=====

UnivariateSkewPolynomial examples

=====

Skew or Ore polynomial rings provide a unified framework to compute with differential and difference equations.

In the following, let A be an integral domain, equipped with two endomorphisms σ and δ where:

$\sigma: A \rightarrow A$ is an injective ring endomorphism
 $\delta: A \rightarrow A$, the pseudo-derivation with respect to σ ,
 is an additive endomorphism with

$$\delta(ab) = \sigma(a)\delta(b) + \delta(a)b$$
 for all a, b in A

Note that in the domains and categories below, these properties are not checked.

The skew polynomial ring $[\Delta; \sigma, \delta]$ is the ring of polynomials in Δ with coefficients in A , with the usual addition, while the product is given by

$$\Delta a = \sigma(a)\Delta + \delta(a) \text{ for } a \text{ in } A$$

The two most important examples of skew polynomial rings are:

$K(x)[D, 1, \delta]$, where 1 is the identity on K and δ is
 the usual derivative, is the ring of differential
 polynomials

$K[E, n, \text{mapsto } n+1, 0]$ is the ring of linear recurrence operators
 n with polynomial coefficients

For example,

The `UnivariateSkewPolynomialCategory` (OREPCAT) provides a unified framework for polynomial rings in a non-central indeterminate over some coefficient ring R . The commutation relations between the indeterminate x and the coefficient t is given by

$$x r = \sigma(r) x + \delta(r)$$

where σ is a ring endomorphism of R
 and δ is a σ -derivation of R
 which is an additive map from R to R such that

$$\delta(rs) = \sigma(r) \delta(s) + \delta(r) s$$

In case σ is the identity map on R , a σ -derivation of R is just called a derivation. Here are some examples

We start with a linear ordinary differential operator. First, we define the coefficient ring to be expressions in one variable x

with fractional coefficients:

F:=EXPR(FRAC(INT))

Define Dx to be a derivative d/dx:

Dx:F->F:=f+-->D(f,['x])

Define a skew polynomial ring over F with identity endomorphism as
 \sigma and derivation d/dx as \delta:

D0:=OREUP('d,F,1,Dx)

u:D0:=(operator 'u)(x)

d:D0:='d

a:D0:=u^3*d^3+u^2*d^2+u*d+1

$$u(x)^3 d^3 + u(x)^2 d^2 + u(x) d + 1$$

b:D0:=(u+1)*d^2+2*d

$$(u(x) + 1) d^2 + 2d$$

r:=rightDivide(a,b)

$$\begin{aligned} \text{[quotient]} &= \frac{u(x)^3}{u(x) + 1} d + \frac{-u(x)^3 u(x) - u(x)^3 + u(x)^2}{u(x)^2 + 2u(x) + 1}, \\ \text{remainder} &= \frac{2u(x)^3 u(x) + 3u(x)^3 + u(x)^3}{u(x)^2 + 2u(x) + 1} d + 1 \end{aligned}$$

r.quotient

$$\frac{u(x)^3}{u(x) + 1} d + \frac{-u(x)^3 u(x) - u(x)^3 + u(x)^2}{2}$$

$$u(x)^2 + 2u(x) + 1$$

r.remainder

$$\frac{2u(x)^3 u'(x) + 3u(x)^2 u'(x)^2 + u(x)^3}{u(x)^2 + 2u(x) + 1} d + 1$$

)clear all

As a second example, we consider the so-called Weyl algebra.

Define the coefficient ring to be an ordinary polynomial over integers in one variable t

R:=UP('t,INT)

Define a skew polynomial ring over R with identity map as \sigma and derivation d/dt as \delta. The resulting algebra is then called a Weyl algebra. This is a simple ring over a division ring that is non-commutative, similar to the ring of matrices.

W:=OREUP('x,R,1,D)

t:W:='t

x:W:='x

Let

a:W:=(t-1)*x^4+(t^3+3*t+1)*x^2+2*t*x+t^3

$$(t-1)x^4 + (t^3 + 3t + 1)x^2 + 2tx + t^3$$

b:W:=(6*t^4+2*t^2)*x^3+3*t^2*x^2

$$(6t^4 + 2t^2)x^3 + 3t^2x^2$$

Then

a*b

```

      5      4      3      2 7      4      3      2      6
      (6t  - 6t  + 2t  - 2t )x  + (96t  - 93t  + 13t  - 16t)x
+
      7      5      4      3      2      5
      (6t  + 20t  + 6t  + 438t  - 406t  - 24)x
+
      6      5      4      3      2      4
      (48t  + 15t  + 152t  + 61t  + 603t  - 532t - 36)x
+
      7      5      4      3      2      3
      (6t  + 74t  + 60t  + 226t  + 116t  + 168t - 140)x
+
      5      3      2      2
      (3t  + 6t  + 12t  + 18t + 6)x

a^3
      3      2      12      5      4      3      2      10
      (t  - 3t  + 3t - 1)x  + (3t  - 6t  + 12t  - 15t  + 3t + 3)x
+
      3      2      9      7      6      5      4      3      2      8
      (6t  - 12t  + 6t)x  + (3t  - 3t  + 21t  - 18t  + 24t  - 9t  - 15t - 3)x
+
      5      4      3      2      7
      (12t  - 12t  + 36t  - 24t  - 12t)x
+
      9      7      6      5      4      3      2      6
      (t  + 15t  - 3t  + 45t  + 6t  + 36t  + 15t  + 9t + 1)x
+
      7      5      3      2      5
      (6t  + 48t  + 54t  + 36t  + 6t)x
+
      9      7      6      5      4      3      2 4
      (3t  + 21t  + 3t  + 39t  + 18t  + 39t  + 12t )x
+
      7      5      4      3 3      9      7      6      5 2      7      9
      (12t  + 36t  + 12t  + 8t )x  + (3t  + 9t  + 3t  + 12t )x  + 6t x + t

```

```

)clear all

```

As a third example, we construct a difference operator algebra over the ring of `EXPR(INT)` by using an automorphism `S` defined by a "shift" operation `S:EXPR(INT) -> EXPR(INT)`

```

s(e)(n) = e(n+1)

```

and an `S`-derivation defined by `DF:EXPR(INT) -> EXPR(INT)` as

$$DF(e)(n) = e(n+1) - e(n)$$

Define S to be a "shift" operator, which acts on expressions with the discrete variable n:

$$S: \text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT}) := e \mapsto \text{eval}(e, [n], [n+1])$$

Define DF to be a "difference" operator, which acts on expressions with a discrete variable n:

$$DF: \text{EXPR}(\text{INT}) \rightarrow \text{EXPR}(\text{INT}) := e \mapsto \text{eval}(e, [n], [n+1]) - e$$

Then define the difference operator algebra D0:

$$D0 := \text{OREUP}('D, \text{EXPR}(\text{INT}), \text{morphism } S, DF)$$

$$u := (\text{operator } 'u)[n]$$

$$L: D0 := 'D + u$$

$$D + u(n)$$

$$L^2$$

$$D^2 + 2u(n)D + u(n)^2$$

```
)clear all
```

As a fourth example, we construct a skew polynomial ring by using an inner derivation δ induced by a fixed y in R :

$$\delta(r) = yr - ry$$

First we should expose the constructor SquareMatrix so it is visible in the interpreter:

```
)set expose add constructor SquareMatrix
```

Define R to be the square matrix with integer entries:

$$R := \text{SQMATRIX}(2, \text{INT})$$

$$y: R := \text{matrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$

Define the inner derivative \delta:

```
delta:R->R:=r+>y*r-r*y
```

Define S to be a skew polynomial determined by \sigma = 1
and \delta as an inner derivative:

```
S:=OREUP('x,R,1,delta)
```

```
x:S:='x
```

```
a:S:=matrix [[2,3],[1,1]]
```

```
+2 3+
|   |
+1 1+
```

```
x^2*a
```

```
+2 3+ 2 +2 - 2+ +0 - 2+
|   |x + |   |x + |   |
+1 1+ +0 - 2+ +0 0 +
```

UnivariateTaylorSeries examples
=====

```

Dense Taylor series in one variable. `UnivariateTaylorSeries` is a domain representing Taylor series in one variable with coefficients in an arbitrary ring. The parameters of the type specify the coefficient ring, the power series variable, and the center of the power series expansion. For example, `UnivariateTaylorSeries(Integer, x, 3)` represents Taylor series in $(x - 3)$ with Integer coefficients.

++ Description:
++ Dense Taylor series in one variable
++ \spadtype{UnivariateTaylorSeries} is a domain representing Taylor
++ series in
++ one variable with coefficients in an arbitrary ring. The parameters
++ of the type specify the coefficient ring, the power series variable,
++ and the center of the power series expansion. For example,
++ \spadtype{UnivariateTaylorSeries}(Integer,x,3) represents
++ Taylor series in
++ \spad{(x - 3)} with \spadtype{Integer} coefficients.

UnivariateTaylorSeries(Coef,var,cen) : SIG == CODE where
  Coef : Ring
  var : Symbol
  cen : Coef

  I    ==> Integer
  NNI  ==> NonNegativeInteger
  P    ==> Polynomial Coef
  RN   ==> Fraction Integer
  ST   ==> Stream
  STT  ==> StreamTaylorSeriesOperations Coef
  TERM ==> Record(k:NNI,c:Coef)
  UP   ==> UnivariatePolynomial(var,Coef)

SIG ==> UnivariateTaylorSeriesCategory(Coef) with

  coerce : UP -> %
    ++\spad{coerce(p)} converts a univariate polynomial p in the variable
    ++\spad{var} to a univariate Taylor series in \spad{var}.

  univariatePolynomial : (% ,NNI) -> UP
    ++\spad{univariatePolynomial(f,k)} returns a univariate polynomial
    ++ consisting of the sum of all terms of f of degree \spad{<= k}.

  coerce : Variable(var) -> %
    ++\spad{coerce(var)} converts the series variable \spad{var} into a
    ++ Taylor series.

  differentiate : (% ,Variable(var)) -> %
    ++ \spad{differentiate(f(x),x)} computes the derivative of
    ++ \spad{f(x)} with respect to \spad{x}.

  lagrange : % -> %
    ++\spad{lagrange(g(x))} produces the Taylor series for \spad{f(x)}
    ++ where \spad{f(x)} is implicitly defined as \spad{f(x) = x*g(f(x))}.

  lambert : % -> %
    ++\spad{lambert(f(x))} returns \spad{f(x) + f(x^2) + f(x^3) + ...}.
    ++ This function is used for computing infinite products.

```

```

++ \spad{f(x)} should have zero constant coefficient.
++ If \spad{f(x)} is a Taylor series with constant term 1, then
++ \spad{product(n = 1..infinity,f(x^n)) = exp(log(lambert(f(x))))}.

oddlambert : % -> %
++\spad{oddlambert(f(x))} returns \spad{f(x) + f(x^3) + f(x^5) + ...}.
++ \spad{f(x)} should have a zero constant coefficient.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a Taylor series with constant term 1, then
++ \spad{product(n=1..infinity,f(x^(2*n-1)))=exp(log(oddlambert(f(x))))}.

evenlambert : % -> %
++\spad{evenlambert(f(x))} returns \spad{f(x^2) + f(x^4) + f(x^6) + ...}.
++ \spad{f(x)} should have a zero constant coefficient.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a Taylor series with constant term 1, then
++ \spad{product(n=1..infinity,f(x^(2*n))) = exp(log(evenlambert(f(x))))}

generalLambert : (% ,I,I) -> %
++\spad{generalLambert(f(x),a,d)} returns \spad{f(x^a) + f(x^(a + d)) +
++ f(x^(a + 2 d)) + ... }. \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and d should be positive.

revert : % -> %
++ \spad{revert(f(x))} returns a Taylor series \spad{g(x)} such that
++ \spad{f(g(x)) = g(f(x)) = x}. Series \spad{f(x)} should have constant
++ coefficient 0 and 1st order coefficient 1.

multisect : (I,I,%) -> %
++\spad{multisect(a,b,f(x))} selects the coefficients of
++ \spad{x^((a+b)*n+a)}, and changes this monomial to \spad{x^n}.

invmultisect : (I,I,%) -> %
++\spad{invmultisect(a,b,f(x))} substitutes \spad{x^((a+b)*n)}
++ for \spad{x^n} and multiples by \spad{x^b}.

if Coef has Algebra Fraction Integer then

integrate : (% ,Variable(var)) -> %
++ \spad{integrate(f(x),x)} returns an anti-derivative of the power
++ series \spad{f(x)} with constant coefficient 0.
++ We may integrate a series when we can divide coefficients
++ by integers.

```

```

coerce : UP -> %
  ++\spad{coerce(p)} converts a univariate polynomial p in the variable
  ++\spad{var} to a univariate Taylor series in \spad{var}.

univariatePolynomial : (%,NNI) -> UP
  ++\spad{univariatePolynomial(f,k)} returns a univariate polynomial
  ++ consisting of the sum of all terms of f of degree \spad{<= k}.

coerce : Variable(var) -> %
  ++\spad{coerce(var)} converts the series variable \spad{var} into a
  ++ Taylor series.

differentiate : (%,Variable(var)) -> %
  ++ \spad{differentiate(f(x),x)} computes the derivative of
  ++ \spad{f(x)} with respect to \spad{x}.

lagrange : % -> %
  ++\spad{lagrange(g(x))} produces the Taylor series for \spad{f(x)}
  ++ where \spad{f(x)} is implicitly defined as \spad{f(x) = x*g(f(x))}.

lambert : % -> %
  ++\spad{lambert(f(x))} returns \spad{f(x) + f(x^2) + f(x^3) + ...}.
  ++ This function is used for computing infinite products.
  ++ \spad{f(x)} should have zero constant coefficient.
  ++ If \spad{f(x)} is a Taylor series with constant term 1, then
  ++ \spad{product(n = 1..infinity,f(x^n)) = exp(log(lambert(f(x))))}.

oddlambert : % -> %
  ++\spad{oddlambert(f(x))} returns \spad{f(x) + f(x^3) + f(x^5) + ...}.
  ++ \spad{f(x)} should have a zero constant coefficient.
  ++ This function is used for computing infinite products.
  ++ If \spad{f(x)} is a Taylor series with constant term 1, then
  ++ \spad{product(n=1..infinity,f(x^(2*n-1)))=exp(log(oddlambert(f(x))))}.

evenlambert : % -> %
  ++\spad{evenlambert(f(x))} returns \spad{f(x^2) + f(x^4) + f(x^6) + ...}.
  ++ \spad{f(x)} should have a zero constant coefficient.
  ++ This function is used for computing infinite products.
  ++ If \spad{f(x)} is a Taylor series with constant term 1, then
  ++ \spad{product(n=1..infinity,f(x^(2*n)))=exp(log(evenlambert(f(x))))}.

generalLambert : (%,I,I) -> %
  ++\spad{generalLambert(f(x),a,d)} returns \spad{f(x^a) + f(x^(a + d)) +
  ++ f(x^(a + 2 d)) + ... }. \spad{f(x)} should have zero constant
  ++ coefficient and \spad{a} and d should be positive.

revert : % -> %
  ++ \spad{revert(f(x))} returns a Taylor series \spad{g(x)} such that
  ++ \spad{f(g(x)) = g(f(x)) = x}. Series \spad{f(x)} should have constant

```

```

++ coefficient 0 and 1st order coefficient 1.

multisect : (I,I,%) -> %
++\spad{multisect(a,b,f(x))} selects the coefficients of
++ \spad{x^((a+b)*n+a)}, and changes this monomial to \spad{x^n}.

invmultisect : (I,I,%) -> %
++\spad{invmultisect(a,b,f(x))} substitutes \spad{x^((a+b)*n)}
++ for \spad{x^n} and multiplies by \spad{x^b}.

if Coef has Algebra Fraction Integer then

integrate : (%,Variable(var)) -> %
++ \spad{integrate(f(x),x)} returns an anti-derivative of the power
++ series \spad{f(x)} with constant coefficient 0.
++ We may integrate a series when we can divide coefficients
++ by integers.

— UniversalSegment.help —

===== UniversalSegment examples =====

The UniversalSegment domain generalizes Segment by allowing segments without a "hi" end point.

```
pints := 1..
      1..
```

Type: UniversalSegment PositiveInteger

```
nevens := (0..) by -2
      0.. by - 2
```

Type: UniversalSegment NonNegativeInteger

Values of type Segment are automatically converted to type UniversalSegment when appropriate.

```
useg: UniversalSegment(Integer) := 3..10
      3..10
```

Type: UniversalSegment Integer

The operation hasHi is used to test whether a segment has a hi end point.

```
hasHi pints
      false
```

Type: Boolean

```
hasHi nevens
      false
```

Type: Boolean

```
hasHi useg
      true
```

Type: Boolean

All operations available on type Segment apply to UniversalSegment, with the proviso that expansions produce streams rather than lists. This is to accommodate infinite expansions.

```
expand pints
      [1,2,3,4,5,6,7,8,9,10,...]
```

Type: Stream Integer

```
expand nevens
      [0,- 2,- 4,- 6,- 8,- 10,- 12,- 14,- 16,- 18,...]
```

Type: Stream Integer

```

expand [1, 3, 10..15, 100..]
      [1,3,10,11,12,13,14,15,100,101,...]
                                     Type: Stream Integer

```

— Vector.help —

===== Vector examples =====

The Vector domain is used for storing data in a one-dimensional indexed data structure. A vector is a homogeneous data structure in that all the components of the vector must belong to the same Axiom domain. Each vector has a fixed length specified by the user; vectors are not extensible. This domain is similar to the OneDimensionalArray domain, except that when the components of a Vector belong to a Ring, arithmetic operations are provided.

As with the OneDimensionalArray domain, a Vector can be created by calling the operation new, its components can be accessed by calling the operations elt and qelt, and its components can be reset by calling the operations setelt and qsetelt.

This creates a vector of integers of length 5 all of whose components are 12.

```
u : VECTOR INT := new(5,12)
[12,12,12,12,12]
Type: Vector Integer
```

This is how you create a vector from a list of its components.

```
v : VECTOR INT := vector([1,2,3,4,5])
[1,2,3,4,5]
Type: Vector Integer
```

Indexing for vectors begins at 1. The last element has index equal to the length of the vector, which is computed by #.

```
 #(v)
  5
Type: PositiveInteger
```

This is the standard way to use elt to extract an element. Functionally, it is the same as if you had typed elt(v,2).

```
 v.2
  2
Type: PositiveInteger
```

This is the standard way to use setelt to change an element. It is the same as if you had typed setelt(v,3,99).

```
 v.3 := 99
```

99

Type: PositiveInteger

Now look at `v` to see the change. You can use `qelt` and `qsetelt` (instead of `elt` and `setelt`, respectively) but only when you know that the index is within the valid range.

```
v
[1,2,99,4,5]
```

Type: Vector Integer

When the components belong to a Ring, Axiom provides arithmetic operations for Vector. These include left and right scalar multiplication.

```
5 * v
[5,10,495,20,25]
```

Type: Vector Integer

```
v * 7
[7,14,693,28,35]
```

Type: Vector Integer

```
w : VECTOR INT := vector([2,3,4,5,6])
[2,3,4,5,6]
```

Type: Vector Integer

Addition and subtraction are also available.

```
v + w
[3,5,103,9,11]
```

Type: Vector Integer

Of course, when adding or subtracting, the two vectors must have the same length or an error message is displayed.

```
v - w
[- 1,- 1,95,- 1,- 1]
```

Type: Vector Integer

 — Void.help —

===== Void examples =====

When an expression is not in a value context, it is given type Void.
For example, in the expression

```
r := (a; b; if c then d else e; f)
```

values are used only from the subexpressions c and f: all others are thrown away. The subexpressions a, b, d and e are evaluated for side-effects only and have type Void. There is a unique value of type Void.

You will most often see results of type Void when you declare a variable.

```
a : Integer
```

Type: Void

Usually no output is displayed for Void results. You can force the display of a rather ugly object by issuing

```
)set message void on
```

```
b : Fraction Integer
                                     Type: Void
```

```
)set message void off
```

All values can be converted to type Void.

```
3::Void
                                     Type: Void
```

Once a value has been converted to Void, it cannot be recovered.

```
% :: PositiveInteger
  Cannot convert from type Void to PositiveInteger for value "()"
```

=====
WuWenTsunTriangularSet examples
=====
```

The WuWenTsunTriangularSet domain constructor implements the characteristic set method of Wu Wen Tsun. This algorithm computes a list of triangular sets from a list of polynomials such that the algebraic variety defined by the given list of polynomials decomposes into the union of the regular-zero sets of the computed triangular sets. The constructor takes four arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category IntegralDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. The third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The last one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The abbreviation for WuWenTsunTriangularSet is WUTSET.

Let us illustrate the facilities by an example.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and make it an ordered set;

```
V := OVAR(ls)
OrderedVariableList [x,y,z,t]
Type: Domain
```

then define the exponent monoid.

```
E := IndexedExponents V
IndexedExponents OrderedVariableList [x,y,z,t]
Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t])
Type: Domain
```

Let the variables be polynomial.

```

x: P := 'x
  x
  Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

y: P := 'y
  y
  Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

z: P := 'z
  z
  Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

t: P := 't
  t
  Type: NewSparseMultivariatePolynomial(Integer,
    OrderedVariableList [x,y,z,t])

```

Now call the WuWenTsunTriangularSet domain constructor.

```

T := WUTSET(R,E,V,P)
WuWenTsunTriangularSet(Integer,IndexedExponents OrderedVariableList [x,y,z,t]
,OrderedVariableList [x,y,z,t],NewSparseMultivariatePolynomial(Integer,OrderedVariableList [x,y,z,t]))
Type: Domain

```

Define a polynomial system.

```

p1 := x ** 31 - x ** 6 - x - y
      31      6
      x  - x  - x - y
      Type: NewSparseMultivariatePolynomial(Integer,
        OrderedVariableList [x,y,z,t])

p2 := x ** 8 - z
      8
      x  - z
      Type: NewSparseMultivariatePolynomial(Integer,
        OrderedVariableList [x,y,z,t])

p3 := x ** 10 - t
      10
      x  - t
      Type: NewSparseMultivariatePolynomial(Integer,
        OrderedVariableList [x,y,z,t])

```

```
lp := [p1, p2, p3]
      31      6      8      10
[x  - x  - x  - y, x  - z, x  - t]
      Type: List NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])
```

Compute a characteristic set of the system.

```
characteristicSet(lp)$T
      5      4 4 2 2      3 4      7      4      6      6      3      3      3      3
{z  - t , t z y + 2t z y + (- t + 2t - t)z + t z, (t - 1)z x - z y - t }
      Type: Union(WuWenTsunTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t])),...)

```

Solve the system.

```
zeroSetSplit(lp)$T
      3      5      4 3      3      2
[{t,z,y,x}, {t - 1, z - t , z y + t , z x - t },
      5      4 4 2 2      3 4      7      4      6      6      3      3      3      3
{z  - t , t z y + 2t z y + (- t + 2t - t)z + t z, (t - 1)z x - z y - t }]
      Type: List WuWenTsunTriangularSet(Integer,
      IndexedExponents OrderedVariableList [x,y,z,t],
      OrderedVariableList [x,y,z,t],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [x,y,z,t]))

```

The RegularTriangularSet and SquareFreeRegularTriangularSet domain constructors, the LazardSetSolvingPackage package constructors as well as, SquareFreeRegularTriangularSet and ZeroDimensionalSolvePackage package constructors also provide operations to compute triangular decompositions of algebraic varieties. These five constructor use a special kind of characteristic sets, called regular triangular sets. These special characteristic sets have better properties than the general ones. Regular triangular sets and their related concepts are presented in the paper "On the Theories of Triangular sets" By P. Aubry, D. Lazard and M. Moreno Maza (to appear in the Journal of Symbolic Computation). The decomposition algorithm (due to the third author) available in the four above constructors provide generally better timings than the characteristic set method. In fact, the WUTSET constructor remains interesting for the purpose of manipulating characteristic sets whereas the other constructors are more convenient for solving polynomial systems.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

— domain WUTSET WuWenTsunTriangularSet —

```
)abbrev domain WUTSET WuWenTsunTriangularSet
++ Author: Marc Moreno Maza (marc@nag.co.uk)
```

```

++ Date Created: 11/18/1995
++ Date Last Updated: 12/15/1998
++ References :
++ [1] W. T. WU "A Zero Structure Theorem for polynomial equations solving"
++     MM Research Preprints, 1987.
++ [2] D. M. WANG "An implementation of the characteristic set method in Maple"
++     Proc. DISCO'92. Bath, England.
++ Description:
++ A domain constructor of the category \axiomType{GeneralTriangularSet}.
++ The only requirement for a list of polynomials to be a member of such
++ a domain is the following: no polynomial is constant and two distinct
++ polynomials have distinct main variables. Such a triangular set may
++ not be auto-reduced or consistent. The construct operation
++ does not check the previous requirement. Triangular sets are stored
++ as sorted lists w.r.t. the main variables of their members.
++ Furthermore, this domain exports operations dealing with the
++ characteristic set method of Wu Wen Tsun and some optimizations
++ mainly proposed by Dong Ming Wang.

```

```

WuWenTsunTriangularSet(R,E,V,P) : SIG == CODE where

```

```

  R : IntegralDomain
  E : OrderedAbelianMonoidSup
  V : OrderedSet

SIG ==> TriangularSetCategory(R,E,V,P) with

```

```

  medialSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
  ++ \axiom{medialSet(ps,redOp?,redOp)} returns \axiom{bs} a basic set
  ++ (in Wu Wen Tsun sense w.r.t the reduction-test \axiom{redOp?})
  ++ of some set generating the same ideal as \axiom{ps} (with
  ++ rank not higher than any basic set of \axiom{ps}), if no non-zero
  ++ constant polynomials appear during the computations, else
  ++ \axiom{"failed"} is returned. In the former case, \axiom{bs} has to
  ++ be understood as a candidate for being a characteristic set of

```

```

++ \axiom{ps}. In the original algorithm, \axiom{bs} is simply a basic
++ set of \axiom{ps}.

medialSet : LP -> Union($,"failed")
++ \axiom{medial(ps)} returns the same as
++ \axiom{medialSet(ps,initiallyReduced?,initiallyReduce)}.

characteristicSet : (LP,((P,P)->B),((P,P)->P)) -> Union($,"failed")
++ \axiom{characteristicSet(ps,redOp?,redOp)} returns a
++ non-contradictory characteristic set of \axiom{ps} in
++ Wu Wen Tsun sense w.r.t the
++ reduction-test \axiom{redOp?} (using \axiom{redOp} to reduce
++ polynomials w.r.t a \axiom{redOp?} basic set), if no
++ non-zero constant polynomial appear during those reductions,
++ else \axiom{"failed"} is returned.
++ The operations \axiom{redOp} and \axiom{redOp?} must satisfy
++ the following conditions: \axiom{redOp?(redOp(p,q),q)} holds
++ for every polynomials \axiom{p,q} and there exists an integer
++ \axiom{e} and a polynomial \axiom{f} such that we have
++ \axiom{init(q)^e*p = f*q + redOp(p,q)}.

characteristicSet : LP -> Union($,"failed")
++ \axiom{characteristicSet(ps)} returns the same as
++ \axiom{characteristicSet(ps,initiallyReduced?,initiallyReduce)}.

characteristicSerie : (LP,((P,P)->B),((P,P)->P)) -> List $
++ \axiom{characteristicSerie(ps,redOp?,redOp)} returns a list
++ \axiom{lts}
++ of triangular sets such that the zero set of \axiom{ps} is the
++ union of the regular zero sets of the members of \axiom{lts}.
++ This is made by the Ritt and Wu Wen Tsun process applying
++ the operation \axiom{characteristicSet(ps,redOp?,redOp)}
++ to compute characteristic sets in Wu Wen Tsun sense.

characteristicSerie : LP -> List $
++ \axiom{characteristicSerie(ps)} returns the same as
++ \axiom{characteristicSerie(ps,initiallyReduced?,initiallyReduce)}.

domain XDPOLY XDistributedPolynomial

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructor **XDistributedPolynomial** provide a distributed representation for these polynomials. It is the non-commutative equivalent for the **DistributedMultivariatePolynomial** constructor.

XPBWPolynomial examples

=====

This domain constructor implements polynomials in non-commutative variables written in the Poincare-Birkhoff-Witt basis from the Lyndon basis.

These polynomials can be used to compute Baker-Campbell-Hausdorff relations.

=====

XPolynomial examples

=====

The XPolynomial domain constructor implements multivariate polynomials whose set of variables is Symbol. These variables do not commute. The only parameter of this constructor is the coefficient ring which may be non-commutative. However, coefficients and variables commute. The representation of the polynomials is recursive. The abbreviation for XPolynomial is XPOLY.

Other constructors like XPolynomialRing, XRecursivePolynomial as well as XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPOLY domain constructor.

Define a polynomial ring over the integers.

```

poly := XPolynomial(Integer)
      XPolynomial Integer
                                Type: Domain

```

Define a first polynomial,

```
pr: poly := 2*x + 3*y-5
      - 5 + x 2 + y 3
```

Type: XPolynomial Integer

and a second one.

```
pr2: poly := pr*pr
      25 + x(- 20 + x 4 + y 6) + y(- 30 + x 6 + y 9)
```

Type: XPolynomial Integer

Rewrite pr in a distributive way,

```
pd := expand pr
      - 5 + 2x + 3y
```

Type: XDistributedPolynomial(Symbol,Integer)

compute its square,

```
pd2 := pd*pd
      2          2
      25 - 20x - 30y + 4x  + 6x y + 6y x + 9y
```

Type: XDistributedPolynomial(Symbol,Integer)

and checks that:

```
expand(pr2) - pd2
      0
```

Type: XDistributedPolynomial(Symbol,Integer)

We define:

```
qr := pr**3
      - 125 + x(150 + x(- 60 + x 8 + y 12) + y(- 90 + x 12 + y 18))
      +
      y(225 + x(- 90 + x 12 + y 18) + y(- 135 + x 18 + y 27))
```

Type: XPolynomial Integer

and:

```
qd := pd**3
      2          2          3          2
      - 125 + 150x + 225y - 60x  - 90x y - 90y x - 135y  + 8x  + 12x y + 12x y x
      +
      2          2          2          3
      18x y  + 12y x  + 18y x y + 18y x + 27y
```

Type: XDistributedPolynomial(Symbol,Integer)

We truncate qd at degree 3.

```
trunc(qd,2)
      2      2
- 125 + 150x + 225y - 60x  - 90x y - 90y x - 135y
Type: XDistributedPolynomial(Symbol,Integer)
```

The same for qr:

```
trunc(qr,2)
- 125 + x(150 + x(- 60) + y(- 90)) + y(225 + x(- 90) + y(- 135))
Type: XPolynomial Integer
```

We define:

```
Word := OrderedFreeMonoid Symbol
OrderedFreeMonoid Symbol
Type: Domain
```

and:

```
w: Word := x*y**2
      2
x y
Type: OrderedFreeMonoid Symbol
```

We can compute the right-quotient of qr by r:

```
rquo(qr,w)
      18
Type: XPolynomial Integer
```

and the shuffle-product of pr by r:

```
sh(pr,w::poly)
x(x y y 4 + y(x y 2 + y(- 5 + x 2 + y 9))) + y x y y 3
Type: XPolynomial Integer
```

)abbrev domain XPOLY XPolynomial
++ Author: Michel Petitot petitot@lifl.fr
++ Date Created: 91
++ Date Last Updated: 7 Juillet 92
++ Description:
++ This type supports multivariate polynomials whose set of variables
++ is \spadtype{Symbol}. The representation is recursive.
++ The coefficient ring may be non-commutative and the variables
++ do not commute. However, coefficients and variables commute.

```

=====

XPolynomialRing examples

=====

The XPolynomialRing domain constructor implements generalized polynomials with coefficients from an arbitrary Ring (not necessarily commutative) and whose exponents are words from an arbitrary OrderedMonoid (not necessarily commutative too). Thus these polynomials are (finite) linear combinations of words.

This constructor takes two arguments. The first one is a Ring and the second is an OrderedMonoid. The abbreviation for XPolynomialRing is XPR.

Other constructors like XPolynomial, XRecursivePolynomial, XDistributedPolynomial, LiePolynomial and XPBWPolynomial implement multivariate polynomials in non-commutative variables.

We illustrate now some of the facilities of the XPR domain constructor.

Define the free ordered monoid generated by the symbols.

```

Word := OrderedFreeMonoid(Symbol)
      OrderedFreeMonoid Symbol
                                Type: Domain

```

Define the linear combinations of these words with integer coefficients.

```

poly:= XPR(Integer,Word)
      XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
                                Type: Domain

```

Then we define a first element from poly.

```
p:poly := 2 * x - 3 * y + 1
      1 + 2x - 3y
Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

And a second one.

```
q:poly := 2 * x + 1
      1 + 2x
Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

We compute their sum,

```
p + q
      2 + 4x - 3y
Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

their product,

```
p * q
      2
      1 + 4x - 3y + 4x - 6y x
Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

and see that variables do not commute.

```
(p+q)**2-p**2-q**2-2*p*q
      - 6x y + 6y x
Type: XPolynomialRing(Integer,OrderedFreeMonoid Symbol)
```

Now we define a ring of square matrices,

```
M := SquareMatrix(2,Fraction Integer)
      SquareMatrix(2,Fraction Integer)
Type: Domain
```

and the linear combinations of words with these matrices as coefficients.

```
poly1:= XPR(M,Word)
      XPolynomialRing(SquareMatrix(2,Fraction Integer),OrderedFreeMonoid Symbol)
Type: Domain
```

Define a first matrix,

```
m1:M := matrix [ [i*j**2 for i in 1..2] for j in 1..2]
      +1  2+
      |   |
      +4  8+
Type: SquareMatrix(2,Fraction Integer)
```

a second one,

```

m2:M := m1 - 5/4
      + 1      +
      |- - 2 |
      | 4      |
      |        |
      |      27|
      | 4      --|
      +      4+
                                     Type: SquareMatrix(2,Fraction Integer)

```

and a third one.

```

m3: M := m2**2
      +129      +
      |--- 13 |
      | 16      |
      |        |
      |      857|
      |26      ---|
      +      16+
                                     Type: SquareMatrix(2,Fraction Integer)

```

Define a polynomial,

```

pm:poly1 := m1*x + m2*y + m3*z - 2/3
      + 2      +      + 1      +      +129      +
      |- - 0 |      |- - 2 |      |--- 13 |
      | 3      |      +1 2+      | 4      |      | 16      |
      |        | + |      |x + |      |y + |      |z
      |      2|      +4 8+      |      27|      |      857|
      | 0      - -|      | 4      --|      |26      ---|
      +      3+      +      4+      +      16+
      Type: XPolynomialRing(SquareMatrix(2,Fraction Integer),
                             OrderedFreeMonoid Symbol)

```

a second one,

```

qm:poly1 := pm - m1*x
      + 2      +      + 1      +      +129      +
      |- - 0 |      |- - 2 |      |--- 13 |
      | 3      |      | 4      |      | 16      |
      |        | + |      |y + |      |z
      |      2|      |      27|      |      857|
      | 0      - -|      | 4      --|      |26      ---|
      +      3+      +      4+      +      16+
      Type: XPolynomialRing(SquareMatrix(2,Fraction Integer),
                             OrderedFreeMonoid Symbol)

```

and the following power.

```

qm**3

=====
XRecursivePolynomial examples
=====
```

This type supports multivariate polynomials whose variables do not commute. The representation is recursive. The coefficient ring may be non-commutative. Coefficients and variables commute.

See Also:

```
o )show XRecursivePolynomial
```

Polynomial arithmetic with non-commutative variables has been improved by a contribution of Michel Petitot (University of Lille I, France). The domain constructors **XRecursivePolynomial** provides a recursive for these polynomials. It is the non-commutative equivalents for the **SparseMultivariatePolynomial** constructor.

DFLOAT.lsp BOOTSTRAP

DFLOAT depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **DFLOAT** category which we can write into the **MID** directory. We compile the lisp code and copy the **DFLOAT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— DFLOAT.lsp BOOTSTRAP —

ILIST.lsp BOOTSTRAP

ILIST depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ILIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **ILIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ILIST.lsp BOOTSTRAP —

INT.lsp BOOTSTRAP

INT depends on **OINTDOM** which depends on **ORDRING** which depends on **INT**. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **INT** category which we can write into the **MID** directory. We compile the lisp code and copy the **INT.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

ISTRING.lsp BOOTSTRAP

ISTRING depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **ISTRING** category which we can write into the **MID** directory. We compile the lisp code and copy the **ISTRING.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— ISTRING.lsp BOOTSTRAP —

LIST.lsp BOOTSTRAP

LIST depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **LIST** category which we can write into the **MID** directory. We compile the lisp code and copy the **LIST.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

NNI.lsp BOOTSTRAP

NNI depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **NNI** category which we can write into the **MID** directory. We compile the lisp code and copy the **NNI.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

OUTFORM.lsp BOOTSTRAP

OUTFORM depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **OUTFORM** category which we can write into the **MID** directory. We compile the lisp code and copy the **OUTFORM.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

PI.lsp BOOTSTRAP

PI depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **PI** category which we can write into the **MID** directory. We compile the lisp code and copy the **PI.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

— PI.lsp BOOTSTRAP —

REF.lsp BOOTSTRAP

REF depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **REF** category which we can write into the **MID** directory. We compile the lisp code and copy the **REF.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

SYMBOL.lsp BOOTSTRAP

SYMBOL depends on a chain of files. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **SYMBOL** category which we can write into the **MID** directory. We compile the lisp code and copy the **SYMBOL.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

VECTOR.lsp BOOTSTRAP

VECTOR depends on itself. We need to break this cycle to build the algebra. So we keep a cached copy of the translated **VECTOR** category which we can write into the **MID** directory. We compile the lisp code and copy the **VECTOR.o** file to the **OUT** directory. This is eventually forcibly replaced by a recompiled version.

Note that this code is not included in the generated catdef.spad file.

- [Abra01] Sergei Abramov and Manuel Bronstein. On solutions of linear functional systems, 2001.

Abstract: We describe a new direct algorithm for transforming a linear system of recurrences into an equivalent one with nonsingular leading or trailing matrix. Our algorithm, which is an improvement to the EG elimination method, uses only elementary linear algebra operations (ranks, kernels, and determinants) to produce an equation satisfied by the degrees of the solutions with finite support. As a consequence, we can bound and compute the polynomial and rational solutions of very general linear functional systems such as systems of differential or (q) -difference equations.

Abstract: We describe a rational algorithm that computes the full partial fraction expansion of a rational function over the algebraic closure of its field of definition. The algorithm uses only gcd operations

over the initial field but the resulting decomposition is expressed with linear denominators. We give examples from its Axiom and Maple implementations.

Abstract: This paper addresses the definitions in OpenMath of the elementary functions. The original OpenMath definitions, like most other sources, simply cite [2] as the definition. We show that this is not adequate, and propose precise definitions, and explore the relationships between these definitions. In particular, we introduce the concept of a couth pair of definitions, e.g. of arcsin and arcsinh, and show that the pair arccot and *arccoth* can be couth.

- [Cox07] David Cox, John Little, and Donald O’Shea. *Ideals, varieties and algorithms. An introduction to computational algebraic geometry and commutative algebra.* Springer, 2007, 978-0-387-35650-1.

Abstract: Around 1980 two new directions in science and technique came together. One was Buchbergers algorithms in order to handle Groebner bases in an effective way for solving polynomial equations. The second one was the development of the personal computers. This was the starting point of a computational perspective in commutative algebra and algebraic geometry. In 1991 the three authors invented the first edition of their book as an introduction for undergraduates to some interesting ideas in commutative algebra and algebraic geometry with a strong perspective to practical and computational aspects. A second revised edition appeared in 1996. That means from the very beginning the book provides a bridge for the new, computational aspects in the field of commutative algebra and algebraic geometry. To be more precise, the book gives an introduction to Buchbergers algorithm with applications to syzygies, Hilbert polynomials, primary decompositions. There is an introduction to classical algebraic geometry with applications to the ideal membership problem, solving polynomial equations, and elimination theory. Some more spectacular applications are about robotics, automatic geometric theorem proving, and invariants of finite groups. It seems to the reviewer to carry coals to Newcastle for estimating the importance and usefulness of the book. It should be of some interest to ask how many undergraduates have been introduced to algorithmic aspects of commutative algebra and algebraic geometry following the line of the book. The reviewer will be sure that this will continue in the future too. What are the changes to the previous editions? There is a significant shorter proof of the Extension Theorem, see 3.6 in Chapter 3, suggested by A.H.M. Levelt. A major update has been done in Appendix C “Computer Algebra Systems”. This concerns in the main the section about MAPLE. Some minor updated information concern the use of AXIOM, CoCoA, Macaulay2, Magma, Mathematica, and SINGULAR. This reflects about the recent developments in Computer Algebra Systems. It encourages an interested reader to more practical exercises. The authors have made changes on over 200 pages to enhance clarity and correctness. Many individuals have reported typographical errors and gave the authors feedback on the earlier editions. The book is well-written. The reviewer guesses that

it will become more and more difficult to earn 1 dollar (sponsored by the authors) for every new typographical error as it was the case also with the first and second edition. The reviewer is sure that it will be an excellent guide to introduce further undergraduates in the algorithmic aspect of commutative algebra and algebraic geometry.

[Dewa92] Michael C. Dewar. Using computer algebra to select numerical algorithms. In *Proc. ISSAC 1992*, ISSAC 1992, pages 1–8, 1992.

Abstract: Many real-life problems require a combination of both symbolic and numerical methods for their solution. This has led to the development of integrated, interactive symbolic / numeric packages which use a computer algebra system for the former and a standard subroutine library for the latter. These systems may also be viewed as simplified front-ends to the numerical library. To use these packages, however, a user must be able to select which of the many available routines is the most appropriate for his or her problem, which contrasts with the “black-box” style interfaces available in computer algebra systems. This paper describes how a computer algebra system can be used to make this decision, thus providing a much-simplified and more orthogonal interface.

[Dupe95] Brian J. Dupee and James H. Davenport. Using computer algebra to choose and apply numerical routines, 1995.

Abstract: In applied mathematics, electronic and chemical engineering, the modelling process can produce a number of mathematical problems which require numerical solutions for which symbolic methods are either not possible or not obvious. With the plethora of numerical library routines for the solution of these problems often the numerical analyst has to answer the question *Which routine to choose?* and *How do I use it?*. Some analysis needs to be carried out before the appropriate routine can be identified, i.e. *How stiff is this ODE?* and *Is this function continuous?*. It may well be the case that more than one routine is applicable to the problem. So the question may become *Which is likely to be the best?*. Such a choice may be critical for both accuracy and efficiency. An expert system is thus required to make this choice based on the results of its own analysis of the problem, call the routine and act on the outcome. This may be to put the answer in a relevant form or react to an apparent failure of the chosen routine and thus choose and call an alternative. It should also have sufficient explanation mechanisms to inform on the choice of routine and the reasons for that choice. Much of this work can be achieved using computer algebra and symbolic algebra packages. This paper describes an expert system currently in prototype in terms of both its object-based structure and its computational agents. Some of these agents are described in detail, paying particular attention to the practical aspects of their algorithms and the use of computer algebra. The **axiom2** Symbolic Algebra System is used as a user interface as well as the link to the NAG Foundation Library for the numerical routines and the inference mechanisms for the expert system.

- [Emir04] Ioannis Z. Emiris and Elias P. Tsigaridas. Comparing real algebraic numbers of small degree. In *12th annual European symposium*, ESA 2004, pages 652–663, 2004, 3-540-23025-4.

Abstract: We study polynomials of degree up to 4 over the rationals or a computable real subfield. Our motivation comes from the need to evaluate predicates in nonlinear computational geometry efficiently and exactly. We show a new method to compare real algebraic numbers by precomputing generalized Sturm sequences, thus avoiding iterative methods; the method, moreover handles all degenerate cases. Our first contribution is the determination of rational isolating points, as functions of the coefficients, between any pair of real roots. Our second contribution is to exploit invariants and Bezoutian subexpressions in writing the sequences, in order to reduce bit complexity. The degree

of the tested quantities in the input coefficients is optimal for degree up to 3, and for degree 4 in certain cases. Our methods readily apply to real solving of pairs of quadratic equations, and to sign determination of polynomials over algebraic numbers of degree up to 4. Our third contribution is an implementation in a new module of library SYNAPS v2.1. It improves significantly upon the efficiency of certain publicly available implementations: Rioboos approach on AXIOM, the package of Guibas-Karavelas-Russel, and CORE v1.6, MAPLE v9, and SYNAPS v2.0. Some existing limited tests had shown that it is faster than commercial library LEDA v4.5 for quadratic algebraic numbers.

- [Fate01a] Richard J. Fateman. A critique of openmath and thoughts on encoding mathematics, 2001.

Abstract: The OpenMath project, as portrayed in the Special Issue of the SIGSAM Bulletin (volume 34 no. 2), seems to have a number of problems to face. One of them is the (apparently implicit) assumption that OpenMath designers, through dint of mathematical thought and the advice of the members of the Open Math Society, have solved, in their domain, one of the most pressing problems of software engineering today, namely software re-use. After six years there is insufficient evidence on which to base any claims of success and it appears that most substantive practical issues of mathematical representation and communication have yet to be addressed. We also raise questions about related computational mathematical goals and mathematical encodings.

Abstract: Finite fields play an important role for many applications (e.g. coding theory, cryptography). There are different ways to construct a finite field for a given prime power. The paper describes the different constructions implemented in AXIOM. These are *polynomial basis representation*, *cyclic group representation*, and *normal basis representation*. Furthermore, the concept of the implementation, the used algorithms and the various datatype coercions between these representations are discussed.

[Hawk95] Evatt Hawkes and Grant Keady. Two more links to nag numerics involving ca systems. In *IMACS Applied Computer Algebra Conference*, 1995.

Abstract: The 'more' in the title is because this paper is a sequel to papers by Keving Broughan, [BKRRD,BK]. For some years GK has had interests in (i) interactive front-ends to numeric computation, such as the NAG/IMSL library computation, and (ii) Fortran code generation for Argument SubPrograms (ASPs), such as those needed by some NAG/IMSL routines. Demonstrations of three links to the NAG library are described in [BKRRD]. A description of a link to NAG from Macsyma which was mentioned, but not in a sufficiently advanced state to demonstrate in early 1991, is given in [BK]. The situation at the end of 1991 was that there were links to NAG involving each of Macsyma, REDUCE and Mathematica. The links are called Naglink, IRENA and InterCall, respectively. The principal authors of IRENA are Mike Dewar and Mike Richardson. InterCall is not specific to the NAG library; indeed InterCall is used with calls to IMSL and to elsewhere at the conference venue, the University of New Mexico. The two further links to NAG library treated in this paper are AXIOM2.0 and genmex/ESC, genmex allows calls to NAG from Matlab. genmex can be regarded as similar to InterCall: genmex uses Matlab's mex files in a similar way to InterCall's use of Mathematica's MathLink. Again genmex is not specific to the NAG library. Mike Dewar is an author both of IRENA and the AXIOM2.0 link to the NAG library: see [D] for discussion of the differences between the IRENA project and the AXIOM-NAG link project.

- [Reed97] Mary Lynn Reed. Algebraic structure of genetic inheritance. *Bulletin of the American Mathematical Society*, 34(2):107–130, April 1997.

Abstract: In this paper we will explore the nonassociative algebraic structure that naturally occurs as genetic information gets passed down through the generations. While modern understanding of genetic inheritance initiated with the theories of Charles Darwin, it was the Augustinian monk Gregor Mendel who began to uncover the mathematical nature of the subject. In fact, the symbolism Mendel used to describe his first results (e.g. see his 1866 paper *Experiments in Plant-Hybridization*) is quite algebraically suggestive. Seventy four years later, I.M.H. Etherington introduced the formal language of abstract algebra to the study of genetics in his series of seminal papers. In this paper we will discuss the concepts of genetics that suggest the underlying algebraic structure of inheritance, and we will give a brief overview of the algebras which arise in genetics and some of their basic properties and relationships. With the popularity of biologically motivated mathematics continuing to rise, we offer this survey article as another example of the breadth of mathematics that has biological significance. The most comprehensive reference for the mathematical research done in this area (through 1980) is Worz-Busekros.

Abstract: Real algebraic numbers appear in many Computer Algebra problems. For instance the determination of a cylindrical algebraic decomposition for an euclidean space requires computing with real algebraic numbers. This paper describes an implementation for computations with the real roots of a polynomial. This process is designed to be recursively used, so the resulting domain of computation is the set of all real algebraic numbers. An implementation for the real algebraic closure has been done in Axiom (previously called Scratchpad).
