SYNOPSIS
   Functions/Subroutines
       subroutine cgesvdx (JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU,
           NS, S, U, LDU, VT, LDVT, WORK, LWORK, RWORK, IWORK, INFO)
            CGESVDX computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine cgesvdx (character JOBU, character JOBVT, character RANGE,
       integer M, integer N, complex, dimension( lda, * ) A, integer LDA, real
       VL, real VU, integer IL, integer IU, integer NS, real, dimension( * )
       S, complex, dimension( ldu, * ) U, integer LDU, complex, dimension(
       ldvt, * ) VT, integer LDVT, complex, dimension( * ) WORK, integer
       LWORK, real, dimension( * ) RWORK, integer, dimension( * ) IWORK,
       integer INFO)
        CGESVDX computes the singular value decomposition (SVD) for GE
       matrices

Purpose:
   CGESVDX computes the singular value decomposition (SVD) of a complex
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

    A = U * SIGMA * transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
```

```
   min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
   V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   CGESVDX uses an eigenvalue problem for obtaining the SVD, which
   allows for the computation of a subset of singular values and
   vectors. See SBDSVDX for details.

   Note that the routine returns V**T, not V.

Parameters:

   JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'V':  the first min(m,n) columns of U (the left singular
        vectors) or as specified by RANGE are returned in the array U;
   = 'N':  no columns of U (no left singular vectors) are computed.

 JOBVT
   JOBVT is CHARACTER*1
   Specifies options for computing all or part of the matrix
   V**T:
   = 'V':  the first min(m,n) rows of V**T (the right singular
        vectors) or as specified by RANGE are returned in the array VT;
   = 'N':  no rows of V**T (no right singular vectors) are computed.

 RANGE
   RANGE is CHARACTER*1
   = 'A': all singular values will be found.
   = 'V': all singular values in the half-open interval (VL,VU] will be found.
   = 'I': the IL-th through IU-th singular values will be found.

 M
   M is INTEGER
   The number of rows of the input matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the input matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the contents of A are destroyed.

 LDA
   LDA is INTEGER
```

```
  The leading dimension of the array A.  LDA >= max(1,M).

VL
  VL is REAL
  VL >=0.

VU
  VU is REAL
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for singular values. VU > VL.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest singular values to be returned.
  1 <= IL <= IU <= min(M,N), if min(M,N) > 0.
  Not referenced if RANGE = 'A' or 'V'.

NS
  NS is INTEGER
  The total number of singular values found,
  0 <= NS <= min(M,N).
  If RANGE = 'A', NS = min(M,N); if RANGE = 'I', NS = IU-IL+1.

S
  S is REAL array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is COMPLEX array, dimension (LDU,UCOL)
  If JOBU = 'V', U contains columns of U (the left singular
  vectors, stored columnwise) as specified by RANGE; if
  JOBU = 'N', U is not referenced.
  Note: The user must ensure that UCOL >= NS; if RANGE = 'V',
  the exact value of NS is not known ILQFin advance and an upper
  bound must be used.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'V', LDU >= M.

VT
  VT is COMPLEX array, dimension (LDVT,N)
  If JOBVT = 'V', VT contains the rows of V**T (the right singular
  vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N',
```

```
  VT is not referenced.
  Note: The user must ensure that LDVT >= NS; if RANGE = 'V',
  the exact value of NS is not known in advance and an upper
  bound must be used.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'V', LDVT >= NS (see above).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= MAX(1,MIN(M,N)*(MIN(M,N)+4)) for the paths (see
  comments inside the code):
  - PATH 1  (M much larger than N)
  - PATH 1t (N much larger than M)
  LWORK >= MAX(1,MIN(M,N)*2+MAX(M,N)) for the other paths.
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (MAX(1,LRWORK))
  LRWORK >= MIN(M,N)*(MIN(M,N)*2+15*MIN(M,N)).

IWORK
  IWORK is INTEGER array, dimension (12*MIN(M,N))
  If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0,
  then IWORK contains the indices of the eigenvectors that failed
  to converge in SBDSVDX/SSTEVX.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, then i eigenvectors failed to converge
        in SBDSVDX/SSTEVX. if INFO = N*2 + 1, an internal error occurred
        in SBDSVDX
```

       ZGEJSV

Purpose:

 JOBA
   JOBA is CHARACTER*1
   Specifies the level of accuracy:
   = 'C': This option works well (high relative accuracy) if A = B * D,
          with well-conditioned B and arbitrary diagonal matrix D.
          The accuracy cannot be spoiled by COLUMN scaling. The
          accuracy of the computed output depends on the condition of
          B, and the procedure aims at the best theoretical accuracy.
          The relative error max_{i=1:N}|d sigma_i| / sigma_i is
          bounded by f(M,N)*epsilon* cond(B), independent of D.
          The input matrix is preprocessed with the QRF with column
          pivoting. This initial preprocessing and preconditioning by
          a rank revealing QR factorization is common for all values of
          JOBA. Additional actions are specified as follows:
   = 'E': Computation as with 'C' with an additional estimate of the
          condition number of B. It provides a realistic error bound.
   = 'F': If A = D1 * C * D2 with ill-conditioned diagonal scalings
          D1, D2, and well-conditioned matrix C, this option gives
          higher accuracy than the 'C' option. If the structure of the
          input matrix is not known, and relative accuracy is
          desirable, then this option is advisable. The input matrix A
          is preprocessed with QR factorization with FULL (row and
          column) pivoting.
   = 'G'  Computation as with 'F' with an additional estimate of the
          condition number of B, where A=D*B. If A has heavily weighted
          rows, then using this condition number gives too pessimistic
```

```
          error bound.
   = 'A': Small singular values are the noise and the matrix is treated
          as numerically rank defficient. The error in the computed
          singular values is bounded by f(m,n)*epsilon*||A||.
          The computed SVD A = U * S * V^* restores A up to
          f(m,n)*epsilon*||A||.
          This gives the procedure the licence to discard (set to zero)
          all singular values below N*epsilon*||A||.
   = 'R': Similar as in 'A'. Rank revealing property of the initial
          QR factorization is used do reveal (using triangular factor)
          a gap sigma_{r+1} < epsilon * sigma_r in which case the
          numerical RANK is declared to be r. The SVD is computed with
          absolute error bounds, but more accurately than with 'A'.

Parameters:

   JOBU
   JOBU is CHARACTER*1
   Specifies whether to compute the columns of U:
   = 'U': N columns of U are returned in the array U.
   = 'F': full set of M left sing. vectors is returned in the array U.
   = 'W': U may be used as workspace of length M*N. See the description of U.
   = 'N': U is not computed.

 JOBV
   JOBV is CHARACTER*1
   Specifies whether to compute the matrix V:
   = 'V': N columns of V are returned in the array V; Jacobi rotations
            are not explicitly accumulated.
   = 'J': N columns of V are returned in the array V, but they are
            computed as the product of Jacobi rotations. This option is
            allowed only if JOBU .NE. 'N', i.e. in computing the full SVD.
   = 'W': V may be used as workspace of length N*N. See the description of V.
   = 'N': V is not computed.

 JOBR
   JOBR is CHARACTER*1
   Specifies the RANGE for the singular values. Issues the licence to
   set to zero small positive singular values if they are outside
   specified range. If A .NE. 0 is scaled so that the largest singular
   value of c*A is around SQRT(BIG), BIG=DLAMCH('O'), then JOBR issues
   the licence to kill columns of A whose norm in c*A is less than
   SQRT(SFMIN) (for JOBR.EQ.'R'), or less than SMALL=SFMIN/EPSLN,
   where SFMIN=DLAMCH('S'), EPSLN=DLAMCH('E').
   = 'N': Do not kill small columns of c*A. This option assumes that
          BLAS and QR factorizations and triangular solvers are
          implemented to work in that range. If the condition of A
          is greater than BIG, use ZGESVJ.
   = 'R': RESTRICTED range for sigma(c*A) is [SQRT(SFMIN), SQRT(BIG)]
          (roughly, as described above). This option is recommended.
```

```
                    ===========================
  For computing the singular values in the FULL range [SFMIN,BIG]
  use ZGESVJ.

JOBT
  JOBT is CHARACTER*1
  If the matrix is square then the procedure may determine to use
  transposed A if A^* seems to be better with respect to convergence.
  If the matrix is not square, JOBT is ignored. This is subject to
  changes in the future.
  The decision is based on two values of entropy over the adjoint
  orbit of A^* * A. See the descriptions of WORK(6) and WORK(7).
  = 'T': transpose if entropy test indicates possibly faster
         convergence of Jacobi process if A^* is taken as input. If A is
         replaced with A^*, then the row pivoting is included automatically.
  = 'N': do not speculate.
  This option can be used to compute only the singular values, or the
  full SVD (U, SIGMA and V). For only one set of singular vectors
  (U or V), the caller should provide both U and V, as one of the
  matrices is used as workspace if the matrix A is transposed.
  The implementer can easily remove this constraint and make the
  code more complicated. See the descriptions of U and V.

JOBP
  JOBP is CHARACTER*1
  Issues the licence to introduce structured perturbations to drown
  denormalized numbers. This licence should be active if the
  denormals are poorly implemented, causing slow computation,
  especially in cases of fast convergence (!). For details see [1,2].
  For the sake of simplicity, this perturbations are included only
  when the full SVD or only the singular values are requested. The
  implementer/user can easily add the perturbation for the cases of
  computing one set of singular vectors.
  = 'P': introduce perturbation
  = 'N': do not perturb

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A. M >= N >= 0.

A
  A is DOUBLE COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.

LDA
  LDA is INTEGER
```

```
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is DOUBLE PRECISION array, dimension (N)
  On exit,
  - For WORK(1)/WORK(2) = ONE: The singular values of A. During the
    computation SVA contains Euclidean column norms of the
    iterated matrices in the array A.
  - For WORK(1) .NE. WORK(2): The singular values of A are
    (WORK(1)/WORK(2)) * SVA(1:N). This factored form is used if
    sigma_max(A) overflows or if small singular values have been
    saved from underflow by scaling the input matrix A.
  - If JOBR='R' then some of the singular values may be returned
    as exact zeros obtained by "set to zero" because they are
    below the numerical rank threshold or are denormalized numbers.

U
  U is DOUBLE COMPLEX array, dimension ( LDU, N )
  If JOBU = 'U', then U contains on exit the M-by-N matrix of
       the left singular vectors.
  If JOBU = 'F', then U contains on exit the M-by-M matrix of
       the left singular vectors, including an ONB
       of the orthogonal complement of the Range(A).
  If JOBU = 'W'  .AND. (JOBV.EQ.'V' .AND. JOBT.EQ.'T' .AND. M.EQ.N),
       then U is used as workspace if the procedure
       replaces A with A^*. In that case, [V] is computed
       in U as left singular vectors of A^* and then
       copied back to the V array. This 'W' option is just
       a reminder to the caller that in this case U is
       reserved as workspace of length N*N.
  If JOBU = 'N'  U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U,  LDU >= 1.
  IF  JOBU = 'U' or 'F' or 'W',  then LDU >= M.

V
  V is DOUBLE COMPLEX array, dimension ( LDV, N )
  If JOBV = 'V', 'J' then V contains on exit the N-by-N matrix of
       the right singular vectors;
  If JOBV = 'W', AND (JOBU.EQ.'U' AND JOBT.EQ.'T' AND M.EQ.N),
       then V is used as workspace if the pprocedure
       replaces A with A^*. In that case, [U] is computed
       in V as right singular vectors of A^* and then
       copied back to the U array. This 'W' option is just
       a reminder to the caller that in this case V is
       reserved as workspace of length N*N.
  If JOBV = 'N'  V is not referenced.
```

```
LDV
  LDV is INTEGER
  The leading dimension of the array V,  LDV >= 1.
  If JOBV = 'V' or 'J' or 'W', then LDV >= N.

CWORK
  CWORK (workspace)
  CWORK is DOUBLE COMPLEX array, dimension at least LWORK.

LWORK
  LWORK is INTEGER
  Length of CWORK to confirm proper allocation of workspace.
  LWORK depends on the job:

  1. If only SIGMA is needed ( JOBU.EQ.'N', JOBV.EQ.'N' ) and
   1.1 .. no scaled condition estimate required (JOBE.EQ.'N'):
          LWORK >= 2*N+1. This is the minimal requirement.
      ->> For optimal performance (blocked code) the optimal value
          is LWORK >= N + (N+1)*NB. Here NB is the optimal
          block size for ZGEQP3 and ZGEQRF.
          In general, optimal LWORK is computed as
          LWORK >= max(N+LWORK(ZGEQP3),N+LWORK(ZGEQRF)).
   1.2. .. an estimate of the scaled condition number of A is
          required (JOBA='E', or 'G'). In this case, LWORK the minimal
          requirement is LWORK >= N*N + 3*N.
      ->> For optimal performance (blocked code) the optimal value
          is LWORK >= max(N+(N+1)*NB, N*N+3*N).
          In general, the optimal length LWORK is computed as
          LWORK >= max(N+LWORK(ZGEQP3),N+LWORK(ZGEQRF),
                   N+N*N+LWORK(CPOCON)).

  2. If SIGMA and the right singular vectors are needed (JOBV.EQ.'V'),
        (JOBU.EQ.'N')
    -> the minimal requirement is LWORK >= 3*N.
    -> For optimal performance, LWORK >= max(N+(N+1)*NB, 3*N,2*N+N*NB),
       where NB is the optimal block size for ZGEQP3, ZGEQRF, ZGELQ,
       CUNMLQ. In general, the optimal length LWORK is computed as
       LWORK >= max(N+LWORK(ZGEQP3), N+LWORK(CPOCON), N+LWORK(ZGESVJ),
                N+LWORK(ZGELQF), 2*N+LWORK(ZGEQRF), N+LWORK(CUNMLQ)).

  3. If SIGMA and the left singular vectors are needed
   -> the minimal requirement is LWORK >= 3*N.
   -> For optimal performance:
      if JOBU.EQ.'U' :: LWORK >= max(3*N, N+(N+1)*NB, 2*N+N*NB),
      where NB is the optimal block size for ZGEQP3, ZGEQRF, CUNMQR.
      In general, the optimal length LWORK is computed as
      LWORK >= max(N+LWORK(ZGEQP3),N+LWORK(CPOCON),
               2*N+LWORK(ZGEQRF), N+LWORK(CUNMQR)).

  4. If the full SVD is needed: (JOBU.EQ.'U' or JOBU.EQ.'F') and
```

```
   4.1. if JOBV.EQ.'V' the minimal requirement is LWORK >= 5*N+2*N*N.
   4.2. if JOBV.EQ.'J' the minimal requirement is LWORK >= 4*N+N*N.
  In both cases, the allocated CWORK can accomodate blocked runs
  of ZGEQP3, ZGEQRF, ZGELQF, SUNMQR, CUNMLQ.

RWORK
  RWORK is DOUBLE PRECISION array, dimension at least LRWORK.
  On exit,
  RWORK(1) = Determines the scaling factor SCALE = RWORK(2) / RWORK(1)
             such that SCALE*SVA(1:N) are the computed singular values
             of A. (See the description of SVA().)
  RWORK(2) = See the description of RWORK(1).
  RWORK(3) = SCONDA is an estimate for the condition number of
             column equilibrated A. (If JOBA .EQ. 'E' or 'G')
             SCONDA is an estimate of SQRT(||(R^* * R)^(-1)||_1).
             It is computed using SPOCON. It holds
             N^(-1/4) * SCONDA <= ||R^(-1)||_2 <= N^(1/4) * SCONDA
             where R is the triangular factor from the QRF of A.
             However, if R is truncated and the numerical rank is
             determined to be strictly smaller than N, SCONDA is
             returned as -1, thus indicating that the smallest
             singular values might be lost.

  If full SVD is needed, the following two condition numbers are
  useful for the analysis of the algorithm. They are provied for
  a developer/implementer who is familiar with the details of
  the method.

  RWORK(4) = an estimate of the scaled condition number of the
             triangular factor in the first QR factorization.
  RWORK(5) = an estimate of the scaled condition number of the
             triangular factor in the second QR factorization.

  The following two parameters are computed if JOBT .EQ. 'T'.
  They are provided for a developer/implementer who is familiar
  with the details of the method.
  RWORK(6) = the entropy of A^* * A :: this is the Shannon entropy
             of diag(A^* * A) / Trace(A^* * A) taken as point in the
             probability simplex.
  RWORK(7) = the entropy of A * A^*. (See the description of RWORK(6).)

LRWORK
  LRWORK is INTEGER
  Length of RWORK to confirm proper allocation of workspace.
  LRWORK depends on the job:

  1. If only singular values are requested i.e. if
     LSAME(JOBU,'N') .AND. LSAME(JOBV,'N')
     then:
   1.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
```

```
        then LRWORK = max( 7, N + 2 * M ).
   1.2. Otherwise, LRWORK  = max( 7, 2 * N ).
  2. If singular values with the right singular vectors are requested
     i.e. if
      (LSAME(JOBV,'V').OR.LSAME(JOBV,'J')) .AND.
       .NOT.(LSAME(JOBU,'U').OR.LSAME(JOBU,'F'))
     then:
   2.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
        then LRWORK = max( 7, N + 2 * M ).
   2.2. Otherwise, LRWORK  = max( 7, 2 * N ).
  3. If singular values with the left singular vectors are requested, i.e. if
      (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND.
      .NOT.(LSAME(JOBV,'V').OR.LSAME(JOBV,'J'))
     then:
   3.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
        then LRWORK = max( 7, N + 2 * M ).
   3.2. Otherwise, LRWORK  = max( 7, 2 * N ).
  4. If singular values with both the left and the right singular vectors
     are requested, i.e. if
      (LSAME(JOBU,'U').OR.LSAME(JOBU,'F')) .AND.
      (LSAME(JOBV,'V').OR.LSAME(JOBV,'J'))
     then:
   4.1. If LSAME(JOBT,'T') .OR. LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'),
        then LRWORK = max( 7, N + 2 * M ).
   4.2. Otherwise, LRWORK  = max( 7, 2 * N ).

IWORK
  IWORK is INTEGER array, of dimension:
  If LSAME(JOBA,'F') .OR. LSAME(JOBA,'G'), then
  the dimension of IWORK is max( 3, 2 * N + M ).
  Otherwise, the dimension of IWORK is
  -> max( 3, 2*N ) for full SVD
  -> max( 3, N ) for singular values only or singular
     values with one set of singular vectors (left or right)
  On exit,
  IWORK(1) = the numerical rank determined after the initial
             QR factorization with pivoting. See the descriptions
             of JOBA and JOBR.
  IWORK(2) = the number of the computed nonzero singular values
  IWORK(3) = if nonzero, a warning message:
             If IWORK(3).EQ.1 then some of the column norms of A
             were denormalized floats. The requested high accuracy
             is not warranted by the data.

INFO
  INFO is INTEGER
  < 0  : if INFO = -i, then the i-th argument had an illegal value.
  = 0 :  successfull exit;
  > 0 :  ZGEJSV  did not converge in the maximal allowed number
         of sweeps. The computed values may be inaccurate.
```

```
Further Details:
   ZGEJSV implements a preconditioned Jacobi SVD algorithm. It uses ZGEQP3,
   ZGEQRF, and ZGELQF as preprocessors and preconditioners. Optionally, an
   additional row pivoting can be used as a preprocessor, which in some
   cases results in much higher accuracy. An example is matrix A with the
   structure A = D1 * C * D2, where D1, D2 are arbitrarily ill-conditioned
   diagonal matrices and C is well-conditioned matrix. In that case, complete
   pivoting in the first QR factorizations provides accuracy dependent on the
   condition number of C, and independent of D1, D2. Such higher accuracy is
   not completely understood theoretically, but it works well in practice.
   Further, if A can be written as A = B*D, with well-conditioned B and some
   diagonal D, then the high accuracy is guaranteed, both theoretically and
   in software, independent of D. For more details see [1], [2].
   The computational range for the singular values can be the full range
   ( UNDERFLOW,OVERFLOW ), provided that the machine arithmetic and the BLAS
   & LAPACK routines called by ZGEJSV are implemented to work in that range.
   If that is not the case, then the restriction for safe computation with
   the singular values in the range of normalized IEEE numbers is that the
   spectral condition number kappa(A)=sigma_max(A)/sigma_min(A) does not
   overflow. This code (ZGEJSV) is best used in this restricted range,
   meaning that singular values of magnitude below ||A||_2 / DLAMCH('O') are
   returned as zeros. See JOBR for details on this.
   Further, this implementation is somewhat slower than the one described
   in [1,2] due to replacement of some non-LAPACK components, and because
   the choice of some tuning parameters in the iterative part (ZGESVJ) is
   left to the implementer on a particular machine.
   The rank revealing QR factorization (in this code: ZGEQP3) should be
   implemented as in [3]. We have a new version of ZGEQP3 under development
   that is more robust than the current one in LAPACK, with a cleaner cut in
   rank defficient cases. It will be available in the SIGMA library [4].
   If M is much larger than N, it is obvious that the inital QRF with
   column pivoting can be preprocessed by the QRF without pivoting. That
   well known trick is not used in ZGEJSV because in some cases heavy row
   weighting can be treated with complete pivoting. The overhead in cases
   M much larger than N is then only due to pivoting, but the benefits in
   terms of accuracy have prevailed. The implementer/user can incorporate
   this extra QRF step easily. The implementer can also improve data movement
   (matrix transpose, matrix copy, matrix transposed copy) - this
   implementation of ZGEJSV uses only the simplest, naive data movement.

SYNOPSIS
   Functions/Subroutines
       subroutine zgesdd (JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,
           LWORK, RWORK, IWORK, INFO)
           ZGESDD

Function/Subroutine Documentation
   subroutine zgesdd (character JOBZ, integer M, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, double precision, dimension( * ) S,
       complex*16, dimension( ldu, * ) U, integer LDU, complex*16, dimension(
       ldvt, * ) VT, integer LDVT, complex*16, dimension( * ) WORK, integer
       LWORK, double precision, dimension( * ) RWORK, integer, dimension( * )
```

```
       IWORK, integer INFO)
       ZGESDD

Purpose:
   ZGESDD computes the singular value decomposition (SVD) of a complex
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors, by using divide-and-conquer method. The SVD is written

   A = U * SIGMA * conjugate-transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
   V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns VT = V**H, not V.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'A':  all M columns of U and all N rows of V**H are
           returned in the arrays U and VT;
   = 'S':  the first min(M,N) columns of U and the first
           min(M,N) rows of V**H are returned in the arrays U and VT;
   = 'O':  If M >= N, the first N columns of U are overwritten
           in the array A and all rows of V**H are returned in the array VT;
           otherwise, all columns of U are returned in the
           array U and the first M rows of V**H are overwritten
           in the array A;
   = 'N':  no columns of U or rows of V**H are computed.

 M
   M is INTEGER
   The number of rows of the input matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the input matrix A.  N >= 0.
```

```
A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if JOBZ = 'O',  A is overwritten with the first N columns
       of U (the left singular vectors, stored columnwise) if M >= N;
       A is overwritten with the first M rows
       of V**H (the right singular vectors, stored rowwise) otherwise.
  if JOBZ .ne. 'O', the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is COMPLEX*16 array, dimension (LDU,UCOL)
  UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N;
  UCOL = min(M,N) if JOBZ = 'S'.
  If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M
  unitary matrix U;
  if JOBZ = 'S', U contains the first min(M,N) columns of U
  (the left singular vectors, stored columnwise);
  if JOBZ = 'O' and M >= N, or JOBZ = 'N', U is not referenced.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT
  VT is COMPLEX*16 array, dimension (LDVT,N)
  If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the
  N-by-N unitary matrix V**H;
  if JOBZ = 'S', VT contains the first min(M,N) rows of
  V**H (the right singular vectors, stored rowwise);
  if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N;
  if JOBZ = 'S', LDVT >= min(M,N).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK >= 1.
   if JOBZ = 'N', LWORK >= 2*min(M,N)+max(M,N).
   if JOBZ = 'O',
      LWORK >= 2*min(M,N)*min(M,N)+2*min(M,N)+max(M,N).
   if JOBZ = 'S' or 'A',
      LWORK >= min(M,N)*min(M,N)+2*min(M,N)+max(M,N).
   For good performance, LWORK should generally be larger.

   If LWORK = -1, a workspace query is assumed.  The optimal
   size for the WORK array is calculated and stored in WORK(1),
   and no other work except argument checking is performed.

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (MAX(1,LRWORK))
   If JOBZ = 'N', LRWORK >= 7*min(M,N).
   Otherwise,
   LRWORK >= min(M,N)*max(5*min(M,N)+7,2*max(M,N)+2*min(M,N)+1)

 IWORK
   IWORK is INTEGER array, dimension (8*min(M,N))

 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  The updating process of DBDSDC did not converge.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgesvd (JOBU, JOBVT, M, N, A, LDA, S, U, LDU, VT, LDVT,
           WORK, LWORK, RWORK, INFO)
            ZGESVD computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine zgesvd (character JOBU, character JOBVT, integer M, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) S, complex*16, dimension( ldu, * ) U, integer LDU,
       complex*16, dimension( ldvt, * ) VT, integer LDVT, complex*16,
       dimension( * ) WORK, integer LWORK, double precision, dimension( * )
       RWORK, integer INFO)
        ZGESVD computes the singular value decomposition (SVD) for GE matrices

Purpose:
   ZGESVD computes the singular value decomposition (SVD) of a complex
   M-by-N matrix A, optionally computing the left and/or right singular
   vectors. The SVD is written

   A = U * SIGMA * conjugate-transpose(V)

   where SIGMA is an M-by-N matrix which is zero except for its
   min(m,n) diagonal elements, U is an M-by-M unitary matrix, and
   V is an N-by-N unitary matrix.  The diagonal elements of SIGMA
   are the singular values of A; they are real and non-negative, and
   are returned in descending order.  The first min(m,n) columns of
   U and V are the left and right singular vectors of A.

   Note that the routine returns V**H, not V.

Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'A':  all M columns of U are returned in array U:
   = 'S':  the first min(m,n) columns of U (the left singular
           vectors) are returned in the array U;
   = 'O':  the first min(m,n) columns of U (the left singular
           vectors) are overwritten on the array A;
```

```
  = 'N':  no columns of U (no left singular vectors) are computed.

JOBVT
  JOBVT is CHARACTER*1
  Specifies options for computing all or part of the matrix V**H:
  = 'A':  all N rows of V**H are returned in the array VT;
  = 'S':  the first min(m,n) rows of V**H (the right singular
          vectors) are returned in the array VT;
  = 'O':  the first min(m,n) rows of V**H (the right singular
          vectors) are overwritten on the array A;
  = 'N':  no rows of V**H (no right singular vectors) are computed.

  JOBVT and JOBU cannot both be 'O'.

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if JOBU = 'O',  A is overwritten with the first min(m,n)
       columns of U (the left singular vectors, stored columnwise);
  if JOBVT = 'O', A is overwritten with the first min(m,n)
       rows of V**H (the right singular vectors, stored rowwise);
  if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A
       are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is COMPLEX*16 array, dimension (LDU,UCOL)
  (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'.
  If JOBU = 'A', U contains the M-by-M unitary matrix U;
  if JOBU = 'S', U contains the first min(m,n) columns of U
  (the left singular vectors, stored columnwise);
  if JOBU = 'N' or 'O', U is not referenced.

LDU
```

```
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'S' or 'A', LDU >= M.

VT
  VT is COMPLEX*16 array, dimension (LDVT,N)
  If JOBVT = 'A', VT contains the N-by-N unitary matrix V**H;
  if JOBVT = 'S', VT contains the first min(m,n) rows of
  V**H (the right singular vectors, stored rowwise);
  if JOBVT = 'N' or 'O', VT is not referenced.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >=  MAX(1,2*MIN(M,N)+MAX(M,N)).
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (5*min(M,N))
  On exit, if INFO > 0, RWORK(1:MIN(M,N)-1) contains the
  unconverged superdiagonal elements of an upper bidiagonal
  matrix B whose diagonal is in S (not necessarily sorted).
  B satisfies A = U * B * VT, so it has the same singular
  values as A, and singular vectors related by U and VT.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if ZBDSQR did not converge, INFO specifies how many
        superdiagonals of an intermediate bidiagonal form B
        did not converge to zero. See the description of RWORK
        above for details.

SYNOPSIS
   Functions/Subroutines
       subroutine zgesvdx (JOBU, JOBVT, RANGE, M, N, A, LDA, VL, VU, IL, IU,
           NS, S, U, LDU, VT, LDVT, WORK, LWORK, RWORK, IWORK, INFO)
            ZGESVDX computes the singular value decomposition (SVD) for GE
           matrices

Function/Subroutine Documentation
   subroutine zgesvdx (character JOBU, character JOBVT, character RANGE,
       integer M, integer N, complex*16, dimension( lda, * ) A, integer LDA,
       double precision VL, double precision VU, integer IL, integer IU,
       integer NS, double precision, dimension( * ) S, complex*16, dimension(
       ldu, * ) U, integer LDU, complex*16, dimension( ldvt, * ) VT, integer
       LDVT, complex*16, dimension( * ) WORK, integer LWORK, double precision,
       dimension( * ) RWORK, integer, dimension( * ) IWORK, integer INFO)
        ZGESVDX computes the singular value decomposition (SVD) for GE
       matrices

Parameters:

 JOBU
   JOBU is CHARACTER*1
   Specifies options for computing all or part of the matrix U:
   = 'V':  the first min(m,n) columns of U (the left singular
           vectors) or as specified by RANGE are returned in the array U;
   = 'N':  no columns of U (no left singular vectors) are computed.
```

```
JOBVT
  JOBVT is CHARACTER*1
  Specifies options for computing all or part of the matrix
  V**T:
  = 'V':  the first min(m,n) rows of V**T (the right singular
          vectors) or as specified by RANGE are returned in the array VT;
  = 'N':  no rows of V**T (no right singular vectors) are computed.

RANGE
  RANGE is CHARACTER*1
  = 'A': all singular values will be found.
  = 'V': all singular values in the half-open interval (VL,VU] will be found.
  = 'I': the IL-th through IU-th singular values will be found.

M
  M is INTEGER
  The number of rows of the input matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the contents of A are destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

VL
  VL is DOUBLE PRECISION
  VL >=0.

VU
  VU is DOUBLE PRECISION
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for singular values. VU > VL.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest singular values to be returned.
  1 <= IL <= IU <= min(M,N), if min(M,N) > 0.
```

```
  Not referenced if RANGE = 'A' or 'V'.

NS
  NS is INTEGER
  The total number of singular values found,
  0 <= NS <= min(M,N).
  If RANGE = 'A', NS = min(M,N); if RANGE = 'I', NS = IU-IL+1.

S
  S is DOUBLE PRECISION array, dimension (min(M,N))
  The singular values of A, sorted so that S(i) >= S(i+1).

U
  U is COMPLEX*16 array, dimension (LDU,UCOL)
  If JOBU = 'V', U contains columns of U (the left singular
  vectors, stored columnwise) as specified by RANGE; if
  JOBU = 'N', U is not referenced.
  Note: The user must ensure that UCOL >= NS; if RANGE = 'V',
  the exact value of NS is not known ILQFin advance and an upper
  bound must be used.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= 1; if
  JOBU = 'V', LDU >= M.

VT
  VT is COMPLEX*16 array, dimension (LDVT,N)
  If JOBVT = 'V', VT contains the rows of V**T (the right singular
  vectors, stored rowwise) as specified by RANGE; if JOBVT = 'N',
  VT is not referenced.
  Note: The user must ensure that LDVT >= NS; if RANGE = 'V',
  the exact value of NS is not known in advance and an upper
  bound must be used.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= 1; if
  JOBVT = 'V', LDVT >= NS (see above).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= MAX(1,MIN(M,N)*(MIN(M,N)+4)) for the paths (see
  comments inside the code):
  - PATH 1  (M much larger than N)
```

```
  - PATH 1t (N much larger than M)
  LWORK >= MAX(1,MIN(M,N)*2+MAX(M,N)) for the other paths.
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (MAX(1,LRWORK))
  LRWORK >= MIN(M,N)*(MIN(M,N)*2+15*MIN(M,N)).

IWORK
  IWORK is INTEGER array, dimension (12*MIN(M,N))
  If INFO = 0, the first NS elements of IWORK are zero. If INFO > 0,
  then IWORK contains the indices of the eigenvectors that failed
  to converge in DBDSVDX/DSTEVX.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, then i eigenvectors failed to converge
        in DBDSVDX/DSTEVX.
        if INFO = N*2 + 1, an internal error occurred in DBDSVDX
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgebak (JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
           DGEBAK

Function/Subroutine Documentation
   subroutine dgebak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, double precision, dimension( * ) SCALE, integer M, double
       precision, dimension( ldv, * ) V, integer LDV, integer INFO)
       DGEBAK

Purpose:
   DGEBAK forms the right or left eigenvectors of a real general matrix
   by backward transformation on the computed eigenvectors of the
   balanced matrix output by DGEBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N', do nothing, return immediately;
   = 'P', do backward transformation for permutation only;
   = 'S', do backward transformation for scaling only;
   = 'B', do backward transformations for both permutation and scaling.
   JOB must be the same as the argument JOB supplied to DGEBAL.

 SIDE
   SIDE is CHARACTER*1
   = 'R':  V contains right eigenvectors;
   = 'L':  V contains left eigenvectors.

 N
   N is INTEGER
   The number of rows of the matrix V.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   The integers ILO and IHI determined by DGEBAL.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 SCALE
```

```
  SCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutation and scaling factors, as returned by DGEBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is DOUBLE PRECISION array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by DHSEIN or DTREVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the array V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgebal (JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
           DGEBAL

Function/Subroutine Documentation
   subroutine dgebal (character JOB, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer ILO, integer IHI, double precision,
       dimension( * ) SCALE, integer INFO)
       DGEBAL

Purpose:
   DGEBAL balances a general real matrix A.  This involves, first,
   permuting A by a similarity transformation to isolate eigenvalues
   in the first 1 to ILO-1 and last IHI+1 to N elements on the
   diagonal; and second, applying a diagonal similarity transformation
   to rows and columns ILO to IHI to make the rows and columns as
   close in norm as possible.  Both steps are optional.

   Balancing may reduce the 1-norm of the matrix, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A:
   = 'N':  none:  simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N;
   = 'P':  permute only;
   = 'S':  scale only;
```

```
  = 'B':  both permute and scale.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE array, dimension (LDA,N)
  On entry, the input matrix A.
  On exit,  A is overwritten by the balanced matrix.
  If JOB = 'N', A is not referenced.
  See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE
  SCALE is DOUBLE array, dimension (N)
  Details of the permutations and scaling factors applied to
  A.  If P(j) is the index of the row and column interchanged
  with row and column j and D(j) is the scaling factor
  applied to row and column j, then
  SCALE(j) = P(j)    for j = 1,...,ILO-1
           = D(j)    for j = ILO,...,IHI
           = P(j)    for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:
  The permutations consist of row and column interchanges which put
  the matrix in the form

                        ( T1   X   Y  )
               P A P = (  0   B   Z  )
                        (  0   0   T2 )
```

```
where T1 and T2 are upper triangular matrices whose eigenvalues lie
along the diagonal.  The column indices ILO and IHI mark the starting
and ending columns of the submatrix B. Balancing consists of applying
a diagonal similarity transformation inv(D) * B * D to make the
1-norms of each row of B and its corresponding column nearly equal.
The output matrix is

             ( T1     X*D          Y    )
             (  0  inv(D)*B*D  inv(D)*Z ).
             (  0      0           T2   )

Information about the permutations P and the diagonal matrix D is
returned in the vector SCALE.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgebd2 (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
           DGEBD2 reduces a general matrix to bidiagonal form using an
           unblocked algorithm.

Function/Subroutine Documentation
   subroutine dgebd2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision, dimension( * ) TAUQ,
       double precision, dimension( * ) TAUP, double precision, dimension( * )
       WORK, integer INFO)
       DGEBD2 reduces a general matrix to bidiagonal form using an unblocked
       algorithm.

Purpose:
   DGEBD2 reduces a real general m by n matrix A to upper or lower
   bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
     overwritten with the upper bidiagonal matrix B; the
```

```
    elements below the diagonal, with the array TAUQ, represent
    the orthogonal matrix Q as a product of elementary
    reflectors, and the elements above the first superdiagonal,
    with the array TAUP, represent the orthogonal matrix P as
    a product of elementary reflectors;
  if m < n, the diagonal and the first subdiagonal are
    overwritten with the lower bidiagonal matrix B; the
    elements below the first subdiagonal, with the array TAUQ,
    represent the orthogonal matrix Q as a product of
    elementary reflectors, and the elements above the diagonal,
    with the array TAUP, represent the orthogonal matrix P as
    a product of elementary reflectors.
  See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

D
  D is DOUBLE PRECISION array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E
  E is DOUBLE PRECISION array, dimension (min(M,N)-1)
  The off-diagonal elements of the bidiagonal matrix B:
  if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
  if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ
  TAUQ is DOUBLE PRECISION array dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the orthogonal matrix Q. See Further Details.

TAUP
  TAUP is DOUBLE PRECISION array, dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the orthogonal matrix P. See Further Details.

WORK
  WORK is DOUBLE PRECISION array, dimension (max(M,N))

INFO
  INFO is INTEGER
  = 0: successful exit.
  < 0: if INFO = -i, the i-th argument had an illegal value.

Further Details:
  The matrices Q and P are represented as products of elementary
  reflectors:
```

```
If m >= n,

            Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

Each H(i) and G(i) has the form:

            H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

where tauq and taup are real scalars, and v and u are real vectors;
v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i);
u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

If m < n,

            Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

            H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

where tauq and taup are real scalars, and v and u are real vectors;
v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

          m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

            (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
            (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
            (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
            (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
            (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
            (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal elements of B, vi
denotes an element of the vector defining H(i), and ui an element of
the vector defining G(i).

SYNOPSIS
   Functions/Subroutines
       subroutine dgebrd (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
           DGEBRD

Function/Subroutine Documentation
   subroutine dgebrd (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision, dimension( * ) TAUQ,
       double precision, dimension( * ) TAUP, double precision, dimension( * )
       WORK, integer LWORK, integer INFO)
       DGEBRD

Purpose:
   DGEBRD reduces a general real M-by-N matrix A to upper or lower
   bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.
```

```
   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
     overwritten with the upper bidiagonal matrix B; the
     elements below the diagonal, with the array TAUQ, represent
     the orthogonal matrix Q as a product of elementary
     reflectors, and the elements above the first superdiagonal,
     with the array TAUP, represent the orthogonal matrix P as
     a product of elementary reflectors;
   if m < n, the diagonal and the first subdiagonal are
     overwritten with the lower bidiagonal matrix B; the
     elements below the first subdiagonal, with the array TAUQ,
     represent the orthogonal matrix Q as a product of
     elementary reflectors, and the elements above the diagonal,
     with the array TAUP, represent the orthogonal matrix P as
     a product of elementary reflectors.
   See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 D
   D is DOUBLE PRECISION array, dimension (min(M,N))
   The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

 E
   E is DOUBLE PRECISION array, dimension (min(M,N)-1)
   The off-diagonal elements of the bidiagonal matrix B:
   if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
   if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

 TAUQ
   TAUQ is DOUBLE PRECISION array dimension (min(M,N))
   The scalar factors of the elementary reflectors which
```

```
  represent the orthogonal matrix Q. See Further Details.

 TAUP
   TAUP is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors which
   represent the orthogonal matrix P. See Further Details.

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of the array WORK.  LWORK >= max(1,M,N).
   For optimum performance LWORK >= (M+N)*NB, where NB
   is the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:
   The matrices Q and P are represented as products of elementary
   reflectors:

   If m >= n,

                Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

   Each H(i) and G(i) has the form:

                H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

   where tauq and taup are real scalars, and v and u are real vectors;
   v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i);
   u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
   tauq is stored in TAUQ(i) and taup in TAUP(i).

   If m < n,

                Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

   Each H(i) and G(i) has the form:
```

```
              H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

   where tauq and taup are real scalars, and v and u are real vectors;
   v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
   u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);
   tauq is stored in TAUQ(i) and taup in TAUP(i).

   The contents of A on exit are illustrated by the following examples:

            m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

              (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
              (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
              (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
              (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
              (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
              (  v1  v2  v3  v4  v5 )

   where d and e denote diagonal and off-diagonal elements of B, vi
   denotes an element of the vector defining H(i), and ui an element of
   the vector defining G(i).

SYNOPSIS
   Functions/Subroutines
       subroutine dgecon (NORM, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
           DGECON

Function/Subroutine Documentation
   subroutine dgecon (character NORM, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision ANORM, double precision
       RCOND, double precision, dimension( * ) WORK, integer, dimension( * )
       IWORK, integer INFO)
       DGECON

Purpose:
   DGECON estimates the reciprocal of the condition number of a general
   real matrix A, in either the 1-norm or the infinity-norm, using
   the LU factorization computed by DGETRF.
```

```
  An estimate is obtained for norm(inv(A)), and the reciprocal of the
  condition number is computed as
     RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The factors L and U from the factorization A = P*L*U
   as computed by DGETRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 ANORM
   ANORM is DOUBLE PRECISION
   If NORM = '1' or 'O', the 1-norm of the original matrix A.
   If NORM = 'I', the infinity-norm of the original matrix A.

 RCOND
   RCOND is DOUBLE PRECISION
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(norm(A) * norm(inv(A))).

 WORK
   WORK is DOUBLE PRECISION array, dimension (4*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgeequ (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           DGEEQU

Function/Subroutine Documentation
   subroutine dgeequ (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) R, double
       precision, dimension( * ) C, double precision ROWCND, double precision
       COLCND, double precision AMAX, integer INFO)
       DGEEQU

Purpose:
   DGEEQU computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

   R(i) and C(j) are restricted to be between SMLNUM = smallest safe
   number and BIGNUM = largest safe number.  Use of these scaling
   factors is not guaranteed to reduce the condition number of A but
```

```
   works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The M-by-N matrix whose equilibration factors are to be computed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 R
   R is DOUBLE PRECISION array, dimension (M)
   If INFO = 0 or INFO > M, R contains the row scale factors for A.

 C
   C is DOUBLE PRECISION array, dimension (N)
   If INFO = 0,  C contains the column scale factors for A.

 ROWCND
   ROWCND is DOUBLE PRECISION
   If INFO = 0 or INFO > M, ROWCND contains the ratio of the
   smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
   AMAX is neither too large nor too small, it is not worth scaling by R.

 COLCND
   COLCND is DOUBLE PRECISION
   If INFO = 0, COLCND contains the ratio of the smallest
   C(i) to the largest C(i).  If COLCND >= 0.1, it is not
   worth scaling by C.

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix should be scaled.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i,  and i is
```

```
     <= M:  the i-th row of A is exactly zero
     >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgeequb (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           DGEEQUB

Function/Subroutine Documentation
   subroutine dgeequb (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) R, double
       precision, dimension( * ) C, double precision ROWCND, double precision
       COLCND, double precision AMAX, integer INFO)
```

```
      DGEEQUB

Purpose:
   DGEEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from DGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The M-by-N matrix whose equilibration factors are to be computed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 R
   R is DOUBLE PRECISION array, dimension (M)
   If INFO = 0 or INFO > M, R contains the row scale factors for A.

 C
   C is DOUBLE PRECISION array, dimension (N)
   If INFO = 0,  C contains the column scale factors for A.

 ROWCND
   ROWCND is DOUBLE PRECISION
   If INFO = 0 or INFO > M, ROWCND contains the ratio of the
```

```
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

  COLCND
  COLCND is DOUBLE PRECISION
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

 AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i,  and i is
    <= M:  the i-th row of A is exactly zero
    >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgehd2 (N, ILO, IHI, A, LDA, TAU, WORK, INFO)
           DGEHD2 reduces a general square matrix to upper Hessenberg form
           using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine dgehd2 (integer N, integer ILO, integer IHI, double precision,
```

```
      dimension( lda, * ) A, integer LDA, double precision, dimension( * )
      TAU, double precision, dimension( * ) WORK, integer INFO)
      DGEHD2 reduces a general square matrix to upper Hessenberg form using
      an unblocked algorithm.

Purpose:
   DGEHD2 reduces a real general matrix A to upper Hessenberg form H by
   an orthogonal similarity transformation:  Q**T * A * Q = H .

 Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to DGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= max(1,N).

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the n by n general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the orthogonal matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is DOUBLE PRECISION array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit.
```

```
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:
   The matrix Q is represented as a product of (ihi-ilo) elementary
   reflectors

                Q = H(ilo) H(ilo+1) . . . H(ihi-1).

   Each H(i) has the form

                H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
   exit in A(i+2:ihi,i), and tau in TAU(i).

   The contents of A are illustrated by the following example, with
   n = 7, ilo = 2 and ihi = 6:

             on entry,                        on exit,

             ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
             (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
             (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
             (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
             (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
             (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
             (                       a )    (                          a )

   where a denotes an element of the original matrix A, h denotes a
   modified element of the upper Hessenberg matrix H, and vi denotes an
   element of the vector defining H(i).

SYNOPSIS
   Functions/Subroutines
       subroutine dgehrd (N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
           DGEHRD

Function/Subroutine Documentation
   subroutine dgehrd (integer N, integer ILO, integer IHI, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( * )
       TAU, double precision, dimension( * ) WORK, integer LWORK, integer
       INFO)
       DGEHRD

Purpose:
   DGEHRD reduces a real general matrix A to upper Hessenberg form H by
   an orthogonal similarity transformation:  Q**T * A * Q = H .

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to DGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.
```

```
 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the orthogonal matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is DOUBLE PRECISION array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further
   Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

 WORK
   WORK is DOUBLE PRECISION array, dimension (LWORK)
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of the array WORK.  LWORK >= max(1,N).
   For good performance, LWORK should generally be larger.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:
   The matrix Q is represented as a product of (ihi-ilo) elementary
   reflectors

                Q = H(ilo) H(ilo+1) . . . H(ihi-1).

   Each H(i) has the form

                H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
   exit in A(i+2:ihi,i), and tau in TAU(i).
```

```
The contents of A are illustrated by the following example, with
n = 7, ilo = 2 and ihi = 6:

          on entry,                        on exit,

          ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
          (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
          (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
          (                         a )    (                          a )

where a denotes an element of the original matrix A, h denotes a
modified element of the upper Hessenberg matrix H, and vi denotes an
element of the vector defining H(i).

This file is a slight modification of LAPACK-3.0's DGEHRD
subroutine incorporating improvements proposed by Quintana-Orti and
Van de Geijn (2006). (See DLAHR2.)

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgelq2 (M, N, A, LDA, TAU, WORK, INFO)
           DGELQ2 computes the LQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine dgelq2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer INFO)
       DGELQ2 computes the LQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   DGELQ2 computes an LQ factorization of a real m by n matrix A:
   A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n matrix A.
```

```
   On exit, the elements on and below the diagonal of the array
   contain the m by min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

               Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on exit in A(i,i+1:n),
   and tau in TAU(i).

====================================================================
dgelqf examples
====================================================================

====================================================================
Man Page Details
====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgelqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           DGELQF

Function/Subroutine Documentation
   subroutine dgelqf (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DGELQF

Purpose:
   DGELQF computes an LQ factorization of a real M-by-N matrix A: A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and below the diagonal of the array
   contain the m-by-min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).
```

```
 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,M).
   For optimum performance LWORK >= M*NB, where NB is the
   optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

               Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on exit in A(i,i+1:n),
   and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgemqrt (SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC,
           WORK, INFO)
           DGEMQRT

Function/Subroutine Documentation
   subroutine dgemqrt (character SIDE, character TRANS, integer M, integer N,
       integer K, integer NB, double precision, dimension( ldv, * ) V, integer
       LDV, double precision, dimension( ldt, * ) T, integer LDT, double
       precision, dimension( ldc, * ) C, integer LDC, double precision,
       dimension( * ) WORK, integer INFO)
       DGEMQRT

Purpose:
   DGEMQRT overwrites the general real M-by-N matrix C with
```

```
                          SIDE = 'L'     SIDE = 'R'
          TRANS = 'N':      Q C            C Q
          TRANS = 'T':   Q**T C            C Q**T

  where Q is a real orthogonal matrix defined as the product of K
  elementary reflectors:

                Q = H(1) H(2) . . . H(K) = I - V T V**T

  generated using the compact WY representation as returned by DGEQRT.

  Q is of order M if SIDE = 'L' and of order N  if SIDE = 'R'.

Parameters:

 SIDE
  SIDE is CHARACTER*1
  = 'L': apply Q or Q**T from the Left;
  = 'R': apply Q or Q**T from the Right.

 TRANS
  TRANS is CHARACTER*1
  = 'N':  No transpose, apply Q;
  = 'C':  Transpose, apply Q**T.

 M
  M is INTEGER
  The number of rows of the matrix C. M >= 0.

 N
  N is INTEGER
  The number of columns of the matrix C. N >= 0.

 K
  K is INTEGER
  The number of elementary reflectors whose product defines the matrix Q.
  If SIDE = 'L', M >= K >= 0;
  if SIDE = 'R', N >= K >= 0.

 NB
  NB is INTEGER
  The block size used for the storage of T.  K >= NB >= 1.
  This must be the same value of NB used to generate T in CGEQRT.

 V
  V is DOUBLE PRECISION array, dimension (LDV,K)
  The i-th column must contain the vector which defines the
  elementary reflector H(i), for i = 1,2,...,k, as returned by
  CGEQRT in the first K columns of its array argument A.
```

```
LDV
  LDV is INTEGER
  The leading dimension of the array V.
  If SIDE = 'L', LDA >= max(1,M);
  if SIDE = 'R', LDA >= max(1,N).

T
  T is DOUBLE PRECISION array, dimension (LDT,K)
  The upper triangular factors of the block reflectors
  as returned by CGEQRT, stored as a NB-by-N matrix.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= NB.

C
  C is DOUBLE PRECISION array, dimension (LDC,N)
  On entry, the M-by-N matrix C.
  On exit, C is overwritten by Q C, Q**T C, C Q**T or C Q.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M).

WORK
  WORK is DOUBLE PRECISION array. The dimension of
  WORK is N*NB if SIDE = 'L', or  M*NB if SIDE = 'R'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgeql2 (M, N, A, LDA, TAU, WORK, INFO)
           DGEQL2 computes the QL factorization of a general rectangular
           matrix using an unblocked algorithm.
```

```
Function/Subroutine Documentation
   subroutine dgeql2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer INFO)
       DGEQL2 computes the QL factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   DGEQL2 computes a QL factorization of a real m by n matrix A: A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the n by n lower triangular matrix L;
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the m by n lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   orthogonal matrix Q as a product of elementary reflectors
   (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors
```

```
              Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

              H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
   A(1:m-k+i-1,n-k+i), and tau in TAU(i).
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqlf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           DGEQLF

Function/Subroutine Documentation
   subroutine dgeqlf (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DGEQLF

Purpose:
   DGEQLF computes a QL factorization of a real M-by-N matrix A: A = Q * L.

Parameters:
```

```
 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L;
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the M-by-N lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   orthogonal matrix Q as a product of elementary reflectors
   (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is the
   optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors
```

```
              Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

              H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
   A(1:m-k+i-1,n-k+i), and tau in TAU(i).
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqp3 (M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
           DGEQP3

Function/Subroutine Documentation
   subroutine dgeqp3 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) JPVT, double precision,
       dimension( * ) TAU, double precision, dimension( * ) WORK, integer
       LWORK, integer INFO)
       DGEQP3

Purpose:
   DGEQP3 computes a QR factorization with column pivoting of a
   matrix A:  A*P = Q*R  using Level 3 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the upper triangle of the array contains the
   min(M,N)-by-N upper trapezoidal matrix R; the elements below
   the diagonal, together with the array TAU, represent the
   orthogonal matrix Q as a product of min(M,N) elementary reflectors.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,M).
```

```
 JPVT
   JPVT is INTEGER array, dimension (N)
   On entry, if JPVT(J).ne.0, the J-th column of A is permuted
   to the front of A*P (a leading column); if JPVT(J)=0,
   the J-th column of A is a free column.
   On exit, if JPVT(J)=K, then the J-th column of A*P was the
   the K-th column of A.

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors.

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO=0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK >= 3*N+1.
   For optimal performance LWORK >= 2*N+( N+1 )*NB, where NB
   is the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0: successful exit.
   < 0: if INFO = -i, the i-th argument had an illegal value.

Further Details:
   The matrix Q is represented as a product of elementary reflectors

                Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

                H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real/complex vector
   with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in
   A(i+1:m,i), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqr2 (M, N, A, LDA, TAU, WORK, INFO)
           DGEQR2 computes the QR factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine dgeqr2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer INFO)
       DGEQR2 computes the QR factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   DGEQR2 computes a QR factorization of a real m by n matrix A: A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n); the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
```

```
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

               Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).

32.17.3 fortran code

From Elmroth and Gustavson [Elmr00]:

DGEQR2(m,n,A,τ)
do $j = 1, n$
  compute Householder transform $Q(j) = I - \tau uu^T$ such that
  $Q(j)^T A(j\colon m, j) = (x, 0)^T$ via a call to DLARFG
  if (j .LT. n) **then**
    apply$Q(j)^T$ to $A(j\colon m, j+1\colon n)$ from the left by calling DLARF
  endif
enddo

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqr2p (M, N, A, LDA, TAU, WORK, INFO)
           DGEQR2P computes the QR factorization of a general rectangular
           matrix with non-negative diagonal elements using an unblocked
           algorithm.

Function/Subroutine Documentation
   subroutine dgeqr2p (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer INFO)
       DGEQR2P computes the QR factorization of a general rectangular matrix
       with non-negative diagonal elements using an unblocked algorithm.

Purpose:
   DGEQR2 computes a QR factorization of a real m by n matrix A:
   A = Q * R. The diagonal entries of R are nonnegative.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n). The diagonal entries of R are
   nonnegative; the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (N)

 INFO
```

```
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

               Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqrf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           DGEQRF

Function/Subroutine Documentation
   subroutine dgeqrf (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DGEQRF

Purpose:
   DGEQRF computes a QR factorization of a real M-by-N matrix A: A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if m >= n); the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of min(m,n) elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

                Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

                H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).
```

32.19.3 fortran code

From Elmroth and Gustavson [Elmr00]:

DGEQRF(m,n,A,τ,$work$)
do $j = 1, n, nb$!nb is the block size
  $jb = \min(j - j + 1, nb)$
  call DGEQR2$[m - j + 1, jb, A(j, j), \tau(j)]$
  if $(j + jb$ .LE. $n)$ **then**
    compute $T(1\colon jb, 1\colon jn)$ in $work$ via a call to DLARFT
    compute $(I - YT^TY^T)A(j\colon m, j + jb\colon n)$ using $work$ and T
    via a call to DLARFB
  endif
enddo

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqrfp (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           DGEQRFP

Function/Subroutine Documentation
   subroutine dgeqrfp (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DGEQRFP

Purpose:
   DGEQRFP computes a QR factorization of a real M-by-N matrix A:
   A = Q * R. The diagonal entries of R are nonnegative.

Parameters:
```

```
 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if m >= n). The diagonal entries of R
   are nonnegative; the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of min(m,n) elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors
```

```
              Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

              H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).
```

Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqrt (M, N, NB, A, LDA, T, LDT, WORK, INFO)
           DGEQRT

Function/Subroutine Documentation
   subroutine dgeqrt (integer M, integer N, integer NB, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( ldt, *
       ) T, integer LDT, double precision, dimension( * ) WORK, integer INFO)
       DGEQRT

Purpose:
   DGEQRT computes a blocked QR factorization of a real M-by-N matrix A
   using the compact WY representation of Q.

Parameters:
```

```
 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NB
   NB is INTEGER
   The block size to be used in the blocked QR.  MIN(M,N) >= NB >= 1.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if M >= N); the elements below the diagonal
   are the columns of V.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is DOUBLE PRECISION array, dimension (LDT,MIN(M,N))
   The upper triangular block reflectors stored in compact form
   as a sequence of upper triangular blocks.  See below for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= NB.

 WORK
   WORK is DOUBLE PRECISION array, dimension (NB*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                         V = (  1       )
                             ( v1  1    )
                             ( v1 v2  1 )
                             ( v1 v2 v3 )
```

```
                              ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.

   Let K=MIN(M,N).  The number of blocks is B = ceiling(K/NB), where each
   block is of order NB except for the last block, which is of order
   IB = K - (B-1)*NB.  For each of the B blocks, a upper triangular block
   reflector factor is computed: T1, T2, ..., TB.  The NB-by-NB (and IB-by-IB
   for the last block) T's are stored in the NB-by-N matrix T as

                         T = (T1 T2 ... TB).

SYNOPSIS
   Functions/Subroutines
       subroutine dgeqrt2 (M, N, A, LDA, T, LDT, INFO)
           DGEQRT2 computes a QR factorization of a general real or complex
           matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   subroutine dgeqrt2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( ldt, * ) T, integer
       LDT, integer INFO)
       DGEQRT2 computes a QR factorization of a general real or complex matrix
       using the compact WY representation of Q.

Purpose:
   DGEQRT2 computes a QR factorization of a real M-by-N matrix A,
   using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the real M-by-N matrix A.  On exit, the elements on and
   above the diagonal contain the N-by-N upper triangular matrix R; the
```

```
   elements below the diagonal are the columns of V.  See below for
   further details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is DOUBLE PRECISION array, dimension (LDT,N)
   The N-by-N upper triangular factor of the block reflector.
   The elements on and above the diagonal contain the block
   reflector T; the elements below the diagonal are not used.
   See below for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                        V = (  1       )
                            ( v1  1    )
                            ( v1 v2  1 )
                            ( v1 v2 v3 )
                            ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
   block reflector H is then given by

                        H = I - V * T * V**T

   where V**T is the transpose of V.

SYNOPSIS
   Functions/Subroutines
       recursive subroutine dgeqrt3 (M, N, A, LDA, T, LDT, INFO)
           DGEQRT3 recursively computes a QR factorization of a general real
           or complex matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   recursive subroutine dgeqrt3 (integer M, integer N, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( ldt, *
       ) T, integer LDT, integer INFO)
       DGEQRT3 recursively computes a QR factorization of a general real or
       complex matrix using the compact WY representation of Q.

Purpose:
   DGEQRT3 recursively computes a QR factorization of a real M-by-N
   matrix A, using the compact WY representation of Q.

       Parameters:
           M

                     M is INTEGER
                     The number of rows of the matrix A.  M >= N.

           N

                     N is INTEGER
                     The number of columns of the matrix A.  N >= 0.

           A

                     A is DOUBLE PRECISION array, dimension (LDA,N)
                     On entry, the real M-by-N matrix A.  On exit, the elements on and
                     above the diagonal contain the N-by-N upper triangular matrix R; the
                     elements below the diagonal are the columns of V.  See below for
                     further details.

           LDA

                     LDA is INTEGER
                     The leading dimension of the array A.  LDA >= max(1,M).

           T

                     T is DOUBLE PRECISION array, dimension (LDT,N)
```

```
                The N-by-N upper triangular factor of the block reflector.
                The elements on and above the diagonal contain the block
                reflector T; the elements below the diagonal are not used.
                See below for further details.

        LDT

                LDT is INTEGER
                The leading dimension of the array T.  LDT >= max(1,N).

        INFO

                INFO is INTEGER
                = 0: successful exit
                < 0: if INFO = -i, the i-th argument had an illegal value

    Author:
        Univ. of Tennessee

        Univ. of California Berkeley

        Univ. of Colorado Denver

        NAG Ltd.

    Date:
        September 2012

    Further Details:

          The matrix V stores the elementary reflectors H(i) in the i-th column
          below the diagonal. For example, if M=5 and N=3, the matrix V is

                       V = (  1       )
                           ( v1  1    )
                           ( v1 v2  1 )
                           ( v1 v2 v3 )
                           ( v1 v2 v3 )

          where the vi's represent the vectors which define H(i), which are returned
          in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
          block reflector H is then given by

                       H = I - V * T * V**T

          where V**T is the transpose of V.

          For details of the algorithm, see Elmroth and Gustavson (cited above).

SYNOPSIS
   Functions/Subroutines
       subroutine dgerfs (TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, IWORK, INFO)
           DGERFS

Function/Subroutine Documentation
   subroutine dgerfs (character TRANS, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV,
       double precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( ldx, * ) X, integer LDX, double precision, dimension( * )
       FERR, double precision, dimension( * ) BERR, double precision,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       DGERFS

Purpose:
   DGERFS improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates for
   the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The original N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by DGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from DGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
```

```
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is DOUBLE PRECISION array, dimension (3*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.
```

       dimension( * ) IWORK, integer INFO)
       DGERFSX

Purpose:
   DGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
```

```
  provides maximum componentwise error bound if possible.  See
  comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
  error bounds.

  The original system of linear equations may have been equilibrated
  before calling this routine, as described by arguments EQUED, R
  and C below. In this case, the solution and error bounds returned
  are for the original unequilibrated system.

  Some optional parameters are bundled in the PARAMS array.  These
  settings determine how refinement is performed, but often the
  defaults are acceptable.  If the defaults are acceptable, users
  can pass NPARAMS = 0 which prevents the source code from accessing
  the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The original N-by-N matrix A.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by DGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from DGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.
  If R is accessed, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.
  If C is accessed, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
```

```
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                    max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
```

```
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * dlamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * dlamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*A, where S scales each row by a power of the
           radix so all absolute row sums of Z are approximately 1.

See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                    abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                          abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
```

```
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * dlamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * dlamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*(A*diag(x)), where x is the solution for the
           current right-hand side and S scales each row of
           A*diag(x) by a power of the radix so all absolute row
           sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension (NPARAMS)
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
```

```
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
     componentwise error is not requested (PARAMS(3) = 0.0) then
     the Jth right-hand side is the first with a normwise error
     bound that is not guaranteed (the smallest J such
     that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
     the Jth right-hand side is the first with either a normwise or
     componentwise error bound that is not guaranteed (the smallest
     J such that either ERR_BNDS_NORM(J,1) = 0.0 or
     ERR_BNDS_COMP(J,1) = 0.0). See the definition of
     ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
     about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine dgerq2 (M, N, A, LDA, TAU, WORK, INFO)
           DGERQ2 computes the RQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine dgerq2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer INFO)
       DGERQ2 computes the RQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   DGERQ2 computes an RQ factorization of a real m by n matrix A: A = R * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, if m <= n, the upper triangle of the subarray
   A(1:m,n-m+1:n) contains the m by m upper triangular matrix R;
   if m >= n, the elements on and above the (m-n)-th subdiagonal
   contain the m by n upper trapezoidal matrix R; the remaining
   elements, with the array TAU, represent the orthogonal matrix
   Q as a product of elementary reflectors (see Further Details).

 LDA
```

```
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

               Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on exit in
   A(m-k+i,1:n-k+i-1), and tau in TAU(i).

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgerqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           DGERQF

Function/Subroutine Documentation
   subroutine dgerqf (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) TAU, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DGERQF

Purpose:
   DGERQF computes an RQ factorization of a real M-by-N matrix A: A = R * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m <= n, the upper triangle of the subarray
   A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R;
   if m >= n, the elements on and above the (m-n)-th subdiagonal
   contain the M-by-N upper trapezoidal matrix R;
   the remaining elements, with the array TAU, represent the
   orthogonal matrix Q as a product of min(m,n) elementary
   reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is DOUBLE PRECISION array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,M).
   For optimum performance LWORK >= M*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
   The matrix Q is represented as a product of elementary reflectors

               Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on exit in
   A(m-k+i,1:n-k+i-1), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgesvj (JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV,
           WORK, LWORK, INFO)
           DGESVJ

Function/Subroutine Documentation
   subroutine dgesvj (character*1 JOBA, character*1 JOBU, character*1 JOBV,
       integer M, integer N, double precision, dimension( lda, * ) A, integer
       LDA, double precision, dimension( n ) SVA, integer MV, double
       precision, dimension( ldv, * ) V, integer LDV, double precision,
       dimension( lwork ) WORK, integer LWORK, integer INFO)
       DGESVJ

Purpose:
   DGESVJ computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, where M >= N. The SVD of A is written as
                                     [++]   [xx]   [x0]   [xx]
             A = U * SIGMA * V^t,  [++] = [xx] * [ox] * [xx]
                                     [++]   [xx]
   where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal
   matrix, and V is an N-by-N orthogonal matrix. The diagonal elements
   of SIGMA are the singular values of A. The columns of U and V are the
   left and the right singular vectors of A, respectively.
   DGESVJ can sometimes compute tiny singular values and their singular
   vectors much more accurately than other SVD routines,
```

```
   see below under Further Details.

Parameters:

 JOBA
   JOBA is CHARACTER* 1
   Specifies the structure of A.
   = 'L': The input matrix A is lower triangular;
   = 'U': The input matrix A is upper triangular;
   = 'G': The input matrix A is general M-by-N matrix, M >= N.

 JOBU
   JOBU is CHARACTER*1
   Specifies whether to compute the left singular vectors
   (columns of U):
   = 'U': The left singular vectors corresponding to the nonzero
      singular values are computed and returned in the leading
      columns of A. See more details in the description of A.
      The default numerical orthogonality threshold is set to
      approximately TOL=CTOL*EPS, CTOL=DSQRT(M), EPS=DLAMCH('E').
   = 'C': Analogous to JOBU='U', except that user can control the
      level of numerical orthogonality of the computed left
      singular vectors. TOL can be set to TOL = CTOL*EPS, where
      CTOL is given on input in the array WORK.
      No CTOL smaller than ONE is allowed. CTOL greater
      than 1 / EPS is meaningless. The option 'C'
      can be used if M*EPS is satisfactory orthogonality
      of the computed left singular vectors, so CTOL=M could
      save few sweeps of Jacobi rotations.
      See the descriptions of A and WORK(1).
   = 'N': The matrix U is not computed. However, see the description of A.

 JOBV
   JOBV is CHARACTER*1
   Specifies whether to compute the right singular vectors, that
   is, the matrix V:
   = 'V' : the matrix V is computed and returned in the array V
   = 'A' : the Jacobi rotations are applied to the MV-by-N
      array V. In other words, the right singular vector
      matrix V is not computed explicitly, instead it is
      applied to an MV-by-N matrix initially stored in the first MV rows of V.
   = 'N' : the matrix V is not computed and the array V is not referenced

 M
   M is INTEGER
   The number of rows of the input matrix A. 1/DLAMCH('E') > M >= 0.

 N
   N is INTEGER
   The number of columns of the input matrix A.
```

```
  M >= N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit :
  If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C' :
    If INFO .EQ. 0 :
       RANKA orthonormal columns of U are returned in the
       leading RANKA columns of the array A. Here RANKA <= N
       is the number of computed singular values of A that are
       above the underflow threshold DLAMCH('S'). The singular
       vectors corresponding to underflowed or zero singular
       values are not computed. The value of RANKA is returned
       in the array WORK as RANKA=NINT(WORK(2)). Also see the
       descriptions of SVA and WORK. The computed columns of U
       are mutually numerically orthogonal up to approximately
       TOL=DSQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'),
       see the description of JOBU.
    If INFO .GT. 0 :
       the procedure DGESVJ did not converge in the given number
       of iterations (sweeps). In that case, the computed
       columns of U may not be orthogonal up to TOL. The output
       U (stored in A), SIGMA (given by the computed singular
       values in SVA(1:N)) and V is still a decomposition of the
       input matrix A in the sense that the residual
       ||A-SCALE*U*SIGMA*V^T||_2 / ||A||_2 is small.

  If JOBU .EQ. 'N' :
    If INFO .EQ. 0 :
       Note that the left singular vectors are 'for free' in the
       one-sided Jacobi SVD algorithm. However, if only the
       singular values are needed, the level of numerical
       orthogonality of U is not an issue and iterations are
       stopped when the columns of the iterated matrix are
       numerically orthogonal up to approximately M*EPS. Thus,
       on exit, A contains the columns of U scaled with the
       corresponding singular values.
    If INFO .GT. 0 :
       the procedure DGESVJ did not converge in the given number
       of iterations (sweeps).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is DOUBLE PRECISION array, dimension (N)
  On exit :
  If INFO .EQ. 0 :
```

```
     depending on the value SCALE = WORK(1), we have:
     If SCALE .EQ. ONE :
        SVA(1:N) contains the computed singular values of A.
        During the computation SVA contains the Euclidean column
        norms of the iterated matrices in the array A.
     If SCALE .NE. ONE :
        The singular values of A are SCALE*SVA(1:N), and this
        factored representation is due to the fact that some of the
        singular values of A might underflow or overflow.
  If INFO .GT. 0 :
     the procedure DGESVJ did not converge in the given number of
     iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV
  MV is INTEGER
  If JOBV .EQ. 'A', then the product of Jacobi rotations in DGESVJ
  is applied to the first MV rows of V. See the description of JOBV.

V
  V is DOUBLE PRECISION array, dimension (LDV,N)
  If JOBV = 'V', then V contains on exit the N-by-N matrix of
     the right singular vectors;
  If JOBV = 'A', then V contains the product of the computed right
     singular vector matrix and the initial matrix in
     the array V.
  If JOBV = 'N', then V is not referenced.

LDV
  LDV is INTEGER
  The leading dimension of the array V, LDV .GE. 1.
  If JOBV .EQ. 'V', then LDV .GE. max(1,N).
  If JOBV .EQ. 'A', then LDV .GE. max(1,MV) .

WORK
  WORK is DOUBLE PRECISION array, dimension max(4,M+N).
  On entry :
  If JOBU .EQ. 'C' :
  WORK(1) = CTOL, where CTOL defines the threshold for convergence.
     The process stops if all columns of A are mutually
     orthogonal up to CTOL*EPS, EPS=DLAMCH('E').
     It is required that CTOL >= ONE, i.e. it is not
     allowed to force the routine to obtain orthogonality below EPS.
  On exit :
     WORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N)
       are the computed singular values of A.
       (See description of SVA().)
     WORK(2) = NINT(WORK(2)) is the number of the computed nonzero
       singular values.
     WORK(3) = NINT(WORK(3)) is the number of the computed singular
       values that are larger than the underflow threshold.
```

```
      WORK(4) = NINT(WORK(4)) is the number of sweeps of Jacobi
        rotations needed for numerical convergence.
      WORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep.
        This is useful information in cases when DGESVJ did
        not converge, as it can be used to estimate whether
        the output is stil useful and for post festum analysis.
      WORK(6) = the largest absolute value over all sines of the
        Jacobi rotation angles in the last sweep. It can be
        useful for a post festum analysis.

 LWORK
   LWORK is INTEGER
   length of WORK, WORK >= MAX(6,M+N)

 INFO
   INFO is INTEGER
   = 0 : successful exit.
   < 0 : if INFO = -i, then the i-th argument had an illegal value
   > 0 : DGESVJ did not converge in the maximal allowed number (30)
         of sweeps. The output may still be useful. See the
         description of WORK.

Further Details:
   The orthogonal N-by-N matrix V is obtained as a product of Jacobi plane
   rotations. The rotations are implemented as fast scaled rotations of
   Anda and Park [1]. In the case of underflow of the Jacobi angle, a
   modified Jacobi transformation of Drmac [4] is used. Pivot strategy uses
   column interchanges of de Rijk [2]. The relative accuracy of the computed
   singular values and the accuracy of the computed singular vectors (in
   angle metric) is as guaranteed by the theory of Demmel and Veselic [3].
   The condition number that determines the accuracy in the full rank case
   is essentially min_{D=diag} kappa(A*D), where kappa(.) is the
   spectral condition number. The best performance of this Jacobi SVD
   procedure is achieved if used in an  accelerated version of Drmac and
   Veselic [5,6], and it is the kernel routine in the SIGMA library [7].
   Some tunning parameters (marked with [TP]) are available for the
   implementer.
   The computational range for the nonzero singular values is the  machine
   number interval ( UNDERFLOW , OVERFLOW ). In extreme cases, even
   denormalized singular values can be computed with the corresponding
   gradual loss of accurate digits.

                 IF( ir1.EQ.0 ) THEN
*
*        Column norms are periodically updated by explicit
*        norm computation.
*        Caveat:
*        Unfortunately, some BLAS implementations compute DNRM2(M,A(1,p),1)
*        as DSQRT(DDOT(M,A(1,p),1,A(1,p),1)), which may cause the result to
*        overflow for ||A(:,p)||_2 > DSQRT(overflow_threshold), and to
*        underflow for ||A(:,p)||_2 < DSQRT(underflow_threshold).
*        Hence, DNRM2 cannot be trusted, not even in the case when
*        the true norm is far from the under(over)flow boundaries.
*        If properly implemented DNRM2 is available, the IF-THEN-ELSE
*        below should read "AAPP = DNRM2( M, A(1,p), 1 ) * WORK(p)".

SYNOPSIS
   Functions/Subroutines
       subroutine dgetf2 (M, N, A, LDA, IPIV, INFO)
           DGETF2 computes the LU factorization of a general m-by-n matrix
           using partial pivoting with row interchanges (unblocked algorithm).

Function/Subroutine Documentation
```

```
   subroutine dgetf2 (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       DGETF2 computes the LU factorization of a general m-by-n matrix using
       partial pivoting with row interchanges (unblocked algorithm).

Purpose:
   DGETF2 computes an LU factorization of a general m-by-n matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
      A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 2 BLAS version of the algorithm.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the m by n matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, U(k,k) is exactly zero. The factorization
      has been completed, but the factor U is exactly
      singular, and division by zero will occur if it is used
      to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgetrf (M, N, A, LDA, IPIV, INFO)
           DGETRF

Function/Subroutine Documentation
   subroutine dgetrf (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       DGETRF

Purpose:
   DGETRF computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
      A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 3 BLAS version of the algorithm.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M-by-N matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
      has been completed, but the factor U is exactly
      singular, and division by zero will occur if it is used
      to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       recursive subroutine dgetrf2 (M, N, A, LDA, IPIV, INFO)
           DGETRF2

Function/Subroutine Documentation
   recursive subroutine dgetrf2 (integer M, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       integer INFO)
       DGETRF2

Purpose:
   DGETRF2 computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
      A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

           [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
       A = [ -----|----- ]  with n1 = min(m,n)
           [  A21 | A22  ]       n2 = n-n1

                                           [ A11 ]
   The subroutine calls itself to factor [ --- ],
                                           [ A12 ]
                   [ A12 ]
   do the swaps on [ --- ], solve A12, update A22,
                   [ A22 ]

   then calls itself to factor A22 and do the swaps on A21.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
```

```
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the M-by-N matrix to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U; the unit diagonal elements of L are not stored.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.
```

       subroutine dgetri (N, A, LDA, IPIV, WORK, LWORK, INFO)
           DGETRI

Function/Subroutine Documentation
   subroutine dgetri (integer N, double precision, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, double precision, dimension(
       * ) WORK, integer LWORK, integer INFO)
       DGETRI

Purpose:
   DGETRI computes the inverse of a matrix using the LU factorization
   computed by DGETRF.

   This method inverts U and then computes inv(A) by solving the system
   inv(A)*L = inv(U) for inv(A).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the factors L and U from the factorization
   A = P*L*U as computed by DGETRF.
   On exit, if INFO = 0, the inverse of the original matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from DGETRF; for 1<=i<=N, row i of the
   matrix was interchanged with row IPIV(i).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
   On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

 LWORK
```

```
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimal performance LWORK >= N*NB, where NB is
  the optimal blocksize returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero; the matrix is
     singular and its inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine dgetrs (TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
          DGETRS

Function/Subroutine Documentation
   subroutine dgetrs (character TRANS, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, integer
       INFO)
       DGETRS

Purpose:
   DGETRS solves a system of linear equations
      A * X = B  or  A**T * X = B
   with a general N-by-N matrix A using the LU factorization computed
   by DGETRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B  (No transpose)
   = 'T':  A**T* X = B  (Transpose)
   = 'C':  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The factors L and U from the factorization A = P*L*U
   as computed by DGETRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from DGETRF; for 1<=i<=N, row i of the
   matrix was interchanged with row IPIV(i).

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
```

```
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dhgeqz (JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT,
           ALPHAR, ALPHAI, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, INFO)
           DHGEQZ

Function/Subroutine Documentation
   subroutine dhgeqz (character JOB, character COMPQ, character COMPZ, integer
       N, integer ILO, integer IHI, double precision, dimension( ldh, * ) H,
       integer LDH, double precision, dimension( ldt, * ) T, integer LDT,
       double precision, dimension( * ) ALPHAR, double precision, dimension( *
       ) ALPHAI, double precision, dimension( * ) BETA, double precision,
       dimension( ldq, * ) Q, integer LDQ, double precision, dimension( ldz, *
       ) Z, integer LDZ, double precision, dimension( * ) WORK, integer LWORK,
       integer INFO)
       DHGEQZ

Purpose:
   DHGEQZ computes the eigenvalues of a real matrix pair (H,T),
   where H is an upper Hessenberg matrix and T is upper triangular,
   using the double-shift QZ method.
   Matrix pairs of this type are produced by the reduction to
   generalized upper Hessenberg form of a real matrix pair (A,B):

   A = Q1*H*Z1**T,  B = Q1*T*Z1**T,
```

```
   as computed by DGGHRD.

   If JOB='S', then the Hessenberg-triangular pair (H,T) is
   also reduced to generalized Schur form,

   H = Q*S*Z**T,  T = Q*P*Z**T,

   where Q and Z are orthogonal matrices, P is an upper triangular
   matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2
   diagonal blocks.

   The 1-by-1 blocks correspond to real eigenvalues of the matrix pair
   (H,T) and the 2-by-2 blocks correspond to complex conjugate pairs of
   eigenvalues.

   Additionally, the 2-by-2 upper triangular diagonal blocks of P
   corresponding to 2-by-2 blocks of S are reduced to positive diagonal
   form, i.e., if S(j+1,j) is non-zero, then P(j+1,j) = P(j,j+1) = 0,
   P(j,j) > 0, and P(j+1,j+1) > 0.

   Optionally, the orthogonal matrix Q from the generalized Schur
   factorization may be postmultiplied into an input matrix Q1, and the
   orthogonal matrix Z may be postmultiplied into an input matrix Z1.
   If Q1 and Z1 are the orthogonal matrices from DGGHRD that reduced
   the matrix pair (A,B) to generalized upper Hessenberg form, then the
   output matrices Q1*Q and Z1*Z are the orthogonal factors from the
   generalized Schur factorization of (A,B):

   A = (Q1*Q)*S*(Z1*Z)**T,  B = (Q1*Q)*P*(Z1*Z)**T.

   To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently,
   of (A,B)) are computed as a pair of values (alpha,beta), where alpha is
   complex and beta real.
   If beta is nonzero, lambda = alpha / beta is an eigenvalue of the
   generalized nonsymmetric eigenvalue problem (GNEP)
        A*x = lambda*B*x
   and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the
   alternate form of the GNEP
        mu*A*y = B*y.
   Real eigenvalues can be read directly from the generalized Schur
   form:
        alpha = S(i,i), beta = P(i,i).

Parameters:

 JOB
   JOB is CHARACTER*1
   = 'E': Compute eigenvalues only;
   = 'S': Compute eigenvalues and the Schur form.
```

```
COMPQ
  COMPQ is CHARACTER*1
  = 'N': Left Schur vectors (Q) are not computed;
  = 'I': Q is initialized to the unit matrix and the matrix Q
     of left Schur vectors of (H,T) is returned;
  = 'V': Q must contain an orthogonal matrix Q1 on entry and
     the product Q1*Q is returned.

COMPZ
  COMPZ is CHARACTER*1
  = 'N': Right Schur vectors (Z) are not computed;
  = 'I': Z is initialized to the unit matrix and the matrix Z
         of right Schur vectors of (H,T) is returned;
  = 'V': Z must contain an orthogonal matrix Z1 on entry and
         the product Z1*Z is returned.

N
  N is INTEGER
  The order of the matrices H, T, Q, and Z.  N >= 0.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI mark the rows and columns of H which are in
  Hessenberg form.  It is assumed that A is already upper
  triangular in rows and columns 1:ILO-1 and IHI+1:N.
  If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H
  H is DOUBLE PRECISION array, dimension (LDH, N)
  On entry, the N-by-N upper Hessenberg matrix H.
  On exit, if JOB = 'S', H contains the upper quasi-triangular
  matrix S from the generalized Schur factorization.
  If JOB = 'E', the diagonal blocks of H match those of S, but
  the rest of H is unspecified.

LDH
  LDH is INTEGER
  The leading dimension of the array H.  LDH >= max( 1, N ).

T
  T is DOUBLE PRECISION array, dimension (LDT, N)
  On entry, the N-by-N upper triangular matrix T.
  On exit, if JOB = 'S', T contains the upper triangular
  matrix P from the generalized Schur factorization;
  2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S
  are reduced to positive diagonal form, i.e., if H(j+1,j) is
```

```
  non-zero, then T(j+1,j) = T(j,j+1) = 0, T(j,j) > 0, and
  T(j+1,j+1) > 0.
  If JOB = 'E', the diagonal blocks of T match those of P, but
  the rest of T is unspecified.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= max( 1, N ).

ALPHAR
  ALPHAR is DOUBLE PRECISION array, dimension (N)
  The real parts of each scalar alpha defining an eigenvalue of GNEP.

ALPHAI
  ALPHAI is DOUBLE PRECISION array, dimension (N)
  The imaginary parts of each scalar alpha defining an
  eigenvalue of GNEP.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) = -ALPHAI(j).

BETA
  BETA is DOUBLE PRECISION array, dimension (N)
  The scalars beta that define the eigenvalues of GNEP.
  Together, the quantities alpha = (ALPHAR(j),ALPHAI(j)) and
  beta = BETA(j) represent the j-th eigenvalue of the matrix
  pair (A,B), in one of the forms lambda = alpha/beta or
  mu = beta/alpha.  Since either lambda or mu may overflow,
  they should not, in general, be computed.

Q
  Q is DOUBLE PRECISION array, dimension (LDQ, N)
  On entry, if COMPZ = 'V', the orthogonal matrix Q1 used in
  the reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the orthogonal matrix of left Schur
  vectors of (H,T), and if COMPZ = 'V', the orthogonal matrix
  of left Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.  LDQ >= 1.
  If COMPQ='V' or 'I', then LDQ >= N.

Z
  Z is DOUBLE PRECISION array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the orthogonal matrix Z1 used in
  the reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the orthogonal matrix of
  right Schur vectors of (H,T), and if COMPZ = 'V', the
```

```
  orthogonal matrix of right Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

 LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1.
  If COMPZ='V' or 'I', then LDZ >= N.

 WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

 LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1,...,N: the QZ iteration did not converge.  (H,T) is not
             in Schur form, but ALPHAR(i), ALPHAI(i), and
             BETA(i), i=INFO+1,...,N should be correct.
  = N+1,...,2*N: the shift calculation failed.  (H,T) is not
             in Schur form, but ALPHAR(i), ALPHAI(i), and
             BETA(i), i=INFO-N+1,...,N should be correct.

Further Details:

 Iteration counters:

 JITER  -- counts iterations.
 IITER  -- counts iterations run since ILAST was last
           changed.  This is therefore reset only when a 1-by-1 or
           2-by-2 block deflates off the bottom.

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dla_geamv (TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
           INCY)
           DLA_GEAMV computes a matrix-vector product using a general matrix
           to calculate error bounds.

Function/Subroutine Documentation
   subroutine dla_geamv (integer TRANS, integer M, integer N, double precision
       ALPHA, double precision, dimension( lda, * ) A, integer LDA, double
       precision, dimension( * ) X, integer INCX, double precision BETA,
       double precision, dimension( * ) Y, integer INCY)
       DLA_GEAMV computes a matrix-vector product using a general matrix to
       calculate error bounds.

Purpose:
```

```
  DLA_GEAMV  performs one of the matrix-vector operations

            y := alpha*abs(A)*abs(x) + beta*abs(y),
       or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

  where alpha and beta are scalars, x and y are vectors and A is an
  m by n matrix.

  This function is primarily used in calculating error bounds.
  To protect against underflow during evaluation, components in
  the resulting vector are perturbed away from zero by (N+1)
  times the underflow threshold.  To prevent unnecessarily large
  errors for block-structure embedded in general matrices,
  "symbolically" zero components are not perturbed.  A zero
  entry is considered "symbolic" if all multiplications involved
  in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
  TRANS is INTEGER
  On entry, TRANS specifies the operation to be performed as
  follows:

  BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
  BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
  BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

  Unchanged on exit.

 M
  M is INTEGER
  On entry, M specifies the number of rows of the matrix A.
  M must be at least zero.
  Unchanged on exit.

 N
  N is INTEGER
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

 ALPHA
  ALPHA is DOUBLE PRECISION
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

 A
  A is DOUBLE PRECISION array of DIMENSION ( LDA, n )
  Before entry, the leading m by n part of the array A must
```

```
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least
  max( 1, m ).
  Unchanged on exit.

X
  X is DOUBLE PRECISION array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the
  vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is DOUBLE PRECISION
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is DOUBLE PRECISION
  Array of DIMENSION at least
     ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
     ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       double precision function dla_gercond (TRANS, N, A, LDA, AF, LDAF,
           IPIV, CMODE, C, INFO, WORK, IWORK)
           DLA_GERCOND estimates the Skeel condition number for a general
           matrix.

Function/Subroutine Documentation
   double precision function dla_gercond (character TRANS, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV,
       integer CMODE, double precision, dimension( * ) C, integer INFO, double
       precision, dimension( * ) WORK, integer, dimension( * ) IWORK)
       DLA_GERCOND estimates the Skeel condition number for a general matrix.

Purpose:
   DLA_GERCOND estimates the Skeel condition number of op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)
```

```
N
  N is INTEGER
  The number of linear equations, i.e., the order of the
  matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by DGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by DGETRF; row i of the matrix was interchanged
  with row IPIV(i).

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N).
  Workspace.

IWORK
```

```
IWORK is INTEGER array, dimension (N).
Workspace.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dla_gerfsx_extended (PREC_TYPE, TRANS_TYPE, N, NRHS, A, LDA,
           AF, LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS,
           ERRS_N, ERRS_C, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
           DZ_UB, IGNORE_CWISE, INFO)
           DLA_GERFSX_EXTENDED improves the computed solution to a system of
           linear equations for general matrices by performing extra-precise
           iterative refinement and provides error bounds and backward error
           estimates for the solution.

       RTHRESH, double precision DZ_UB, logical IGNORE_CWISE, integer INFO)
       DLA_GERFSX_EXTENDED improves the computed solution to a system of
       linear equations for general matrices by performing extra-precise
       iterative refinement and provides error bounds and backward error
       estimates for the solution.

Purpose:
   DLA_GERFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by DGERFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERRS_N
   and ERRS_C for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERRS_N and ERRS_C.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 TRANS_TYPE
   TRANS_TYPE is INTEGER
   Specifies the transposition operation on A.
   The value is defined by ILATRANS(T) where T is a CHARACTER and
   T    = 'N':  No transpose
        = 'T':  Transpose
        = 'C':  Conjugate transpose

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by DGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by DGETRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
```

```
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is DOUBLE PRECISION array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERRS_N and ERRS_C).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERRS_N
  ERRS_N is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
