j) corresponding to the
   generalized eigenvalues lambda(j) of (A,B) satisfies

   u(j)**H * A = lambda(j) * u(j)**H * B

   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
```

```
  = 'N':  do not compute the right generalized eigenvectors;
  = 'V':  compute the right generalized eigenvectors.

N
  N is INTEGER
  The order of the matrices A, B, VL, and VR.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA, N)
  On entry, the matrix A in the pair (A,B).
  On exit, A has been overwritten.

LDA
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHA
  ALPHA is COMPLEX*16 array, dimension (N)

BETA
  BETA is COMPLEX*16 array, dimension (N)
  On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the
  generalized eigenvalues.

  Note: the quotients ALPHA(j)/BETA(j) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio alpha/beta.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VL
  VL is COMPLEX*16 array, dimension (LDVL,N)
  If JOBVL = 'V', the left generalized eigenvectors u(j) are
  stored one after another in the columns of VL, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
```

```
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX*16 array, dimension (LDVR,N)
  If JOBVR = 'V', the right generalized eigenvectors v(j) are
  stored one after another in the columns of VR, in the same
  order as their eigenvalues.
  Each eigenvector is scaled so the largest component has
  abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (8*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  =1,...,N:
        The QZ iteration failed.  No eigenvectors have been
        calculated, but ALPHA(j) and BETA(j) should be
        correct for j=INFO+1,...,N.
  > N:  =N+1: other then QZ iteration failed in DHGEQZ,
        =N+2: error return from DTGEVC.

SYNOPSIS
   Functions/Subroutines
       subroutine zggevx (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB,
           ALPHA, BETA, VL, LDVL, VR, LDVR, ILO, IHI, LSCALE, RSCALE, ABNRM,
           BBNRM, RCONDE, RCONDV, WORK, LWORK, RWORK, IWORK, BWORK, INFO)
            ZGGEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for GE matrices

Function/Subroutine Documentation
   subroutine zggevx (character BALANC, character JOBVL, character JOBVR,
       character SENSE, integer N, complex*16, dimension( lda, * ) A, integer
       LDA, complex*16, dimension( ldb, * ) B, integer LDB, complex*16,

       dimension( * ) WORK, integer LWORK, double precision, dimension( * )
       RWORK, integer, dimension( * ) IWORK, logical, dimension( * ) BWORK,
       integer INFO)
        ZGGEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for GE matrices

Purpose:
   ZGGEVX computes for a pair of N-by-N complex nonsymmetric matrices
   (A,B) the generalized eigenvalues, and optionally, the left and/or
   right generalized eigenvectors.

   Optionally, it also computes a balancing transformation to improve
   the conditioning of the eigenvalues and eigenvectors (ILO, IHI,
   LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for
   the eigenvalues (RCONDE), and reciprocal condition numbers for the
   right eigenvectors (RCONDV).

   A generalized eigenvalue for a pair of matrices (A,B) is a scalar
   lambda or a ratio alpha/beta = lambda, such that A - lambda*B is
   singular. It is usually represented as the pair (alpha,beta), as
   there is a reasonable interpretation for beta=0, and even for both
   being zero.

   The right eigenvector v(j) corresponding to the eigenvalue lambda(j)
```

```
   of (A,B) satisfies
   A * v(j) = lambda(j) * B * v(j) .
   The left eigenvector u(j) corresponding to the eigenvalue lambda(j)
   of (A,B) satisfies
   u(j)**H * A  = lambda(j) * u(j)**H * B.
   where u(j)**H is the conjugate-transpose of u(j).

Parameters:

 BALANC
   BALANC is CHARACTER*1
   Specifies the balance option to be performed:
   = 'N':  do not diagonally scale or permute;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.
   Computed reciprocal condition numbers will be for the
   matrices after permuting and/or balancing. Permuting does
   not change condition numbers (in exact arithmetic), but balancing does.

 JOBVL
   JOBVL is CHARACTER*1
   = 'N':  do not compute the left generalized eigenvectors;
   = 'V':  compute the left generalized eigenvectors.

 JOBVR
   JOBVR is CHARACTER*1
   = 'N':  do not compute the right generalized eigenvectors;
   = 'V':  compute the right generalized eigenvectors.

 SENSE
   SENSE is CHARACTER*1
   Determines which reciprocal condition numbers are computed.
   = 'N': none are computed;
   = 'E': computed for eigenvalues only;
   = 'V': computed for eigenvectors only;
   = 'B': computed for eigenvalues and eigenvectors.

 N
   N is INTEGER
   The order of the matrices A, B, VL, and VR.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA, N)
   On entry, the matrix A in the pair (A,B).
   On exit, A has been overwritten. If JOBVL='V' or JOBVR='V'
   or both, then A contains the first part of the complex Schur
   form of the "balanced" versions of the input A and B.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of A.  LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB, N)
  On entry, the matrix B in the pair (A,B).
  On exit, B has been overwritten. If JOBVL='V' or JOBVR='V'
  or both, then B contains the second part of the complex
  Schur form of the "balanced" versions of the input A and B.

LDB
  LDB is INTEGER
  The leading dimension of B.  LDB >= max(1,N).

ALPHA
  ALPHA is COMPLEX*16 array, dimension (N)

BETA
  BETA is COMPLEX*16 array, dimension (N)
  On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized
  eigenvalues.

  Note: the quotient ALPHA(j)/BETA(j) ) may easily over- or
  underflow, and BETA(j) may even be zero.  Thus, the user
  should avoid naively computing the ratio ALPHA/BETA.
  However, ALPHA will be always less than and usually
  comparable with norm(A) in magnitude, and BETA always less
  than and usually comparable with norm(B).

VL
  VL is COMPLEX*16 array, dimension (LDVL,N)
  If JOBVL = 'V', the left generalized eigenvectors u(j) are
  stored one after another in the columns of VL, in the same
  order as their eigenvalues.
  Each eigenvector will be scaled so the largest component
  will have abs(real part) + abs(imag. part) = 1.
  Not referenced if JOBVL = 'N'.

LDVL
  LDVL is INTEGER
  The leading dimension of the matrix VL. LDVL >= 1, and
  if JOBVL = 'V', LDVL >= N.

VR
  VR is COMPLEX*16 array, dimension (LDVR,N)
  If JOBVR = 'V', the right generalized eigenvectors v(j) are
  stored one after another in the columns of VR, in the same
  order as their eigenvalues.
  Each eigenvector will be scaled so the largest component
  will have abs(real part) + abs(imag. part) = 1.
```

```
  Not referenced if JOBVR = 'N'.

LDVR
  LDVR is INTEGER
  The leading dimension of the matrix VR. LDVR >= 1, and
  if JOBVR = 'V', LDVR >= N.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are integer values such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If PL(j) is the index of the
  row interchanged with row j, and DL(j) is the scaling
  factor applied to row j, then
  LSCALE(j) = PL(j)  for j = 1,...,ILO-1
            = DL(j)  for j = ILO,...,IHI
            = PL(j)  for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

RSCALE
  RSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If PR(j) is the index of the
  column interchanged with column j, and DR(j) is the scaling
  factor applied to column j, then
  RSCALE(j) = PR(j)  for j = 1,...,ILO-1
            = DR(j)  for j = ILO,...,IHI
            = PR(j)  for j = IHI+1,...,N
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

ABNRM
  ABNRM is DOUBLE PRECISION
  The one-norm of the balanced matrix A.

BBNRM
  BBNRM is DOUBLE PRECISION
  The one-norm of the balanced matrix B.

RCONDE
```

```
  RCONDE is DOUBLE PRECISION array, dimension (N)
  If SENSE = 'E' or 'B', the reciprocal condition numbers of
  the eigenvalues, stored in consecutive elements of the array.
  If SENSE = 'N' or 'V', RCONDE is not referenced.

RCONDV
  RCONDV is DOUBLE PRECISION array, dimension (N)
  If JOB = 'V' or 'B', the estimated reciprocal condition
  numbers of the eigenvectors, stored in consecutive elements
  of the array. If the eigenvalues cannot be reordered to
  compute RCONDV(j), RCONDV(j) is set to 0; this can only occur
  when the true value would be very small anyway.
  If SENSE = 'N' or 'E', RCONDV is not referenced.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= max(1,2*N).
  If SENSE = 'E', LWORK >= max(1,4*N).
  If SENSE = 'V' or 'B', LWORK >= max(1,2*N*N+2*N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (lrwork)
  lrwork must be at least max(1,6*N) if BALANC = 'S' or 'B',
  and at least max(1,2*N) otherwise.
  Real workspace.

IWORK
  IWORK is INTEGER array, dimension (N+2)
  If SENSE = 'E', IWORK is not referenced.

BWORK
  BWORK is LOGICAL array, dimension (N)
  If SENSE = 'N', BWORK is not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  = 1,...,N:
         The QZ iteration failed.  No eigenvectors have been
         calculated, but ALPHA(j) and BETA(j) should be correct
```

```
          for j=INFO+1,...,N.
   > N:  =N+1: other than QZ iteration failed in ZHGEQZ.
         =N+2: error return from ZTGEVC.

Further Details:
   Balancing a matrix pair (A,B) includes, first, permuting rows and
   columns to isolate eigenvalues, second, applying diagonal similarity
   transformation to the rows and columns to make the rows and columns
   as close in norm as possible. The computed reciprocal condition
   numbers correspond to the balanced matrix. Permuting rows and columns
   will not change the condition numbers (in exact arithmetic) but
   diagonal scaling will.  For further explanation of balancing, see
   section 4.11.1.2 of LAPACK Users' Guide.

   An approximate error bound on the chordal distance between the i-th
   computed generalized eigenvalue w and the corresponding exact
   eigenvalue lambda is

   chord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)

   An approximate error bound for the angle between the i-th computed
   eigenvector VL(i) or VR(i) is given by

   EPS * norm(ABNRM, BBNRM) / DIF(i).

   For further explanation of the reciprocal condition numbers RCONDE
   and RCONDV, see section 4.11 of LAPACK User's Guide.

       dimension( * ) IWORK, integer INFO)
       DGEJSV

Purpose:
   DGEJSV computes the singular value decomposition (SVD) of a real M-by-N
   matrix [A], where M >= N. The SVD of [A] is written as

         [A] = [U] * [SIGMA] * [V]^t,

   where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N
   diagonal elements, [U] is an M-by-N (or M-by-M) orthonormal matrix, and
   [V] is an N-by-N orthogonal matrix. The diagonal elements of [SIGMA] are
   the singular values of [A]. The columns of [U] and [V] are the left and
   the right singular vectors of [A], respectively. The matrices [U] and [V]
   are computed and stored in the arrays U and V, respectively. The diagonal
   of [SIGMA] is computed and stored in the array SVA.
   DGEJSV can sometimes compute tiny singular values and their singular
   vectors much more accurately than other SVD routines,
   see below under Further Details.*>

Parameters:

 JOBA
   JOBA is CHARACTER*1
   Specifies the level of accuracy:
   = 'C': This option works well (high relative accuracy) if A = B * D,
          with well-conditioned B and arbitrary diagonal matrix D.
          The accuracy cannot be spoiled by COLUMN scaling. The
          accuracy of the computed output depends on the condition of
          B, and the procedure aims at the best theoretical accuracy.
          The relative error max_{i=1:N}|d sigma_i| / sigma_i is
          bounded by f(M,N)*epsilon* cond(B), independent of D.
```

```
         The input matrix is preprocessed with the QRF with column
         pivoting. This initial preprocessing and preconditioning by
         a rank revealing QR factorization is common for all values of
         JOBA. Additional actions are specified as follows:
  = 'E': Computation as with 'C' with an additional estimate of the
         condition number of B. It provides a realistic error bound.
  = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings
         D1, D2, and well-conditioned matrix C, this option gives
         higher accuracy than the 'C' option. If the structure of the
         input matrix is not known, and relative accuracy is
         desirable, then this option is advisable. The input matrix A
         is preprocessed with QR factorization with FULL (row and
         column) pivoting.
  = 'G'  Computation as with 'F' with an additional estimate of the
         condition number of B, where A=D*B. If A has heavily weighted
         rows, then using this condition number gives too pessimistic
         error bound.
  = 'A': Small singular values are the noise and the matrix is treated
         as numerically rank defficient. The error in the computed
         singular values is bounded by f(m,n)*epsilon*||A||.
         The computed SVD A = U * S * V^t restores A up to
         f(m,n)*epsilon*||A||.
         This gives the procedure the licence to discard (set to zero)
         all singular values below N*epsilon*||A||.
  = 'R': Similar as in 'A'. Rank revealing property of the initial
         QR factorization is used do reveal (using triangular factor)
         a gap sigma_{r+1} < epsilon * sigma_r in which case the
         numerical RANK is declared to be r. The SVD is computed with
         absolute error bounds, but more accurately than with 'A'.

JOBU
  JOBU is CHARACTER*1
  Specifies whether to compute the columns of U:
  = 'U': N columns of U are returned in the array U.
  = 'F': full set of M left sing. vectors is returned in the array U.
  = 'W': U may be used as workspace of length M*N. See the description of U.
  = 'N': U is not computed.

JOBV
  JOBV is CHARACTER*1
  Specifies whether to compute the matrix V:
  = 'V': N columns of V are returned in the array V; Jacobi rotations
         are not explicitly accumulated.
  = 'J': N columns of V are returned in the array V, but they are
         computed as the product of Jacobi rotations. This option is
         allowed only if JOBU .NE. 'N', i.e. in computing the full SVD.
  = 'W': V may be used as workspace of length N*N. See the description of V.
  = 'N': V is not computed.

JOBR
```

```
  JOBR is CHARACTER*1
  Specifies the RANGE for the singular values. Issues the licence to
  set to zero small positive singular values if they are outside
  specified range. If A .NE. 0 is scaled so that the largest singular
  value of c*A is around DSQRT(BIG), BIG=SLAMCH('O'), then JOBR issues
  the licence to kill columns of A whose norm in c*A is less than
  DSQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN,
  where SFMIN=SLAMCH('S'), EPSLN=SLAMCH('E').
  = 'N': Do not kill small columns of c*A. This option assumes that
         BLAS and QR factorizations and triangular solvers are
         implemented to work in that range. If the condition of A
         is greater than BIG, use DGESVJ.
  = 'R': RESTRICTED range for sigma(c*A) is [DSQRT(SFMIN), DSQRT(BIG)]
         (roughly, as described above). This option is recommended.
                         ~~~~~~~~~~~~~~~~~~~~~~~~~~~
         For computing the singular values in the FULL range [SFMIN,BIG]
         use DGESVJ.

JOBT
  JOBT is CHARACTER*1
  If the matrix is square then the procedure may determine to use
  transposed A if A^t seems to be better with respect to convergence.
  If the matrix is not square, JOBT is ignored. This is subject to
  changes in the future.
  The decision is based on two values of entropy over the adjoint
  orbit of A^t * A. See the descriptions of WORK(6) and WORK(7).
  = 'T': transpose if entropy test indicates possibly faster
  convergence of Jacobi process if A^t is taken as input. If A is
  replaced with A^t, then the row pivoting is included automatically.
  = 'N': do not speculate.
  This option can be used to compute only the singular values, or the
  full SVD (U, SIGMA and V). For only one set of singular vectors
  (U or V), the caller should provide both U and V, as one of the
  matrices is used as workspace if the matrix A is transposed.
  The implementer can easily remove this constraint and make the
  code more complicated. See the descriptions of U and V.

JOBP
  JOBP is CHARACTER*1
  Issues the licence to introduce structured perturbations to drown
  denormalized numbers. This licence should be active if the
  denormals are poorly implemented, causing slow computation,
  especially in cases of fast convergence (!). For details see [1,2].
  For the sake of simplicity, this perturbations are included only
  when the full SVD or only the singular values are requested. The
  implementer/user can easily add the perturbation for the cases of
  computing one set of singular vectors.
  = 'P': introduce perturbation
  = 'N': do not perturb
```

```
M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A. M >= N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is DOUBLE PRECISION array, dimension (N)
  On exit,
  - For WORK(1)/WORK(2) = ONE: The singular values of A. During the
    computation SVA contains Euclidean column norms of the
    iterated matrices in the array A.
  - For WORK(1) .NE. WORK(2): The singular values of A are
    (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if
    sigma_max(A) overflows or if small singular values have been
    saved from underflow by scaling the input matrix A.
  - If JOBR='R' then some of the singular values may be returned
    as exact zeros obtained by "set to zero" because they are
    below the numerical rank threshold or are denormalized numbers.

U
  U is DOUBLE PRECISION array, dimension ( LDU, N )
  If JOBU = 'U', then U contains on exit the M-by-N matrix of
     the left singular vectors.
  If JOBU = 'F', then U contains on exit the M-by-M matrix of
     the left singular vectors, including an ONB
     of the orthogonal complement of the Range(A).
  If JOBU = 'W'  .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N),
     then U is used as workspace if the procedure
     replaces A with A^t. In that case, [V] is computed
     in U as left singular vectors of A^t and then
     copied back to the V array. This 'W' option is just
     a reminder to the caller that in this case U is
     reserved as workspace of length N*N.
  If JOBU = 'N'  U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U,  LDU >= 1.
  IF  JOBU = 'U' or 'F' or 'W',  then LDU >= M.
```

```
V
  V is DOUBLE PRECISION array, dimension ( LDV, N )
  If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of
     the right singular vectors;
  If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N),
     then V is used as workspace if the pprocedure
     replaces A with A^t. In that case, [U] is computed
     in V as right singular vectors of A^t and then
     copied back to the U array. This 'W' option is just
     a reminder to the caller that in this case V is
     reserved as workspace of length N*N.
  If JOBV = 'N'  V is not referenced.

LDV
  LDV is INTEGER
  The leading dimension of the array V,  LDV >= 1.
  If JOBV = 'V' or 'J' or 'W', then LDV >= N.

WORK
  WORK is DOUBLE PRECISION array, dimension at least LWORK.
  On exit, if N.GT.0 .AND. M.GT.0 (else not referenced),
  WORK(1) = SCALE = WORK(2) / WORK(1) is the scaling factor such
      that SCALE*SVA(1:N) are the computed singular values
      of A. (See the description of SVA().)
  WORK(2) = See the description of WORK(1).
  WORK(3) = SCONDA is an estimate for the condition number of
      column equilibrated A. (If JOBA .EQ. 'E' or 'G')
      SCONDA is an estimate of DSQRT(||(R^t * R)^(-1)||_1).
      It is computed using DPOCON. It holds
      N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA
      where R is the triangular factor from the QRF of A.
      However, if R is truncated and the numerical rank is
      determined to be strictly smaller than N, SCONDA is
      returned as -1, thus indicating that the smallest
      singular values might be lost.

  If full SVD is needed, the following two condition numbers are
  useful for the analysis of the algorithm. They are provied for
  a developer/implementer who is familiar with the details of
  the method.

  WORK(4) = an estimate of the scaled condition number of the
      triangular factor in the first QR factorization.
  WORK(5) = an estimate of the scaled condition number of the
      triangular factor in the second QR factorization.

  The following two parameters are computed if JOBT .EQ. 'T'.
  They are provided for a developer/implementer who is familiar
  with the details of the method.
```

```
  WORK(6) = the entropy of A^t*A :: this is the Shannon entropy
      of diag(A^t*A) / Trace(A^t*A) taken as point in the
      probability simplex.
  WORK(7) = the entropy of A*A^t.

LWORK
  LWORK is INTEGER
  Length of WORK to confirm proper allocation of work space.
  LWORK depends on the job:

  If only SIGMA is needed ( JOBU.EQ.'N', JOBV.EQ.'N' ) and
  -> .. no scaled condition estimate required (JOBE.EQ.'N'):
        LWORK >= max(2*M+N,4*N+1,7). This is the minimal requirement.
    ->> For optimal performance (blocked code) the optimal value
        is LWORK >= max(2*M+N,3*N+(N+1)*NB,7). Here NB is the optimal
        block size for DGEQP3 and DGEQRF.
        In general, optimal LWORK is computed as
        LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF), 7).
  -> .. an estimate of the scaled condition number of A is
        required (JOBA='E', 'G'). In this case, LWORK is the maximum
        of the above and N*N+4*N, i.e. LWORK >= max(2*M+N,N*N+4*N,7).
    ->> For optimal performance (blocked code) the optimal value
        is LWORK >= max(2*M+N,3*N+(N+1)*NB, N*N+4*N, 7).
        In general, the optimal length LWORK is computed as
        LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF),
                 N+N*N+LWORK(DPOCON),7).

  If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'),
  -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7).
  -> For optimal performance, LWORK >= max(2*M+N,3*N+(N+1)*NB,7),
     where NB is the optimal block size for DGEQP3, DGEQRF, DGELQ,
     DORMLQ. In general, the optimal length LWORK is computed as
     LWORK >= max(2*M+N,N+LWORK(DGEQP3), N+LWORK(DPOCON),
              N+LWORK(DGELQ), 2*N+LWORK(DGEQRF), N+LWORK(DORMLQ)).

  If SIGMA and the left singular vectors are needed
  -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7).
  -> For optimal performance:
     if JOBU.EQ.'U' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,7),
     if JOBU.EQ.'F' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,N+M*NB,7),
     where NB is the optimal block size for DGEQP3, DGEQRF, DORMQR.
     In general, the optimal length LWORK is computed as
     LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DPOCON),
                  2*N+LWORK(DGEQRF), N+LWORK(DORMQR)).
     Here LWORK(DORMQR) equals N*NB (for JOBU.EQ.'U') or
           M*NB (for JOBU.EQ.'F').

  If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and
  -> if JOBV.EQ.'V'
```

```
     the minimal requirement is LWORK >= max(2*M+N,6*N+2*N*N).
  -> if JOBV.EQ.'J' the minimal requirement is
     LWORK >= max(2*M+N, 4*N+N*N,2*N+N*N+6).
  -> For optimal performance, LWORK should be additionally
     larger than N+M*NB, where NB is the optimal block size for DORMQR.

IWORK
  IWORK is INTEGER array, dimension M+3*N.
  On exit,
  IWORK(1) = the numerical rank determined after the initial
             QR factorization with pivoting. See the descriptions
             of JOBA and JOBR.
  IWORK(2) = the number of the computed nonzero singular values
  IWORK(3) = if nonzero, a warning message:
             If IWORK(3).EQ.1 then some of the column norms of A
             were denormalized floats. The requested high accuracy
             is not warranted by the data.

INFO
  INFO is INTEGER
  < 0  : if INFO = -i, then the i-th argument had an illegal value.
  = 0 :  successfull exit;
  > 0 :  DGEJSV  did not converge in the maximal allowed number
         of sweeps. The computed values may be inaccurate.

Further Details:
  DGEJSV implements a preconditioned Jacobi SVD algorithm. It uses DGEQP3,
  DGEQRF, and DGELQF as preprocessors and preconditioners. Optionally, an
  additional row pivoting can be used as a preprocessor, which in some
  cases results in much higher accuracy. An example is matrix A with the
  structure A = D1 * C * D2, where D1, D2 are arbitrarily ill-conditioned
  diagonal matrices and C is well-conditioned matrix. In that case, complete
  pivoting in the first QR factorizations provides accuracy dependent on the
  condition number of C, and independent of D1, D2. Such higher accuracy is
  not completely understood theoretically, but it works well in practice.
  Further, if A can be written as A = B*D, with well-conditioned B and some
  diagonal D, then the high accuracy is guaranteed, both theoretically and
  in software, independent of D. For more details see [1], [2].
  The computational range for the singular values can be the full range
  ( UNDERFLOW,OVERFLOW ), provided that the machine arithmetic and the BLAS
  & LAPACK routines called by DGEJSV are implemented to work in that range.
  If that is not the case, then the restriction for safe computation with
  the singular values in the range of normalized IEEE numbers is that the
  spectral condition number kappa(A)=sigma_max(A)/sigma_min(A) does not
  overflow. This code (DGEJSV) is best used in this restricted range,
  meaning that singular values of magnitude below ||A||_2 / DLAMCH('O') are
  returned as zeros. See JOBR for details on this.
  Further, this implementation is somewhat slower than the one described
  in [1,2] due to replacement of some non-LAPACK components, and because
  the choice of some tuning parameters in the iterative part (DGESVJ) is
```

```
left to the implementer on a particular machine.
The rank revealing QR factorization (in this code: DGEQP3) should be
implemented as in [3]. We have a new version of DGEQP3 under development
that is more robust than the current one in LAPACK, with a cleaner cut in
rank defficient cases. It will be available in the SIGMA library [4].
If M is much larger than N, it is obvious that the inital QRF with
column pivoting can be preprocessed by the QRF without pivoting. That
well known trick is not used in DGEJSV because in some cases heavy row
weighting can be treated with complete pivoting. The overhead in cases
M much larger than N is then only due to pivoting, but the benefits in
terms of accuracy have prevailed. The implementer/user can incorporate
this extra QRF step easily. The implementer can also improve data movement
(matrix transpose, matrix copy, matrix transposed copy) - this
implementation of DGEJSV uses only the simplest, naive data movement.

SYNOPSIS
   Functions/Subroutines
       subroutine dgesdd (JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,
           LWORK, IWORK, INFO)
           DGESDD

Function/Subroutine Documentation
   subroutine dgesdd (character JOBZ, integer M, integer N, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( * ) S,
       double precision, dimension( ldu, * ) U, integer LDU, double precision,
       dimension( ldvt, * ) VT, integer LDVT, double precision, dimension( * )
       WORK, integer LWORK, integer, dimension( * ) IWORK, integer INFO)
       DGESDD

Purpose:
   DGESDD computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, optionally computing the left and right singular
   vectors.  If singular vectors are desired, it uses a
   divide-and-conquer algorithm.

   The SVD is written

   A = U * SIGMA * transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
   V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns VT = V**T, not V.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 JOBZ
```

```
  JOBZ is CHARACTER*1
  Specifies options for computing all or part of the matrix U:
  = 'A':  all M columns of U and all N rows of V**T are
          returned in the arrays U and VT;
  = 'S':  the first min(M,N) columns of U and the first
          min(M,N) rows of V**T are returned in the arrays U and VT;
  = 'O':  If M >= N, the first N columns of U are overwritten
          on the array A and all rows of V**T are returned in
          the array VT;
          otherwise, all columns of U are returned in the
          array U and the first M rows of V**T are overwritten
          in the array A;
  = 'N':  no columns of U or rows of V**T are computed.

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A

  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if JOBZ = 'O',  A is overwritten with the first N columns
                  of U (the left singular vectors, stored
                  columnwise) if M >= N;
                  A is overwritten with the first M rows
                  of V**T (the right singular vectors, stored
                  rowwise) otherwise.
  if JOBZ .ne. 'O', the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is DOUBLE PRECISION array, dimension (LDU,UCOL)
  UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N;
  UCOL = min(M,N) if JOBZ = 'S'.
  If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M
  orthogonal matrix U;
  if JOBZ = 'S', U contains the first min(M,N) columns of U
```

```
  (the left singular vectors, stored columnwise);
  if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT
  VT is DOUBLE PRECISION array, dimension (LDVT,N)
  If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the
  N-by-N orthogonal matrix V**T;
  if JOBZ = 'S', VT contains the first min(M,N) rows of
  V**T (the right singular vectors, stored rowwise);
  if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N;
  if JOBZ = 'S', LDVT >= min(M,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 1.
  If JOBZ = 'N', LWORK >= 3*min(M,N) + max(max(M,N),7*min(M,N)).
  If JOBZ = 'O', LWORK >= 3*min(M,N) +
                 max(max(M,N),5*min(M,N)*min(M,N)+4*min(M,N)).
  If JOBZ = 'S' or 'A' LWORK >= min(M,N)*(7+4*min(M,N))
  For good performance, LWORK should generally be larger.
  If LWORK = -1 but other input arguments are legal, WORK(1)
  returns the optimal LWORK.

IWORK
  IWORK is INTEGER array, dimension (8*min(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  DBDSDC did not converge, updating process failed.
```
