SYNOPSIS
   Functions/Subroutines
       subroutine dgesvd (JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT,
           WORK, LWORK, INFO)
            DGESVD computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine dgesvd (character JOBU, character JOBVT, integer M, integer N,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) S, double precision, dimension( ldu, * ) U, integer LDU,
       double precision, dimension( ldvt, * ) VT, integer LDVT, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
        DGESVD computes the singular value decomposition (SVD) for GE matrices

Purpose:
   DGESVD computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

   A = U * SIGMA * transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
   V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns V**T, not V.
```

```
Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'A':  all M columns of U are returned in array U:
   = 'S':  the first min(m,n) columns of U (the left singular
           vectors) are returned in the array U;
   = 'O':  the first min(m,n) columns of U (the left singular
           vectors) are overwritten on the array A;
   = 'N':  no columns of U (no left singular vectors) are computed.

 JOBVT
   JOBVT is CHARACTER*1
   Specifies options for computing all or part of the matrix V**T:
   = 'A':  all N rows of V**T are returned in the array VT;
   = 'S':  the first min(m,n) rows of V**T (the right singular
           vectors) are returned in the array VT;
   = 'O':  the first min(m,n) rows of V**T (the right singular
           vectors) are overwritten on the array A;
   = 'N':  no rows of V**T (no right singular vectors) are computed.

   JOBVT and JOBU cannot both be 'O'.

 M
   M is INTEGER
   The number of rows of the input matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the input matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if JOBU = 'O',  A is overwritten with the first min(m,n)
                   columns of U (the left singular vectors,
                   stored columnwise);
   if JOBVT = 'O', A is overwritten with the first min(m,n)
                   rows of V**T (the right singular vectors,
                   stored rowwise);
   if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 S
```

```
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is DOUBLE PRECISION array, dimension (LDU,UCOL)
  (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'.
  If JOBU = 'A', U contains the M-by-M orthogonal matrix U;
  if JOBU = 'S', U contains the first min(m,n) columns of U
  (the left singular vectors, stored columnwise);
  if JOBU = 'N' or 'O', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'S' or 'A', LDU >= M.

VT
  VT is DOUBLE PRECISION array, dimension (LDVT,N)
  If JOBVT = 'A', VT contains the N-by-N orthogonal matrix V**T;
  if JOBVT = 'S', VT contains the first min(m,n) rows of
  V**T (the right singular vectors, stored rowwise);
  if JOBVT = 'N' or 'O', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;
  if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged
  superdiagonal elements of an upper bidiagonal matrix B
  whose diagonal is in S (not necessarily sorted). B
  satisfies A = U * B * VT, so it has the same singular values
  as A, and singular vectors related by U and VT.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= MAX(1,5*MIN(M,N)) for the paths (see comments inside code):
  - PATH 1  (M much larger than N, JOBU='N')
  - PATH 1t (N much larger than M, JOBVT='N')
  LWORK >= MAX(1,3*MIN(M,N)+MAX(M,N),5*MIN(M,N)) for the other paths
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  if DBDSQR did not converge, INFO specifies how many
         superdiagonals of an intermediate bidiagonal form B
         did not converge to zero. See the description of WORK
         above for details.
```

            DGESVDX computes the singular value decomposition (SVD) for GE
```

```
          matrices

Function/Subroutine Documentation
   subroutine dgesvdx (character JOBU, character JOBVT, character RANGE,
       integer M, integer N, double precision, dimension( lda, * ) A, integer
       LDA, double precision VL, double precision VU, integer IL, integer IU,
       integer NS, double precision, dimension( * ) S, double precision,
       dimension( ldu, * ) U, integer LDU, double precision, dimension( ldvt,
       * ) VT, integer LDVT, double precision, dimension( * ) WORK, integer
       LWORK, integer, dimension( * ) IWORK, integer INFO)
        DGESVDX computes the singular value decomposition (SVD) for GE
       matrices

Purpose:
   DGESVDX computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

   A = U * SIGMA * transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
   V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   DGESVDX uses an eigenvalue problem for obtaining the SVD, which
   allows for the computation of a subset of singular values and
   vectors. See DBDSVDX for details.

   Note that the routine returns V**T, not V.

Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'V':  the first min(m,n) columns of U (the left singular
           vectors) or as specified by RANGE are returned in
           the array U;
   = 'N':  no columns of U (no left singular vectors) are computed.

 JOBVT
   JOBVT is CHARACTER*1
   Specifies options for computing all or part of the matrix V**T:
   = 'V':  the first min(m,n) rows of V**T (the right singular
           vectors) or as specified by RANGE are returned in
           the array VT;
   = 'N':  no rows of V**T (no right singular vectors) are computed.
```

```
RANGE
  RANGE is CHARACTER*1
  = 'A': all singular values will be found.
  = 'V': all singular values in the half-open interval (VL,VU]
         will be found.
  = 'I': the IL-th through IU-th singular values will be found.

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

VL
  VL is DOUBLE PRECISION
  VL >=0.

VU
  VU is DOUBLE PRECISION
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for singular values. VU > VL.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest singular values to be returned.
  1 <= IL <= IU <= min(M,N), if min(M,N) > 0.
  Not referenced if RANGE = 'A' or 'V'.

NS
  NS is INTEGER
  The total number of singular values found,
  0 <= NS <= min(M,N).
  If RANGE = 'A', NS = min(M,N); if RANGE = 'I', NS = IU-IL+1.
```

```
S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is DOUBLE PRECISION array, dimension (LDU,UCOL)
  If JOBU = 'V', U contains columns of U (the left singular
  vectors, stored columnwise) as specified by RANGE; if
  JOBU = 'N', U is not referenced.
  Note: The user must ensure that UCOL >= NS; if RANGE = 'V',
  the exact value of NS is not known ILQFin advance and an upper
  bound must be used.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'V', LDU >= M.

VT
  VT is DOUBLE PRECISION array, dimension (LDVT,N)
  If JOBVT = 'V', VT contains the rows of V**T (the right singular
  vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N',
  VT is not referenced.
  Note: The user must ensure that LDVT >= NS; if RANGE = 'V',
  the exact value of NS is not known in advance and an upper
  bound must be used.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'V', LDVT >= NS (see above).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= MAX(1,MIN(M,N)*(MIN(M,N)+4)) for the paths (see
  comments inside the code):
  - PATH 1  (M much larger than N)
  - PATH 1t (N much larger than M)
  LWORK >= MAX(1,MIN(M,N)*2+MAX(M,N)) for the other paths.
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
```

```
  message related to LWORK is issued by XERBLA.

 IWORK
  IWORK is INTEGER array, dimension (12*MIN(M,N))
  If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0,
  then IWORK contains the indices of the eigenvectors that failed
  to converge in DBDSVDX/DSTEVX.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, then i eigenvectors failed to converge
        in DBDSVDX/DSTEVX.
        if INFO = N*2 + 1, an internal error occurred in DBDSVDX

SYNOPSIS
   Functions/Subroutines
       subroutine sgejsv (JOBA, JOBU, JOBV, JOBR, JOBT, JOBP, M, N, A, LDA,
           SVA, U, LDU, V, LDV, WORK, LWORK, IWORK, INFO)
           SGEJSV

Function/Subroutine Documentation
   subroutine sgejsv (character*1 JOBA, character*1 JOBU, character*1 JOBV,
       character*1 JOBR, character*1 JOBT, character*1 JOBP, integer M,
       integer N, real, dimension( lda, * ) A, integer LDA, real, dimension( n
       ) SVA, real, dimension( ldu, * ) U, integer LDU, real, dimension( ldv,
       * ) V, integer LDV, real, dimension( lwork ) WORK, integer LWORK,
       integer, dimension( * ) IWORK, integer INFO)
       SGEJSV

Purpose:
   SGEJSV computes the singular value decomposition (SVD) of a real M-by-N
   matrix [A], where M >= N. The SVD of [A] is written as

   [A] = [U] * [SIGMA] * [V]^t,

   where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N
   diagonal elements, [U] is an M-by-N (or M-by-M) orthonormal matrix, and
   [V] is an N-by-N orthogonal matrix. The diagonal elements of [SIGMA] are
   the singular values of [A]. The columns of [U] and [V] are the left and
   the right singular vectors of [A], respectively. The matrices [U] and [V]
   are computed and stored in the arrays U and V, respectively. The diagonal
   of [SIGMA] is computed and stored in the array SVA.
   SGEJSV can sometimes compute tiny singular values and their singular
   vectors much more accurately than other SVD routines,
   see below under Further Details.

Parameters:

 JOBA
   JOBA is CHARACTER*1
   Specifies the level of accuracy:
   = 'C': This option works well (high relative accuracy) if A = B * D,
          with well-conditioned B and arbitrary diagonal matrix D.
          The accuracy cannot be spoiled by COLUMN scaling. The
          accuracy of the computed output depends on the condition of
          B, and the procedure aims at the best theoretical accuracy.
          The relative error max_{i=1:N}|d sigma_i| / sigma_i is
          bounded by f(M,N)*epsilon* cond(B), independent of D.
          The input matrix is preprocessed with the QRF with column
```

```
          pivoting. This initial preprocessing and preconditioning by
          a rank revealing QR factorization is common for all values of
          JOBA. Additional actions are specified as follows:
  = 'E': Computation as with 'C' with an additional estimate of the
          condition number of B. It provides a realistic error bound.
  = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings
          D1, D2, and well-conditioned matrix C, this option gives
          higher accuracy than the 'C' option. If the structure of the
          input matrix is not known, and relative accuracy is
          desirable, then this option is advisable. The input matrix A
          is preprocessed with QR factorization with FULL (row and
          column) pivoting.
  = 'G'  Computation as with 'F' with an additional estimate of the
          condition number of B, where A=D*B. If A has heavily weighted
          rows, then using this condition number gives too pessimistic
          error bound.
  = 'A': Small singular values are the noise and the matrix is treated
          as numerically rank defficient. The error in the computed
          singular values is bounded by f(m,n)*epsilon*||A||.
          The computed SVD A = U * S * V^t restores A up to
          f(m,n)*epsilon*||A||.
          This gives the procedure the licence to discard (set to zero)
          all singular values below N*epsilon*||A||.
  = 'R': Similar as in 'A'. Rank revealing property of the initial
          QR factorization is used do reveal (using triangular factor)
          a gap sigma_{r+1} < epsilon * sigma_r in which case the
          numerical RANK is declared to be r. The SVD is computed with
          absolute error bounds, but more accurately than with 'A'.

JOBU
  JOBU is CHARACTER*1
  Specifies whether to compute the columns of U:
  = 'U': N columns of U are returned in the array U.
  = 'F': full set of M left sing. vectors is returned in the array U.
  = 'W': U may be used as workspace of length M*N. See the description of U.
  = 'N': U is not computed.

JOBV
  JOBV is CHARACTER*1
  Specifies whether to compute the matrix V:
  = 'V': N columns of V are returned in the array V; Jacobi rotations
          are not explicitly accumulated.
  = 'J': N columns of V are returned in the array V, but they are
          computed as the product of Jacobi rotations. This option is
          allowed only if JOBU .NE. 'N', i.e. in computing the full SVD.
  = 'W': V may be used as workspace of length N*N. See the description of V.
  = 'N': V is not computed.

JOBR
  JOBR is CHARACTER*1
```

```
  Specifies the RANGE for the singular values. Issues the licence to
  set to zero small positive singular values if they are outside
  specified range. If A .NE. 0 is scaled so that the largest singular
  value of c*A is around SQRT(BIG), BIG=SLAMCH('O'), then JOBR issues
  the licence to kill columns of A whose norm in c*A is less than
  SQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN,
  where SFMIN=SLAMCH('S'), EPSLN=SLAMCH('E').
  = 'N': Do not kill small columns of c*A. This option assumes that
         BLAS and QR factorizations and triangular solvers are
         implemented to work in that range. If the condition of A
         is greater than BIG, use SGESVJ.
  = 'R': RESTRICTED range for sigma(c*A) is [SQRT(SFMIN), SQRT(BIG)]
         (roughly, as described above). This option is recommended.
                           ===========================
  For computing the singular values in the FULL range [SFMIN,BIG]
  use SGESVJ.

JOBT
  JOBT is CHARACTER*1
  If the matrix is square then the procedure may determine to use
  transposed A if A^t seems to be better with respect to convergence.
  If the matrix is not square, JOBT is ignored. This is subject to
  changes in the future.
  The decision is based on two values of entropy over the adjoint
  orbit of A^t * A. See the descriptions of WORK(6) and WORK(7).
  = 'T': transpose if entropy test indicates possibly faster
         convergence of Jacobi process if A^t is taken as input. If A is
         replaced with A^t, then the row pivoting is included automatically.
  = 'N': do not speculate.
  This option can be used to compute only the singular values, or the
  full SVD (U, SIGMA and V). For only one set of singular vectors
  (U or V), the caller should provide both U and V, as one of the
  matrices is used as workspace if the matrix A is transposed.
  The implementer can easily remove this constraint and make the
  code more complicated. See the descriptions of U and V.

JOBP
  JOBP is CHARACTER*1
  Issues the licence to introduce structured perturbations to drown
  denormalized numbers. This licence should be active if the
  denormals are poorly implemented, causing slow computation,
  especially in cases of fast convergence (!). For details see [1,2].
  For the sake of simplicity, this perturbations are included only
  when the full SVD or only the singular values are requested. The
  implementer/user can easily add the perturbation for the cases of
  computing one set of singular vectors.
  = 'P': introduce perturbation
  = 'N': do not perturb

M
```

```
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A. M >= N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the M-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is REAL array, dimension (N)
  On exit,
  - For WORK(1)/WORK(2) = ONE: The singular values of A. During the
    computation SVA contains Euclidean column norms of the
    iterated matrices in the array A.
  - For WORK(1) .NE. WORK(2): The singular values of A are
    (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if
    sigma_max(A) overflows or if small singular values have been
    saved from underflow by scaling the input matrix A.
  - If JOBR='R' then some of the singular values may be returned
    as exact zeros obtained by "set to zero" because they are
    below the numerical rank threshold or are denormalized numbers.

U
  U is REAL array, dimension ( LDU, N )
  If JOBU = 'U', then U contains on exit the M-by-N matrix of
       the left singular vectors.
  If JOBU = 'F', then U contains on exit the M-by-M matrix of
       the left singular vectors, including an ONB
       of the orthogonal complement of the Range(A).
  If JOBU = 'W'  .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N),
       then U is used as workspace if the procedure
       replaces A with A^t. In that case, [V] is computed
       in U as left singular vectors of A^t and then
       copied back to the V array. This 'W' option is just
       a reminder to the caller that in this case U is
       reserved as workspace of length N*N.
  If JOBU = 'N'  U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U,  LDU >= 1.
  IF  JOBU = 'U' or 'F' or 'W',  then LDU >= M.
```

```
V
  V is REAL array, dimension ( LDV, N )
  If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of
       the right singular vectors;
  If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N),
       then V is used as workspace if the pprocedure
       replaces A with A^t. In that case, [U] is computed
       in V as right singular vectors of A^t and then
       copied back to the U array. This 'W' option is just
       a reminder to the caller that in this case V is
       reserved as workspace of length N*N.
  If JOBV = 'N'  V is not referenced.

LDV
  LDV is INTEGER
  The leading dimension of the array V,  LDV >= 1.
  If JOBV = 'V' or 'J' or 'W', then LDV >= N.

WORK
  WORK is REAL array, dimension at least LWORK.
  On exit,
  WORK(1) = SCALE = WORK(2) / WORK(1) is the scaling factor such
      that SCALE*SVA(1:N) are the computed singular values
      of A. (See the description of SVA().)
  WORK(2) = See the description of WORK(1).
  WORK(3) = SCONDA is an estimate for the condition number of
      column equilibrated A. (If JOBA .EQ. 'E' or 'G')
      SCONDA is an estimate of SQRT(||(R^t * R)^(-1)||_1).
      It is computed using SPOCON. It holds
      N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA
      where R is the triangular factor from the QRF of A.
      However, if R is truncated and the numerical rank is
      determined to be strictly smaller than N, SCONDA is
      returned as -1, thus indicating that the smallest
      singular values might be lost.

  If full SVD is needed, the following two condition numbers are
  useful for the analysis of the algorithm. They are provied for
  a developer/implementer who is familiar with the details of
  the method.

  WORK(4) = an estimate of the scaled condition number of the
      triangular factor in the first QR factorization.
  WORK(5) = an estimate of the scaled condition number of the
      triangular factor in the second QR factorization.

  The following two parameters are computed if JOBT .EQ. 'T'.
  They are provided for a developer/implementer who is familiar
  with the details of the method.
```

```
  WORK(6) = the entropy of A^t*A :: this is the Shannon entropy
      of diag(A^t*A) / Trace(A^t*A) taken as point in the
      probability simplex.
  WORK(7) = the entropy of A*A^t.

LWORK
  LWORK is INTEGER
  Length of WORK to confirm proper allocation of work space.
  LWORK depends on the job:

  If only SIGMA is needed ( JOBU.EQ.'N', JOBV.EQ.'N' ) and
  -> .. no scaled condition estimate required (JOBE.EQ.'N'):
        LWORK >= max(2*M+N,4*N+1,7). This is the minimal requirement.
    ->> For optimal performance (blocked code) the optimal value
        is LWORK >= max(2*M+N,3*N+(N+1)*NB,7). Here NB is the optimal
        block size for DGEQP3 and DGEQRF.
        In general, optimal LWORK is computed as
        LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF), 7).
  -> .. an estimate of the scaled condition number of A is
        required (JOBA='E', 'G'). In this case, LWORK is the maximum
        of the above and N*N+4*N, i.e. LWORK >= max(2*M+N,N*N+4*N,7).
    ->> For optimal performance (blocked code) the optimal value
        is LWORK >= max(2*M+N,3*N+(N+1)*NB, N*N+4*N, 7).
        In general, the optimal length LWORK is computed as
         LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DGEQRF),
                  N+N*N+LWORK(DPOCON),7).

  If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'),
  -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7).
  -> For optimal performance, LWORK >= max(2*M+N,3*N+(N+1)*NB,7),
     where NB is the optimal block size for DGEQP3, DGEQRF, DGELQ,
     DORMLQ. In general, the optimal length LWORK is computed as
     LWORK >= max(2*M+N,N+LWORK(DGEQP3), N+LWORK(DPOCON),
              N+LWORK(DGELQ), 2*N+LWORK(DGEQRF), N+LWORK(DORMLQ)).

  If SIGMA and the left singular vectors are needed
  -> the minimal requirement is LWORK >= max(2*M+N,4*N+1,7).
  -> For optimal performance:
     if JOBU.EQ.'U' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,7),
     if JOBU.EQ.'F' :: LWORK >= max(2*M+N,3*N+(N+1)*NB,N+M*NB,7),
         where NB is the optimal block size for DGEQP3, DGEQRF, DORMQR.
         In general, the optimal length LWORK is computed as
         LWORK >= max(2*M+N,N+LWORK(DGEQP3),N+LWORK(DPOCON),
                  2*N+LWORK(DGEQRF), N+LWORK(DORMQR)).
         Here LWORK(DORMQR) equals N*NB (for JOBU.EQ.'U') or
                  M*NB (for JOBU.EQ.'F').

  If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and
  -> if JOBV.EQ.'V' the minimal requirement is
        LWORK >= max(2*M+N,6*N+2*N*N).
```

```
   -> if JOBV.EQ.'J' the minimal requirement is
         LWORK >= max(2*M+N, 4*N+N*N,2*N+N*N+6).
   -> For optimal performance, LWORK should be additionally
   larger than N+M*NB, where NB is the optimal block size for DORMQR.

 IWORK
   IWORK is INTEGER array, dimension M+3*N.
   On exit,
   IWORK(1) = the numerical rank determined after the initial
        QR factorization with pivoting. See the descriptions
        of JOBA and JOBR.
   IWORK(2) = the number of the computed nonzero singular values
   IWORK(3) = if nonzero, a warning message:
        If IWORK(3).EQ.1 then some of the column norms of A
        were denormalized floats. The requested high accuracy
        is not warranted by the data.

 INFO
   INFO is INTEGER
   < 0  : if INFO = -i, then the i-th argument had an illegal value.
   = 0 :  successfull exit;
   > 0 :  SGEJSV  did not converge in the maximal allowed number
          of sweeps. The computed values may be inaccurate.

Further Details:
   SGEJSV implements a preconditioned Jacobi SVD algorithm. It uses SGEQP3,
   SGEQRF, and SGELQF as preprocessors and preconditioners. Optionally, an
   additional row pivoting can be used as a preprocessor, which in some
   cases results in much higher accuracy. An example is matrix A with the
   structure A = D1 * C * D2, where D1, D2 are arbitrarily ill-conditioned
   diagonal matrices and C is well-conditioned matrix. In that case, complete
   pivoting in the first QR factorizations provides accuracy dependent on the
   condition number of C, and independent of D1, D2. Such higher accuracy is
   not completely understood theoretically, but it works well in practice.
   Further, if A can be written as A = B*D, with well-conditioned B and some
   diagonal D, then the high accuracy is guaranteed, both theoretically and
   in software, independent of D. For more details see [1], [2].
   The computational range for the singular values can be the full range
   ( UNDERFLOW,OVERFLOW ), provided that the machine arithmetic and the BLAS
   & LAPACK routines called by SGEJSV are implemented to work in that range.
   If that is not the case, then the restriction for safe computation with
   the singular values in the range of normalized IEEE numbers is that the
   spectral condition number kappa(A)=sigma_max(A)/sigma_min(A) does not
   overflow. This code (SGEJSV) is best used in this restricted range,
   meaning that singular values of magnitude below ||A||_2 / SLAMCH('O') are
   returned as zeros. See JOBR for details on this.
   Further, this implementation is somewhat slower than the one described
   in [1,2] due to replacement of some non-LAPACK components, and because
   the choice of some tuning parameters in the iterative part (SGESVJ) is
   left to the implementer on a particular machine.
```

```
The rank revealing QR factorization (in this code: SGEQP3) should be
implemented as in [3]. We have a new version of SGEQP3 under development
that is more robust than the current one in LAPACK, with a cleaner cut in
rank defficient cases. It will be available in the SIGMA library [4].
If M is much larger than N, it is obvious that the inital QRF with
column pivoting can be preprocessed by the QRF without pivoting. That
well known trick is not used in SGEJSV because in some cases heavy row
weighting can be treated with complete pivoting. The overhead in cases
M much larger than N is then only due to pivoting, but the benefits in
terms of accuracy have prevailed. The implementer/user can incorporate
this extra QRF step easily. The implementer can also improve data movement
(matrix transpose, matrix copy, matrix transposed copy) - this
implementation of SGEJSV uses only the simplest, naive data movement.
```

*
*     Preconditioning
*
*     If the full SVD is needed, the right singular vectors are computed
*     from a matrix equation, and for that we need theoretical analysis
*     of the Businger-Golub pivoting. So we use SGEQP3 as the first RR QRF.
*     In all other cases the first RR QRF can be chosen by other criteria
*     (eg speed by replacing global with restricted window pivoting, such
*     as in SGEQPX from TOMS # 782). Good results will be obtained using
*     SGEQPX with properly (!) chosen numerical parameters.
*     Any improvement of SGEQP3 improves overal performance of SGEJSV.
*

SYNOPSIS
   Functions/Subroutines
       subroutine sgesdd (JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,
           LWORK, IWORK, INFO)
           SGESDD

Function/Subroutine Documentation
   subroutine sgesdd (character JOBZ, integer M, integer N, real, dimension(
       lda, * ) A, integer LDA, real, dimension( * ) S, real, dimension( ldu,
       * ) U, integer LDU, real, dimension( ldvt, * ) VT, integer LDVT, real,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer INFO)
       SGESDD

Purpose:
   SGESDD computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, optionally computing the left and right singular
   vectors.  If singular vectors are desired, it uses a
   divide-and-conquer algorithm.

   The SVD is written

   A = U * SIGMA * transpose(V)
```

```
   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
   V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns VT = V**T, not V.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'A':  all M columns of U and all N rows of V**T are
           returned in the arrays U and VT;
   = 'S':  the first min(M,N) columns of U and the first
           min(M,N) rows of V**T are returned in the arrays U and VT;
   = 'O':  If M >= N, the first N columns of U are overwritten
           on the array A and all rows of V**T are returned in the array VT;
           otherwise, all columns of U are returned in the
           array U and the first M rows of V**T are overwritten
           in the array A;
   = 'N':  no columns of U or rows of V**T are computed.

 M
   M is INTEGER
   The number of rows of the input matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the input matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if JOBZ = 'O',  A is overwritten with the first N columns
        of U (the left singular vectors, stored columnwise) if M >= N;
        A is overwritten with the first M rows
        of V**T (the right singular vectors, stored rowwise) otherwise.
   if JOBZ .ne. 'O', the contents of A are destroyed.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is REAL array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is REAL array, dimension (LDU,UCOL)
  UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N;
  UCOL = min(M,N) if JOBZ = 'S'.
  If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M
       orthogonal matrix U;
  if JOBZ = 'S', U contains the first min(M,N) columns of U
       (the left singular vectors, stored columnwise);
  if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT
  VT is REAL array, dimension (LDVT,N)
  If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the
  N-by-N orthogonal matrix V**T;
  if JOBZ = 'S', VT contains the first min(M,N) rows of
  V**T (the right singular vectors, stored rowwise);
  if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N;
  if JOBZ = 'S', LDVT >= min(M,N).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 1.
  If JOBZ = 'N', LWORK >= 3*min(M,N) + max(max(M,N),6*min(M,N)).
  If JOBZ = 'O', LWORK >= 3*min(M,N) +
                         max(max(M,N),5*min(M,N)*min(M,N)+4*min(M,N)).
  If JOBZ = 'S' or 'A' LWORK >= min(M,N)*(7+4*min(M,N))
  For good performance, LWORK should generally be larger.
  If LWORK = -1 but other input arguments are legal, WORK(1)
```

```
  returns the optimal LWORK.

 IWORK
  IWORK is INTEGER array, dimension (8*min(M,N))

 INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  SBDSDC did not converge, updating process failed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgesvd (JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT,
           WORK, LWORK, INFO)
            SGESVD computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine sgesvd (character JOBU, character JOBVT, integer M, integer N,
       real, dimension( lda, * ) A, integer LDA, real, dimension( * ) S, real,
       dimension( ldu, * ) U, integer LDU, real, dimension( ldvt, * ) VT,
       integer LDVT, real, dimension( * ) WORK, integer LWORK, integer INFO)
        SGESVD computes the singular value decomposition (SVD) for GE matrices

Purpose:
   SGESVD computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

   A = U * SIGMA * transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
   V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns V**T, not V.

Parameters:
```

```
JOBU
  JOBU is CHARACTER*1
  Specifies options for computing all or part of the matrix U:
  = 'A':  all M columns of U are returned in array U:
  = 'S':  the first min(m,n) columns of U (the left singular
          vectors) are returned in the array U;
  = 'O':  the first min(m,n) columns of U (the left singular
          vectors) are overwritten on the array A;
  = 'N':  no columns of U (no left singular vectors) are computed.

JOBVT
  JOBVT is CHARACTER*1
  Specifies options for computing all or part of the matrix
  V**T:
  = 'A':  all N rows of V**T are returned in the array VT;
  = 'S':  the first min(m,n) rows of V**T (the right singular
          vectors) are returned in the array VT;
  = 'O':  the first min(m,n) rows of V**T (the right singular
          vectors) are overwritten on the array A;
  = 'N':  no rows of V**T (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if JOBU = 'O',  A is overwritten with the first min(m,n)
       columns of U (the left singular vectors, stored columnwise);
  if JOBVT = 'O', A is overwritten with the first min(m,n)
       rows of V**T (the right singular vectors, stored rowwise);
  if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is REAL array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
```

```
  U is REAL array, dimension (LDU,UCOL)
  (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'.
  If JOBU = 'A', U contains the M-by-M orthogonal matrix U;
  if JOBU = 'S', U contains the first min(m,n) columns of U
     (the left singular vectors, stored columnwise);
  if JOBU = 'N' or 'O', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'S' or 'A', LDU >= M.

VT
  VT is REAL array, dimension (LDVT,N)
  If JOBVT = 'A', VT contains the N-by-N orthogonal matrix V**T;
  if JOBVT = 'S', VT contains the first min(m,n) rows of
     V**T (the right singular vectors, stored rowwise);
  if JOBVT = 'N' or 'O', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;
  if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged
  superdiagonal elements of an upper bidiagonal matrix B
  whose diagonal is in S (not necessarily sorted). B
  satisfies A = U * B * VT, so it has the same singular values
  as A, and singular vectors related by U and VT.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= MAX(1,5*MIN(M,N)) for the paths (see comments inside code):
  - PATH 1  (M much larger than N, JOBU='N')
  - PATH 1t (N much larger than M, JOBVT='N')
  LWORK >= MAX(1,3*MIN(M,N)+MAX(M,N),5*MIN(M,N)) for the other paths
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit.
```

```
< 0:  if INFO = -i, the i-th argument had an illegal value.
> 0:  if SBDSQR did not converge, INFO specifies how many
      superdiagonals of an intermediate bidiagonal form B
      did not converge to zero. See the description of WORK
      above for details.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgesvdx (JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU,
           NS, S, U, LDU, VT, LDVT, WORK, LWORK, IWORK, INFO)
            SGESVDX computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine sgesvdx (character JOBU, character JOBVT, character RANGE,
       integer M, integer N, real, dimension( lda, * ) A, integer LDA, real
       VL, real VU, integer IL, integer IU, integer NS, real, dimension( * )
       S, real, dimension( ldu, * ) U, integer LDU, real, dimension( ldvt, * )
       VT, integer LDVT, real, dimension( * ) WORK, integer LWORK, integer,
       dimension( * ) IWORK, integer INFO)
        SGESVDX computes the singular value decomposition (SVD) for GE
       matrices

Purpose:
   SGESVDX computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

   A = U * SIGMA * transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
   V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   SGESVDX uses an eigenvalue problem for obtaining the SVD, which
   allows for the computation of a subset of singular values and
   vectors. See SBDSVDX for details.

   Note that the routine returns V**T, not V.
```

```
Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'V':  the first min(m,n) columns of U (the left singular
           vectors) or as specified by RANGE are returned in the array U;
   = 'N':  no columns of U (no left singular vectors) are computed.

 JOBVT
   JOBVT is CHARACTER*1
   Specifies options for computing all or part of the matrix
   V**T:
   = 'V':  the first min(m,n) rows of V**T (the right singular
           vectors) or as specified by RANGE are returned in the array VT;
   = 'N':  no rows of V**T (no right singular vectors) are computed.

 RANGE
   RANGE is CHARACTER*1
   = 'A': all singular values will be found.
   = 'V': all singular values in the half-open interval (VL,VU] will be found.
   = 'I': the IL-th through IU-th singular values will be found.

 M
   M is INTEGER
   The number of rows of the input matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the input matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the contents of A are destroyed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 VL
   VL is REAL
   VL >=0.

 VU
   VU is REAL
   If RANGE='V', the lower and upper bounds of the interval to
   be searched for singular values. VU > VL.
   Not referenced if RANGE = 'A' or 'I'.
```

```
IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest singular values to be returned.
  1 <= IL <= IU <= min(M,N), if min(M,N) > 0.
  Not referenced if RANGE = 'A' or 'V'.

NS
  NS is INTEGER
  The total number of singular values found,
  0 <= NS <= min(M,N).
  If RANGE = 'A', NS = min(M,N); if RANGE = 'I', NS = IU-IL+1.

S
  S is REAL array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is REAL array, dimension (LDU,UCOL)
  If JOBU = 'V', U contains columns of U (the left singular
  vectors, stored columnwise) as specified by RANGE; if
  JOBU = 'N', U is not referenced.
  Note: The user must ensure that UCOL >= NS; if RANGE = 'V',
  the exact value of NS is not known ILQFin advance and an upper
  bound must be used.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'V', LDU >= M.

VT
  VT is REAL array, dimension (LDVT,N)
  If JOBVT = 'V', VT contains the rows of V**T (the right singular
  vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N',
  VT is not referenced.
  Note: The user must ensure that LDVT >= NS; if RANGE = 'V',
  the exact value of NS is not known in advance and an upper
  bound must be used.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'V', LDVT >= NS (see above).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
```

```
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= MAX(1,MIN(M,N)*(MIN(M,N)+4)) for the paths (see
  comments inside the code):
  - PATH 1  (M much larger than N)
  - PATH 1t (N much larger than M)
  LWORK >= MAX(1,MIN(M,N)*2+MAX(M,N)) for the other paths.
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (12*MIN(M,N))
  If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0,
  then IWORK contains the indices of the eigenvectors that failed
  to converge in SBDSVDX/SSTEVX.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, then i eigenvectors failed to converge
        in SBDSVDX/SSTEVX.
  if INFO = N*2 + 1, an internal error occurred in SBDSVDX
```

       integer, dimension( * ) IWORK, integer INFO)
       CGEJSV

Purpose:
   CGEJSV computes the singular value decomposition (SVD) of a real M-by-N
   matrix [A], where M >= N. The SVD of [A] is written as

      [A] = [U] * [SIGMA] * [V]^*,

   where [SIGMA] is an N-by-N (M-by-N) matrix which is zero except for its N
   diagonal elements, [U] is an M-by-N (or M-by-M) orthonormal matrix, and
   [V] is an N-by-N orthogonal matrix. The diagonal elements of [SIGMA] are
   the singular values of [A]. The columns of [U] and [V] are the left and
   the right singular vectors of [A], respectively. The matrices [U] and [V]
   are computed and stored in the arrays U and V, respectively. The diagonal
   of [SIGMA] is computed and stored in the array SVA.

   Arguments:
   ==========

 JOBA
   JOBA is CHARACTER*1
   Specifies the level of accuracy:
   = 'C': This option works well (high relative accuracy) if A = B * D,
          with well-conditioned B and arbitrary diagonal matrix D.
          The accuracy cannot be spoiled by COLUMN scaling. The
          accuracy of the computed output depends on the condition of
          B, and the procedure aims at the best theoretical accuracy.
          The relative error max_{i=1:N}|d sigma_i| / sigma_i is
          bounded by f(M,N)*epsilon* cond(B), independent of D.
          The input matrix is preprocessed with the QRF with column
          pivoting. This initial preprocessing and preconditioning by
```

```
          a rank revealing QR factorization is common for all values of
          JOBA. Additional actions are specified as follows:

   = 'E': Computation as with 'C' with an additional estimate of the
          condition number of B. It provides a realistic error bound.

   = 'F':
     If A = D1 * C * D2 with ill-conditioned diagonal scalings
            D1, D2, and well-conditioned matrix C, this option gives
            higher accuracy than the 'C' option. If the structure of the
            input matrix is not known, and relative accuracy is
            desirable, then this option is advisable. The input matrix A
            is preprocessed with QR factorization with FULL (row and
            column) pivoting.
          = 'G'  Computation as with 'F' with an additional estimate of the
            condition number of B, where A=D*B. If A has heavily weighted
            rows, then using this condition number gives too pessimistic
            error bound.
          = 'A': Small singular values are the noise and the matrix is treated
             as numerically rank defficient. The error in the computed
             singular values is bounded by f(m,n)*epsilon*||A||.
             The computed SVD A = U * S * V^* restores A up to
             f(m,n)*epsilon*||A||.
             This gives the procedure the licence to discard (set to zero)
             all singular values below N*epsilon*||A||.
           = 'R': Similar as in 'A'. Rank revealing property of the initial
             QR factorization is used do reveal (using triangular factor)
             a gap sigma_{r+1} < epsilon * sigma_r in which case the
             numerical RANK is declared to be r. The SVD is computed with
             absolute error bounds, but more accurately than with 'A'.

Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies whether to compute the columns of U:
   = 'U': N columns of U are returned in the array U.
   = 'F': full set of M left sing. vectors is returned in the array U.
   = 'W': U may be used as workspace of length M*N. See the description of U.
   = 'N': U is not computed.

 JOBV
   JOBV is CHARACTER*1
   Specifies whether to compute the matrix V:
   = 'V': N columns of V are returned in the array V; Jacobi rotations
          are not explicitly accumulated.
   = 'J': N columns of V are returned in the array V, but they are
          computed as the product of Jacobi rotations. This option is
          allowed only if JOBU .NE. 'N', i.e. in computing the full SVD.
   = 'W': V may be used as workspace of length N*N. See the description of V.
```

```
  = 'N': V is not computed.

JOBR
  JOBR is CHARACTER*1
  Specifies the RANGE for the singular values. Issues the licence to
  set to zero small positive singular values if they are outside
  specified range. If A .NE. 0 is scaled so that the largest singular
  value of c*A is around SQRT(BIG), BIG=SLAMCH('O'), then JOBR issues
  the licence to kill columns of A whose norm in c*A is less than
  SQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN,
  where SFMIN=SLAMCH('S'), EPSLN=SLAMCH('E').
  = 'N': Do not kill small columns of c*A. This option assumes that
         BLAS and QR factorizations and triangular solvers are
         implemented to work in that range. If the condition of A
         is greater than BIG, use CGESVJ.
  = 'R': RESTRICTED range for sigma(c*A) is [SQRT(SFMIN), SQRT(BIG)]
         (roughly, as described above). This option is recommended.

                         ===========================
  For computing the singular values in the FULL range [SFMIN,BIG]
  use CGESVJ.

JOBT
  JOBT is CHARACTER*1
  If the matrix is square then the procedure may determine to use
  transposed A if A^* seems to be better with respect to convergence.
  If the matrix is not square, JOBT is ignored. This is subject to
  changes in the future.
  The decision is based on two values of entropy over the adjoint
  orbit of A^* * A. See the descriptions of WORK(6) and WORK(7).
  = 'T': transpose if entropy test indicates possibly faster
  convergence of Jacobi process if A^* is taken as input. If A is
  replaced with A^*, then the row pivoting is included automatically.
  = 'N': do not speculate.
         This option can be used to compute only the singular values, or the
         full SVD (U, SIGMA and V). For only one set of singular vectors
         (U or V), the caller should provide both U and V, as one of the
         matrices is used as workspace if the matrix A is transposed.
         The implementer can easily remove this constraint and make the
         code more complicated. See the descriptions of U and V.

JOBP
  JOBP is CHARACTER*1
  Issues the licence to introduce structured perturbations to drown
  denormalized numbers. This licence should be active if the
  denormals are poorly implemented, causing slow computation,
  especially in cases of fast convergence (!). For details see [1,2].
  For the sake of simplicity, this perturbations are included only
  when the full SVD or only the singular values are requested. The
  implementer/user can easily add the perturbation for the cases of
```

```
  computing one set of singular vectors.
  = 'P': introduce perturbation
  = 'N': do not perturb

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A. M >= N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is REAL array, dimension (N)
  On exit,
  - For WORK(1)/WORK(2) = ONE: The singular values of A. During the
    computation SVA contains Euclidean column norms of the
    iterated matrices in the array A.
  - For WORK(1) .NE. WORK(2): The singular values of A are
    (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if
    sigma_max(A) overflows or if small singular values have been
    saved from underflow by scaling the input matrix A.
  - If JOBR='R' then some of the singular values may be returned
    as exact zeros obtained by "set to zero" because they are
    below the numerical rank threshold or are denormalized numbers.

U
  U is COMPLEX array, dimension ( LDU, N )
  If JOBU = 'U', then U contains on exit the M-by-N matrix of
       the left singular vectors.
  If JOBU = 'F', then U contains on exit the M-by-M matrix of
       the left singular vectors, including an ONB
       of the orthogonal complement of the Range(A).
  If JOBU = 'W'  .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N),
       then U is used as workspace if the procedure
       replaces A with A^*. In that case, [V] is computed
       in U as left singular vectors of A^* and then
       copied back to the V array. This 'W' option is just
       a reminder to the caller that in this case U is
       reserved as workspace of length N*N.
  If JOBU = 'N'  U is not referenced.
```

```
LDU
  LDU is INTEGER
  The leading dimension of the array U,  LDU >= 1.
  IF  JOBU = 'U' or 'F' or 'W',  then LDU >= M.

V
  V is COMPLEX array, dimension ( LDV, N )
  If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of
        the right singular vectors;
  If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N),
        then V is used as workspace if the pprocedure
        replaces A with A^*. In that case, [U] is computed
        in V as right singular vectors of A^* and then
        copied back to the U array. This 'W' option is just
        a reminder to the caller that in this case V is
        reserved as workspace of length N*N.
  If JOBV = 'N'  V is not referenced.

LDV
  LDV is INTEGER
  The leading dimension of the array V,  LDV >= 1.
  If JOBV = 'V' or 'J' or 'W', then LDV >= N.

CWORK
  CWORK is COMPLEX array, dimension at least LWORK.

LWORK
  LWORK is INTEGER
  Length of CWORK to confirm proper allocation of workspace.
  LWORK depends on the job:

  1. If only SIGMA is needed ( JOBU.EQ.'N', JOBV.EQ.'N' ) and
   1.1 .. no scaled condition estimate required (JOBE.EQ.'N'):
       LWORK >= 2*N+1. This is the minimal requirement.
       ->> For optimal performance (blocked code) the optimal value
       is LWORK >= N + (N+1)*NB. Here NB is the optimal
       block size for CGEQP3 and CGEQRF.
       In general, optimal LWORK is computed as
       LWORK >= max(N+LWORK(CGEQP3),N+LWORK(CGEQRF)).
   1.2. .. an estimate of the scaled condition number of A is
       required (JOBA='E', or 'G'). In this case, LWORK the minimal
       requirement is LWORK >= N*N + 3*N.
       ->> For optimal performance (blocked code) the optimal value
       is LWORK >= max(N+(N+1)*NB, N*N+3*N).
       In general, the optimal length LWORK is computed as
       LWORK >= max(N+LWORK(CGEQP3),N+LWORK(CGEQRF), N+N*N+LWORK(CPOCON)).

  2. If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'),
       (JOBU.EQ.'N')
       -> the minimal requirement is LWORK >= 3*N.
```

```
      -> For optimal performance, LWORK >= max(N+(N+1)*NB, 3*N,2*N+N*NB),
         where NB is the optimal block size for CGEQP3, CGEQRF, CGELQ,
         CUNMLQ. In general, the optimal length LWORK is computed as
         LWORK >= max(N+LWORK(CGEQP3), N+LWORK(CPOCON), N+LWORK(CGESVJ),
                  N+LWORK(CGELQF), 2*N+LWORK(CGEQRF), N+LWORK(CUNMLQ)).

  3. If SIGMA and the left singular vectors are needed
      -> the minimal requirement is LWORK >= 3*N.
      -> For optimal performance:
      if JOBU.EQ.'U' :: LWORK >= max(3*N, N+(N+1)*NB, 2*N+N*NB),
      where NB is the optimal block size for CGEQP3, CGEQRF, CUNMQR.
      In general, the optimal length LWORK is computed as
      LWORK >= max(N+LWORK(CGEQP3),N+LWORK(CPOCON),
               2*N+LWORK(CGEQRF), N+LWORK(CUNMQR)).

  4. If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and
   4.1. if JOBV.EQ.'V' the minimal requirement is LWORK >= 5*N+2*N*N.
   4.2. if JOBV.EQ.'J' the minimal requirement is LWORK >= 4*N+N*N.
   In both cases, the allocated CWORK can accomodate blocked runs
   of CGEQP3, CGEQRF, CGELQF, SUNMQR, CUNMLQ.

RWORK
  RWORK is REAL array, dimension at least LRWORK.
  On exit,

  RWORK(1) = Determines the scaling factor SCALE = RWORK(2) / RWORK(1)
  such that SCALE*SVA(1:N) are the computed singular values
  of A. (See the description of SVA().)

  RWORK(2) = See the description of RWORK(1).

  RWORK(3) = SCONDA is an estimate for the condition number of
  column equilibrated A. (If JOBA .EQ. 'E' or 'G')
  SCONDA is an estimate of SQRT(||(R^* * R)^(-1)||_1).
  It is computed using SPOCON. It holds
  N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA
  where R is the triangular factor from the QRF of A.
  However, if R is truncated and the numerical rank is
  determined to be strictly smaller than N, SCONDA is
  returned as -1, thus indicating that the smallest
  singular values might be lost.

  If full SVD is needed, the following two condition numbers are
  useful for the analysis of the algorithm. They are provied for
  a developer/implementer who is familiar with the details of
  the method.

  RWORK(4) = an estimate of the scaled condition number of the
  triangular factor in the first QR factorization.
```

```
  RWORK(5) = an estimate of the scaled condition number of the
  triangular factor in the second QR factorization.
  The following two parameters are computed if JOBT .EQ. 'T'.
  They are provided for a developer/implementer who is familiar
  with the details of the method.

  RWORK(6) = the entropy of A^* * A :: this is the Shannon entropy
  of diag(A^* * A) / Trace(A^* * A) taken as point in the
  probability simplex.

  RWORK(7) = the entropy of A * A^*. (See the description of RWORK(6).)

LRWORK
  LRWORK is INTEGER
  Length of RWORK to confirm proper allocation of workspace.
  LRWORK depends on the job:

  1. If only singular values are requested i.e. if
     LSAME(JOBU,'N') .AND. LSAME(JOBV,'N') then:
    1.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
         then LRWORK = max( 7, N + 2 * M ).
    1.2. Otherwise, LRWORK  = max( 7, 2 * N ).

   2. If singular values with the right singular vectors are requested
      i.e. if
             (LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) .AND.
              .NOT.(LSAME(JOBU,'U').OR.LSAME(JOBU,'F'))
            then:
    2.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
            then LRWORK = max( 7, N + 2 * M ).
    2.2. Otherwise, LRWORK  = max( 7, 2 * N ).

   3. If singular values with the left singular vectors are requested, i.e. if
        (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND.
        .NOT.(LSAME(JOBV,'V').OR.LSAME(JOBV,'J'))
      then:
    3.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
          then LRWORK = max( 7, N + 2 * M ).
    3.2. Otherwise, LRWORK  = max( 7, 2 * N ).

   4. If singular values with both the left and the right singular vectors
      are requested, i.e. if
       (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND.
       (LSAME(JOBV,'V').OR.LSAME(JOBV,'J'))
      then:
    4.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
         then LRWORK = max( 7, N + 2 * M ).
    4.2. Otherwise, LRWORK  = max( 7, 2 * N ).

IWORK
```

```
  IWORK is INTEGER array, of dimension:
  If LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then
  the dimension of IWORK is max( 3, 2 * N + M ).
  Otherwise, the dimension of IWORK is
  -> max( 3, 2*N ) for full SVD
  -> max( 3, N ) for singular values only or singular
     values with one set of singular vectors (left or right)
  On exit,

  IWORK(1) = the numerical rank determined after the initial
             QR factorization with pivoting. See the descriptions
             of JOBA and JOBR.

  IWORK(2) = the number of the computed nonzero singular values

  IWORK(3) = if nonzero, a warning message:
             If IWORK(3).EQ.1 then some of the column norms of A
             were denormalized floats. The requested high accuracy
             is not warranted by the data.

INFO
  INFO is INTEGER
  < 0  : if INFO = -i, then the i-th argument had an illegal value.
  = 0 :  successfull exit;
  > 0 :  CGEJSV  did not converge in the maximal allowed number
         of sweeps. The computed values may be inaccurate.

  CGEJSV implements a preconditioned Jacobi SVD algorithm. It uses CGEQP3,
  CGEQRF, and CGELQF as preprocessors and preconditioners. Optionally, an
  additional row pivoting can be used as a preprocessor, which in some
  cases results in much higher accuracy. An example is matrix A with the
  structure A = D1 * C * D2, where D1, D2 are arbitrarily ill-conditioned
  diagonal matrices and C is well-conditioned matrix. In that case, complete
  pivoting in the first QR factorizations provides accuracy dependent on the
  condition number of C, and independent of D1, D2. Such higher accuracy is
  not completely understood theoretically, but it works well in practice.
  Further, if A can be written as A = B*D, with well-conditioned B and some
  diagonal D, then the high accuracy is guaranteed, both theoretically and
  in software, independent of D. For more details see [1], [2].

  The computational range for the singular values can be the full range
  ( UNDERFLOW,OVERFLOW ), provided that the machine arithmetic and the BLAS
  & LAPACK routines called by CGEJSV are implemented to work in that range.
  If that is not the case, then the restriction for safe computation with
  the singular values in the range of normalized IEEE numbers is that the
  spectral condition number kappa(A)=sigma_max(A)/sigma_min(A) does not
  overflow. This code (CGEJSV) is best used in this restricted range,
  meaning that singular values of magnitude below ||A||_2 / SLAMCH('O') are
  returned as zeros. See JOBR for details on this.
```

```
Further, this implementation is somewhat slower than the one described
in [1,2] due to replacement of some non-LAPACK components, and because
the choice of some tuning parameters in the iterative part (CGESVJ) is
left to the implementer on a particular machine.

The rank revealing QR factorization (in this code: CGEQP3) should be
implemented as in [3]. We have a new version of CGEQP3 under development
that is more robust than the current one in LAPACK, with a cleaner cut in
rank defficient cases. It will be available in the SIGMA library [4].

If M is much larger than N, it is obvious that the inital QRF with
column pivoting can be preprocessed by the QRF without pivoting. That
well known trick is not used in CGEJSV because in some cases heavy row
weighting can be treated with complete pivoting. The overhead in cases
M much larger than N is then only due to pivoting, but the benefits in
terms of accuracy have prevailed. The implementer/user can incorporate
this extra QRF step easily. The implementer can also improve data movement
(matrix transpose, matrix copy, matrix transposed copy) - this
implementation of CGEJSV uses only the simplest, naive data movement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgesdd (JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,
           LWORK, RWORK, IWORK, INFO)
           CGESDD

Function/Subroutine Documentation
   subroutine cgesdd (character JOBZ, integer M, integer N, complex,
```

```
      dimension( lda, * ) A, integer LDA, real, dimension( * ) S, complex,
      dimension( ldu, * ) U, integer LDU, complex, dimension( ldvt, * ) VT,
      integer LDVT, complex, dimension( * ) WORK, integer LWORK, real,
      dimension( * ) RWORK, integer, dimension( * ) IWORK, integer INFO)
      CGESDD

Purpose:
   CGESDD computes the singular value decomposition (SVD) of a complex
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors, by using divide-and-conquer method. The SVD is written

      A = U * SIGMA * conjugate-transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
   V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns VT = V**H, not V.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'A':  all M columns of U and all N rows of V**H are
           returned in the arrays U and VT;
   = 'S':  the first min(M,N) columns of U and the first
           min(M,N) rows of V**H are returned in the arrays U and VT;
   = 'O':  If M >= N, the first N columns of U are overwritten
           in the array A and all rows of V**H are returned in the array VT;
           otherwise, all columns of U are returned in the
           array U and the first M rows of V**H are overwritten
           in the array A;
   = 'N':  no columns of U or rows of V**H are computed.

 M
   M is INTEGER
   The number of rows of the input matrix A.  M >= 0.

 N
```

```
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if JOBZ = 'O',  A is overwritten with the first N columns
      of U (the left singular vectors, stored columnwise) if M >= N;
      A is overwritten with the first M rows
      of V**H (the right singular vectors, stored rowwise) otherwise.
      if JOBZ .ne. 'O', the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is REAL array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is COMPLEX array, dimension (LDU,UCOL)
  UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N;
  UCOL = min(M,N) if JOBZ = 'S'.
  If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M
  unitary matrix U;
  if JOBZ = 'S', U contains the first min(M,N) columns of U
  (the left singular vectors, stored columnwise);
  if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT
  VT is COMPLEX array, dimension (LDVT,N)
  If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the
  N-by-N unitary matrix V**H;
  if JOBZ = 'S', VT contains the first min(M,N) rows of
  V**H (the right singular vectors, stored rowwise);
  if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N;
  if JOBZ = 'S', LDVT >= min(M,N).
```

```
 WORK
   WORK is COMPLEX array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK >= 1.
   if JOBZ = 'N', LWORK >= 2*min(M,N)+max(M,N).
   if JOBZ = 'O',
       LWORK >= 2*min(M,N)*min(M,N)+2*min(M,N)+max(M,N).
   if JOBZ = 'S' or 'A',
       LWORK >= min(M,N)*min(M,N)+2*min(M,N)+max(M,N).
   For good performance, LWORK should generally be larger.

   If LWORK = -1, a workspace query is assumed.  The optimal
   size for the WORK array is calculated and stored in WORK(1),
   and no other work except argument checking is performed.

   RWORK
   RWORK is REAL array, dimension (MAX(1,LRWORK))
   If JOBZ = 'N', LRWORK >= 7*min(M,N).
   Otherwise,
   LRWORK >= min(M,N)*max(5*min(M,N)+7,2*max(M,N)+2*min(M,N)+1)

   IWORK
   IWORK is INTEGER array, dimension (8*min(M,N))

   INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  The updating process of SBDSDC did not converge.

SYNOPSIS
   Functions/Subroutines
       subroutine cgesvd (JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT,
           WORK, LWORK, RWORK, INFO)
            CGESVD computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine cgesvd (character JOBU, character JOBVT, integer M, integer N,
       complex, dimension( lda, * ) A, integer LDA, real, dimension( * ) S,
       complex, dimension( ldu, * ) U, integer LDU, complex, dimension( ldvt,
       * ) VT, integer LDVT, complex, dimension( * ) WORK, integer LWORK,
       real, dimension( * ) RWORK, integer INFO)
        CGESVD computes the singular value decomposition (SVD) for GE matrices

Purpose:
   CGESVD computes the singular value decomposition (SVD) of a complex
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

      A = U * SIGMA * conjugate-transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
   V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns V**H, not V.

Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'A':  all M columns of U are returned in array U:
   = 'S':  the first min(m,n) columns of U (the left singular
           vectors) are returned in the array U;
   = 'O':  the first min(m,n) columns of U (the left singular
           vectors) are overwritten on the array A;
   = 'N':  no columns of U (no left singular vectors) are computed.
```

```
JOBVT
  JOBVT is CHARACTER*1
  Specifies options for computing all or part of the matrix
  V**H:
  = 'A':  all N rows of V**H are returned in the array VT;
  = 'S':  the first min(m,n) rows of V**H (the right singular
          vectors) are returned in the array VT;
  = 'O':  the first min(m,n) rows of V**H (the right singular
          vectors) are overwritten on the array A;
  = 'N':  no rows of V**H (no right singular vectors) are computed.

  JOBVT and JOBU cannot both be 'O'.

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if JOBU = 'O',  A is overwritten with the first min(m,n)
        columns of U (the left singular vectors, stored columnwise);
  if JOBVT = 'O', A is overwritten with the first min(m,n)
        rows of V**H (the right singular vectors, stored rowwise);
  if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is REAL array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is COMPLEX array, dimension (LDU,UCOL)
  (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'.
  If JOBU = 'A', U contains the M-by-M unitary matrix U;
  if JOBU = 'S', U contains the first min(m,n) columns of U
  (the left singular vectors, stored columnwise);
  if JOBU = 'N' or 'O', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
```

```
  JOBU = 'S' or 'A', LDU >= M.

VT
  VT is COMPLEX array, dimension (LDVT,N)
  If JOBVT = 'A', VT contains the N-by-N unitary matrix V**H;
  if JOBVT = 'S', VT contains the first min(m,n) rows of
  V**H (the right singular vectors, stored rowwise);
  if JOBVT = 'N' or 'O', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >=  MAX(1,2*MIN(M,N)+MAX(M,N)).
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (5*min(M,N))
  On exit, if INFO > 0, RWORK(1:MIN(M,N)-1) contains the
  unconverged superdiagonal elements of an upper bidiagonal
  matrix B whose diagonal is in S (not necessarily sorted).
  B satisfies A = U * B * VT, so it has the same singular
  values as A, and singular vectors related by U and VT.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if CBDSQR did not converge, INFO specifies how many
        superdiagonals of an intermediate bidiagonal form B
        did not converge to zero. See the description of RWORK
        above for details.
