           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                    max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERRS_N(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_N(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').
```

```
  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.
  See Lapack Working Note 165 for further details and extra cautions.

ERRS_C
  ERRS_C is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERRS_C is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERRS_C(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_C(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
```

```
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * slamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*(A*diag(x)), where x is the solution for the
      current right-hand side and S scales each row of
      A*diag(x) by a power of the radix so all absolute row
      sums of Z are approximately 1.

   This subroutine is only responsible for setting the second field above.
   See Lapack Working Note 165 for further details and extra cautions.

RES
   RES is DOUBLE PRECISION array, dimension (N)
   Workspace to hold the intermediate residual.

AYB
   AYB is DOUBLE PRECISION array, dimension (N)
   Workspace. This can be the same workspace passed for Y_TAIL.

DY
   DY is DOUBLE PRECISION array, dimension (N)
   Workspace to hold the intermediate solution.

Y_TAIL
   Y_TAIL is DOUBLE PRECISION array, dimension (N)
   Workspace to hold the trailing bits of the intermediate solution.

RCOND
   RCOND is DOUBLE PRECISION
   Reciprocal scaled condition number.  This is an estimate of the
   reciprocal Skeel condition number of the matrix A after
   equilibration (if done).  If this is less than the machine
   precision (in particular, if it is zero), the matrix is singular
   to working precision.  Note that the error may still be small even
   if this number is very small and the matrix appears ill-conditioned.

ITHRESH
   ITHRESH is INTEGER
   The maximum number of residual computations allowed for
   refinement. The default is 10. For 'aggressive' set to 100 to
   permit convergence using approximate factorizations or
   factorizations other than LU. If the factorization uses a
   technique other than Gaussian elimination, the guarantees in
   ERRS_N and ERRS_C may no longer be trustworthy.
```

```
 RTHRESH
   RTHRESH is DOUBLE PRECISION
   Determines when to stop refinement if the error estimate stops
   decreasing. Refinement will stop when the next solution no longer
   satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
   the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
   default value is 0.5. For 'aggressive' set to 0.9 to permit
   convergence on extremely ill-conditioned matrices. See LAWN 165
   for more details.

 DZ_UB
   DZ_UB is DOUBLE PRECISION
   Determines when to start considering componentwise convergence.
   Componentwise convergence is only considered after each component
   of the solution Y is stable, which we definte as the relative
   change in each component being less than DZ_UB. The default value
   is 0.25, requiring the first bit to be stable. See LAWN 165 for
   more details.

 IGNORE_CWISE
   IGNORE_CWISE is LOGICAL
   If .TRUE. then ignore componentwise convergence. Default value
   is .FALSE..

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   < 0:  if INFO = -i, the ith argument to DGETRS had an illegal value
```

==========================================================================
Man Page Details
==========================================================================

SYNOPSIS
   Functions/Subroutines
       double precision function dla_gerpvgrw (N, NCOLS, A, LDA, AF, LDAF)
           DLA_GERPVGRW

Function/Subroutine Documentation
   double precision function dla_gerpvgrw (integer N, integer NCOLS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF)
       DLA_GERPVGRW

Purpose:
   DLA_GERPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by DGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).
```

SYNOPSIS
   Functions/Subroutines
       subroutine dtgevc (SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL,
           VR, LDVR, MM, M, WORK, INFO)
           DTGEVC

Function/Subroutine Documentation
   subroutine dtgevc (character SIDE, character HOWMNY, logical, dimension( *
       ) SELECT, integer N, double precision, dimension( lds, * ) S, integer
       LDS, double precision, dimension( ldp, * ) P, integer LDP, double
       precision, dimension( ldvl, * ) VL, integer LDVL, double precision,
       dimension( ldvr, * ) VR, integer LDVR, integer MM, integer M, double
       precision, dimension( * ) WORK, integer INFO)
       DTGEVC

Purpose:
   DTGEVC computes some or all of the right and/or left eigenvectors of
   a pair of real matrices (S,P), where S is a quasi-triangular matrix
   and P is upper triangular.  Matrix pairs of this type are produced by
   the generalized Schur factorization of a matrix pair (A,B):

   A = Q*S*Z**T,  B = Q*P*Z**T

   as computed by DGGHRD + DHGEQZ.
```

```
   The right eigenvector x and the left eigenvector y of (S,P)
   corresponding to an eigenvalue w are defined by:

   S*x = w*P*x,  (y**H)*S = w*(y**H)*P,

   where y**H denotes the conjugate tranpose of y.
   The eigenvalues are not input to this routine, but are computed
   directly from the diagonal blocks of S and P.

   This routine returns the matrices X and/or Y of right and left
   eigenvectors of (S,P), or the products Z*X and/or Q*Y,
   where Z and Q are input matrices.
   If Q and Z are the orthogonal factors from the generalized Schur
   factorization of a matrix pair (A,B), then Z*X and Q*Y
   are the matrices of right and left eigenvectors of (A,B).

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'R': compute right eigenvectors only;
   = 'L': compute left eigenvectors only;
   = 'B': compute both right and left eigenvectors.

 HOWMNY
   HOWMNY is CHARACTER*1
   = 'A': compute all right and/or left eigenvectors;
   = 'B': compute all right and/or left eigenvectors,
      backtransformed by the matrices in VR and/or VL;
   = 'S': compute selected right and/or left eigenvectors,
      specified by the logical array SELECT.

 SELECT
   SELECT is LOGICAL array, dimension (N)
   If HOWMNY='S', SELECT specifies the eigenvectors to be
   computed.  If w(j) is a real eigenvalue, the corresponding
   real eigenvector is computed if SELECT(j) is .TRUE..
   If w(j) and w(j+1) are the real and imaginary parts of a
   complex eigenvalue, the corresponding complex eigenvector
   is computed if either SELECT(j) or SELECT(j+1) is .TRUE.,
   and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is
   set to .FALSE..
   Not referenced if HOWMNY = 'A' or 'B'.

 N
   N is INTEGER
   The order of the matrices S and P.  N >= 0.

 S
   S is DOUBLE PRECISION array, dimension (LDS,N)
```

```
  The upper quasi-triangular matrix S from a generalized Schur
  factorization, as computed by DHGEQZ.

LDS
  LDS is INTEGER
  The leading dimension of array S.  LDS >= max(1,N).

P
  P is DOUBLE PRECISION array, dimension (LDP,N)
  The upper triangular matrix P from a generalized Schur
  factorization, as computed by DHGEQZ.
  2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks
  of S must be in positive diagonal form.

LDP
  LDP is INTEGER
  The leading dimension of array P.  LDP >= max(1,N).

VL
  VL is DOUBLE PRECISION array, dimension (LDVL,MM)
  On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must
  contain an N-by-N matrix Q (usually the orthogonal matrix Q
  of left Schur vectors returned by DHGEQZ).
  On exit, if SIDE = 'L' or 'B', VL contains:
  if HOWMNY = 'A', the matrix Y of left eigenvectors of (S,P);
  if HOWMNY = 'B', the matrix Q*Y;
  if HOWMNY = 'S', the left eigenvectors of (S,P) specified by
                   SELECT, stored consecutively in the columns of
                   VL, in the same order as their eigenvalues.

  A complex eigenvector corresponding to a complex eigenvalue
  is stored in two consecutive columns, the first holding the
  real part, and the second the imaginary part.

  Not referenced if SIDE = 'R'.

LDVL
  LDVL is INTEGER
  The leading dimension of array VL.  LDVL >= 1, and if
  SIDE = 'L' or 'B', LDVL >= N.

VR
  VR is DOUBLE PRECISION array, dimension (LDVR,MM)
  On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must
  contain an N-by-N matrix Z (usually the orthogonal matrix Z
  of right Schur vectors returned by DHGEQZ).

  On exit, if SIDE = 'R' or 'B', VR contains:
  if HOWMNY = 'A', the matrix X of right eigenvectors of (S,P);
  if HOWMNY = 'B' or 'b', the matrix Z*X;
```

```
   if HOWMNY = 'S' or 's', the right eigenvectors of (S,P)
                specified by SELECT, stored consecutively in the
                columns of VR, in the same order as their eigenvalues.

   A complex eigenvector corresponding to a complex eigenvalue
   is stored in two consecutive columns, the first holding the
   real part and the second the imaginary part.

   Not referenced if SIDE = 'L'.

 LDVR
   LDVR is INTEGER
   The leading dimension of the array VR.  LDVR >= 1, and if
   SIDE = 'R' or 'B', LDVR >= N.

 MM
   MM is INTEGER
   The number of columns in the arrays VL and/or VR. MM >= M.

 M
   M is INTEGER
   The number of columns in the arrays VL and/or VR actually
   used to store the eigenvectors.  If HOWMNY = 'A' or 'B', M
   is set to N.  Each selected real eigenvector occupies one
   column and each selected complex eigenvector occupies two columns.

 WORK
   WORK is DOUBLE PRECISION array, dimension (6*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

Further Details:

   Allocation of workspace:
   ---------- -- ---------

   WORK( j ) = 1-norm of j-th column of A, above the diagonal
   WORK( N+j ) = 1-norm of j-th column of B, above the diagonal
   WORK( 2*N+1:3*N ) = real part of eigenvector
   WORK( 3*N+1:4*N ) = imaginary part of eigenvector
   WORK( 4*N+1:5*N ) = real part of back-transformed eigenvector
   WORK( 5*N+1:6*N ) = imaginary part of back-transformed eigenvector

   Rowwise vs. columnwise solution methods:
   ------- --  ---------- -------- -------
```

```
Finding a generalized eigenvector consists basically of solving the
singular triangular system

(A - w B) x = 0     (for right) or:   (A - w B)**H y = 0  (for left)

Consider finding the i-th right eigenvector (assume all eigenvalues
are real). The equation to be solved is:
         n                   i
    0 = sum  C(j,k) v(k)  = sum  C(j,k) v(k)     for j = i,. . .,1
        k=j                 k=j

where  C = (A - w B)  (The components v(i+1:n) are 0.)

The "rowwise" method is:

(1)  v(i) := 1
     for j = i-1,. . .,1:
                                  i
     (2) compute  s = - sum C(j,k) v(k)   and
                       k=j+1

 (3) v(j) := s / C(j,j)

Step 2 is sometimes called the "dot product" step, since it is an
inner product between the j-th row and the portion of the eigenvector
that has been computed so far.

The "columnwise" method consists basically in doing the sums
for all the rows in parallel.  As each v(j) is computed, the
contribution of v(j) times the j-th column of C is added to the
partial sums.  Since FORTRAN arrays are stored columnwise, this has
the advantage that at each step, the elements of C that are accessed
are adjacent to one another, whereas with the rowwise method, the
elements accessed at a step are spaced LDS (and LDP) words apart.

When finding left eigenvectors, the matrix in question is the
transpose of the one in storage, so the rowwise method then
actually accesses columns of A and B at each step, and so is the
preferred method.

SYNOPSIS
   Functions/Subroutines
       subroutine dtgexc (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
           IFST, ILST, WORK, LWORK, INFO)
           DTGEXC

Function/Subroutine Documentation
   subroutine dtgexc (logical WANTQ, logical WANTZ, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( ldq, *
       ) Q, integer LDQ, double precision, dimension( ldz, * ) Z, integer LDZ,
       integer IFST, integer ILST, double precision, dimension( * ) WORK,
       integer LWORK, integer INFO)
       DTGEXC

Purpose:
   DTGEXC reorders the generalized real Schur decomposition of a real
   matrix pair (A,B) using an orthogonal equivalence transformation

     (A, B) = Q * (A, B) * Z**T,

   so that the diagonal block of (A, B) with row index IFST is moved
   to row ILST.

   (A, B) must be in generalized real Schur canonical form (as returned
   by DGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2
   diagonal blocks. B is upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.

     Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
```

```
     Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the matrix A in generalized real Schur canonical form.
   On exit, the updated matrix A, again in generalized
   real Schur canonical form.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is DOUBLE PRECISION array, dimension (LDB,N)
   On entry, the matrix B in generalized real Schur canonical form (A,B).
   On exit, the updated matrix B, again in generalized
   real Schur canonical form (A,B).

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,N).

 Q
   Q is DOUBLE PRECISION array, dimension (LDQ,N)
   On entry, if WANTQ = .TRUE., the orthogonal matrix Q.
   On exit, the updated matrix Q.
   If WANTQ = .FALSE., Q is not referenced.

 LDQ
   LDQ is INTEGER
   The leading dimension of the array Q. LDQ >= 1.
   If WANTQ = .TRUE., LDQ >= N.

 Z
```

```
  Z is DOUBLE PRECISION array, dimension (LDZ,N)
  On entry, if WANTZ = .TRUE., the orthogonal matrix Z.
  On exit, the updated matrix Z.
  If WANTZ = .FALSE., Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z. LDZ >= 1.
  If WANTZ = .TRUE., LDZ >= N.

IFST
  IFST is INTEGER

ILST
  ILST is INTEGER
  Specify the reordering of the diagonal blocks of (A, B).
  The block with row index IFST is moved to row ILST, by a
  sequence of swapping between adjacent blocks.
  On exit, if IFST pointed on entry to the second row of
  a 2-by-2 block, it is changed to point to the first row;
  ILST always points to the first row of the block in its
  final position (which may differ from its input value by
  +1 or -1). 1 <= IFST, ILST <= N.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= 1 when N <= 1, otherwise LWORK >= 4*N + 16.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  =0:  successful exit.
  <0:  if INFO = -i, the i-th argument had an illegal value.
  =1:  The transformed matrix pair (A, B) would be too far
       from generalized Schur form; the problem is ill-
       conditioned. (A, B) may have been partially reordered,
       and ILST points to the first row of the current
       position of the block being moved.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgesvj (JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV,
           CWORK, LWORK, RWORK, LRWORK, INFO)
           ZGESVJ

Function/Subroutine Documentation
   subroutine zgesvj (character*1 JOBA, character*1 JOBU, character*1 JOBV,
       integer M, integer N, complex*16, dimension( lda, * ) A, integer LDA,
       double precision, dimension( n ) SVA, integer MV, complex*16,
       dimension( ldv, * ) V, integer LDV, complex*16, dimension( lwork )
       CWORK, integer LWORK, double precision, dimension( lrwork ) RWORK,
       integer LRWORK, integer INFO)
       ZGESVJ

Purpose:
   ZGESVJ computes the singular value decomposition (SVD) of a complex
   M-by-N matrix A, where M >= N. The SVD of A is written as
                                [++]   [xx]   [x0]   [xx]
           A = U * SIGMA * V^*,  [++] = [xx] * [ox] * [xx]
                                [++]   [xx]
   where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal
   matrix, and V is an N-by-N unitary matrix. The diagonal elements
   of SIGMA are the singular values of A. The columns of U and V are the
   left and the right singular vectors of A, respectively.

Parameters:

 JOBA
   JOBA is CHARACTER* 1
   Specifies the structure of A.
   = 'L': The input matrix A is lower triangular;
   = 'U': The input matrix A is upper triangular;
   = 'G': The input matrix A is general M-by-N matrix, M >= N.

 JOBU
   JOBU is CHARACTER*1
   Specifies whether to compute the left singular vectors
   (columns of U):
   = 'U': The left singular vectors corresponding to the nonzero
          singular values are computed and returned in the leading
          columns of A. See more details in the description of A.
          The default numerical orthogonality threshold is set to
          approximately TOL=CTOL*EPS, CTOL=DSQRT(M), EPS=DLAMCH('E').
   = 'C': Analogous to JOBU='U', except that user can control the
          level of numerical orthogonality of the computed left
          singular vectors. TOL can be set to TOL = CTOL*EPS, where
          CTOL is given on input in the array WORK.
          No CTOL smaller than ONE is allowed. CTOL greater
```

```
         than 1 / EPS is meaningless. The option 'C'
         can be used if M*EPS is satisfactory orthogonality
         of the computed left singular vectors, so CTOL=M could
         save few sweeps of Jacobi rotations.
         See the descriptions of A and WORK(1).
  = 'N': The matrix U is not computed. However, see the
         description of A.

JOBV
  JOBV is CHARACTER*1
  Specifies whether to compute the right singular vectors, that
  is, the matrix V:
  = 'V' : the matrix V is computed and returned in the array V
  = 'A' : the Jacobi rotations are applied to the MV-by-N
          array V. In other words, the right singular vector
          matrix V is not computed explicitly, instead it is
          applied to an MV-by-N matrix initially stored in the
          first MV rows of V.
  = 'N' : the matrix V is not computed and the array V is not referenced

M
  M is INTEGER
  The number of rows of the input matrix A. 1/DLAMCH('E') > M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.
  M >= N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C':
    If INFO .EQ. 0 :
      RANKA orthonormal columns of U are returned in the
      leading RANKA columns of the array A. Here RANKA <= N
      is the number of computed singular values of A that are
      above the underflow threshold DLAMCH('S'). The singular
      vectors corresponding to underflowed or zero singular
      values are not computed. The value of RANKA is returned
      in the array RWORK as RANKA=NINT(RWORK(2)). Also see the
      descriptions of SVA and RWORK. The computed columns of U
      are mutually numerically orthogonal up to approximately
      TOL=SQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'),
      see the description of JOBU.
    If INFO .GT. 0,
      the procedure ZGESVJ did not converge in the given number
      of iterations (sweeps). In that case, the computed
      columns of U may not be orthogonal up to TOL. The output
```

```
      U (stored in A), SIGMA (given by the computed singular
      values in SVA(1:N)) and V is still a decomposition of the
      input matrix A in the sense that the residual
      || A - SCALE * U * SIGMA * V^* ||_2 / ||A||_2 is small.
  If JOBU .EQ. 'N':
    If INFO .EQ. 0 :
      Note that the left singular vectors are 'for free' in the
      one-sided Jacobi SVD algorithm. However, if only the
      singular values are needed, the level of numerical
      orthogonality of U is not an issue and iterations are
      stopped when the columns of the iterated matrix are
      numerically orthogonal up to approximately M*EPS. Thus,
      on exit, A contains the columns of U scaled with the
      corresponding singular values.
    If INFO .GT. 0 :
      the procedure ZGESVJ did not converge in the given number
      of iterations (sweeps).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is DOUBLE PRECISION array, dimension (N)
  On exit,
  If INFO .EQ. 0 :
    depending on the value SCALE = RWORK(1), we have:
      If SCALE .EQ. ONE:
        SVA(1:N) contains the computed singular values of A.
        During the computation SVA contains the Euclidean column
        norms of the iterated matrices in the array A.
      If SCALE .NE. ONE:
        The singular values of A are SCALE*SVA(1:N), and this
        factored representation is due to the fact that some of the
        singular values of A might underflow or overflow.

  If INFO .GT. 0 :
    the procedure ZGESVJ did not converge in the given number of
    iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV
  MV is INTEGER
  If JOBV .EQ. 'A', then the product of Jacobi rotations in ZGESVJ
  is applied to the first MV rows of V. See the description of JOBV.

V
  V is COMPLEX*16 array, dimension (LDV,N)
  If JOBV = 'V', then V contains on exit the N-by-N matrix of
     the right singular vectors;
  If JOBV = 'A', then V contains the product of the computed right
```

```
     singular vector matrix and the initial matrix in the array V.
  If JOBV = 'N', then V is not referenced.

LDV
  LDV is INTEGER
  The leading dimension of the array V, LDV .GE. 1.
  If JOBV .EQ. 'V', then LDV .GE. max(1,N).
  If JOBV .EQ. 'A', then LDV .GE. max(1,MV) .

CWORK
  CWORK is COMPLEX*16 array, dimension M+N.
  Used as work space.

LWORK
  LWORK is INTEGER.
  Length of CWORK, LWORK >= M+N.

RWORK
  RWORK is DOUBLE PRECISION array, dimension max(6,M+N).
  On entry,
  If JOBU .EQ. 'C' :
    RWORK(1) = CTOL, where CTOL defines the threshold for convergence.
      The process stops if all columns of A are mutually
      orthogonal up to CTOL*EPS, EPS=DLAMCH('E').
      It is required that CTOL >= ONE, i.e. it is not
      allowed to force the routine to obtain orthogonality below EPSILON.
  On exit,
    RWORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N)
      are the computed singular values of A. (See description of SVA().)
    RWORK(2) = NINT(RWORK(2)) is the number of the computed nonzero
      singular values.
    RWORK(3) = NINT(RWORK(3)) is the number of the computed singular
      values that are larger than the underflow threshold.
    RWORK(4) = NINT(RWORK(4)) is the number of sweeps of Jacobi
      rotations needed for numerical convergence.
    RWORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep.
      This is useful information in cases when ZGESVJ did
      not converge, as it can be used to estimate whether
      the output is stil useful and for post festum analysis.
    RWORK(6) = the largest absolute value over all sines of the
      Jacobi rotation angles in the last sweep. It can be
      useful for a post festum analysis.

LRWORK
  LRWORK is INTEGER
  Length of RWORK, LRWORK >= MAX(6,N).

INFO
  INFO is INTEGER
  = 0 : successful exit.
```

```
   < 0 : if INFO = -i, then the i-th argument had an illegal value
   > 0 : ZGESVJ did not converge in the maximal allowed number
         (NSWEEP=30) of sweeps. The output may still be useful.
         See the description of RWORK.

Further Details:

   The orthogonal N-by-N matrix V is obtained as a product of Jacobi plane
   rotations. In the case of underflow of the tangent of the Jacobi angle, a
   modified Jacobi transformation of Drmac [3] is used. Pivot strategy uses
   column interchanges of de Rijk [1]. The relative accuracy of the computed
   singular values and the accuracy of the computed singular vectors (in
   angle metric) is as guaranteed by the theory of Demmel and Veselic [2].
   The condition number that determines the accuracy in the full rank case
   is essentially min_{D=diag} kappa(A*D), where kappa(.) is the
   spectral condition number. The best performance of this Jacobi SVD
   procedure is achieved if used in an  accelerated version of Drmac and
   Veselic [4,5], and it is the kernel routine in the SIGMA library [6].
   Some tunning parameters (marked with [TP]) are available for the
   implementer.
   The computational range for the nonzero singular values is the  machine
   number interval ( UNDERFLOW , OVERFLOW ). In extreme cases, even
   denormalized singular values can be computed with the corresponding
   gradual loss of accurate digits.

         Column norms are periodically updated by explicit
         norm computation.
*[!]     Caveat:
*        Unfortunately, some BLAS implementations compute DZNRM2(M,A(1,p),1)
*        as SQRT(S=CDOTC(M,A(1,p),1,A(1,p),1)), which may cause the result to
*        overflow for ||A(:,p)||_2 > SQRT(overflow_threshold), and to
*        underflow for ||A(:,p)||_2 < SQRT(underflow_threshold).
*        Hence, DZNRM2 cannot be trusted, not even in the case when
*        the true norm is far from the under(over)flow boundaries.
*        If properly implemented SCNRM2 is available, the IF-THEN-ELSE-END IF
*        below should be replaced with "AAPP = DZNRM2( M, A(1,p), 1 )".

SYNOPSIS
   Functions/Subroutines
       subroutine sgebak (JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
           SGEBAK

Function/Subroutine Documentation
   subroutine sgebak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, real, dimension( * ) SCALE, integer M, real, dimension(
       ldv, * ) V, integer LDV, integer INFO)
       SGEBAK

Purpose:
   SGEBAK forms the right or left eigenvectors of a real general matrix
   by backward transformation on the computed eigenvectors of the
   balanced matrix output by SGEBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N', do nothing, return immediately;
   = 'P', do backward transformation for permutation only;
   = 'S', do backward transformation for scaling only;
   = 'B', do backward transformations for both permutation and scaling.
   JOB must be the same as the argument JOB supplied to SGEBAL.

 SIDE
   SIDE is CHARACTER*1
   = 'R':  V contains right eigenvectors;
   = 'L':  V contains left eigenvectors.

 N
   N is INTEGER
   The number of rows of the matrix V.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   The integers ILO and IHI determined by SGEBAL.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 SCALE
```

```
  SCALE is REAL array, dimension (N)
  Details of the permutation and scaling factors, as returned by SGEBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is REAL array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by SHSEIN or STREVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the array V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgebal (JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
           SGEBAL

Function/Subroutine Documentation
   subroutine sgebal (character JOB, integer N, real, dimension( lda, * ) A,
       integer LDA, integer ILO, integer IHI, real, dimension( * ) SCALE,
       integer INFO)
       SGEBAL

Purpose:
   SGEBAL balances a general real matrix A.  This involves, first,
   permuting A by a similarity transformation to isolate eigenvalues
   in the first 1 to ILO-1 and last IHI+1 to N elements on the
   diagonal; and second, applying a diagonal similarity transformation
   to rows and columns ILO to IHI to make the rows and columns as
   close in norm as possible.  Both steps are optional.

   Balancing may reduce the 1-norm of the matrix, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A:
   = 'N':  none:  simply set ILO = 1, IHI = N, SCALE(I) = 1.0
      for i = 1,...,N;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the input matrix A.
   On exit,  A is overwritten by the balanced matrix.
   If JOB = 'N', A is not referenced.
   See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 ILO
```

```
  ILO is INTEGER

 IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

 SCALE
  SCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied to
  A.  If P(j) is the index of the row and column interchanged
  with row and column j and D(j) is the scaling factor
  applied to row and column j, then
  SCALE(j) = P(j)    for j = 1,...,ILO-1
           = D(j)    for j = ILO,...,IHI
           = P(j)    for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

 INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

  The permutations consist of row and column interchanges which put
  the matrix in the form

                         ( T1   X   Y  )
               P A P = (  0   B   Z  )
                         (  0   0   T2 )

  where T1 and T2 are upper triangular matrices whose eigenvalues lie
  along the diagonal.  The column indices ILO and IHI mark the starting
  and ending columns of the submatrix B. Balancing consists of applying
  a diagonal similarity transformation inv(D) * B * D to make the
  1-norms of each row of B and its corresponding column nearly equal.
  The output matrix is

               ( T1     X*D          Y    )
               (  0  inv(D)*B*D  inv(D)*Z ).
               (  0      0           T2   )

  Information about the permutations P and the diagonal matrix D is
  returned in the vector SCALE.

  This subroutine is based on the EISPACK routine BALANC.

SYNOPSIS
   Functions/Subroutines
       subroutine sgebd2 (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
           SGEBD2 reduces a general matrix to bidiagonal form using an
           unblocked algorithm.

Function/Subroutine Documentation
   subroutine sgebd2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) D, real, dimension( * ) E, real,
       dimension( * ) TAUQ, real, dimension( * ) TAUP, real, dimension( * )
       WORK, integer INFO)
       SGEBD2 reduces a general matrix to bidiagonal form using an unblocked
       algorithm.

Purpose:
   SGEBD2 reduces a real general m by n matrix A to upper or lower
   bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the m by n general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
     overwritten with the upper bidiagonal matrix B; the
     elements below the diagonal, with the array TAUQ, represent
     the orthogonal matrix Q as a product of elementary
     reflectors, and the elements above the first superdiagonal,
     with the array TAUP, represent the orthogonal matrix P as
     a product of elementary reflectors;
   if m < n, the diagonal and the first subdiagonal are
     overwritten with the lower bidiagonal matrix B; the
```

```
     elements below the first subdiagonal, with the array TAUQ,
     represent the orthogonal matrix Q as a product of
     elementary reflectors, and the elements above the diagonal,
     with the array TAUP, represent the orthogonal matrix P as
     a product of elementary reflectors.
     See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 D
   D is REAL array, dimension (min(M,N))
   The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

 E
   E is REAL array, dimension (min(M,N)-1)
   The off-diagonal elements of the bidiagonal matrix B:
   if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
   if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

 TAUQ
   TAUQ is REAL array dimension (min(M,N))
   The scalar factors of the elementary reflectors which
   represent the orthogonal matrix Q. See Further Details.

 TAUP
   TAUP is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors which
   represent the orthogonal matrix P. See Further Details.

 WORK
   WORK is REAL array, dimension (max(M,N))

 INFO
   INFO is INTEGER
   = 0: successful exit.
   < 0: if INFO = -i, the i-th argument had an illegal value.

Further Details:
   The matrices Q and P are represented as products of elementary
   reflectors:

   If m >= n,

       Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

   Each H(i) and G(i) has the form:

       H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T
```

```
where tauq and taup are real scalars, and v and u are real vectors;
v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i);
u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

If m < n,

     Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

     H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

where tauq and taup are real scalars, and v and u are real vectors;
v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

          m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

            (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
            (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
            (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
            (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
            (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
            (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal elements of B, vi
denotes an element of the vector defining H(i), and ui an element of
the vector defining G(i).

SYNOPSIS
   Functions/Subroutines
       subroutine sgebrd (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
           SGEBRD

Function/Subroutine Documentation
   subroutine sgebrd (integer M, integer N, real, dimension( lda, * ) A,
```

```
      integer LDA, real, dimension( * ) D, real, dimension( * ) E, real,
      dimension( * ) TAUQ, real, dimension( * ) TAUP, real, dimension( * )
      WORK, integer LWORK, integer INFO)
      SGEBRD

Purpose:
   SGEBRD reduces a general real M-by-N matrix A to upper or lower
   bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
      overwritten with the upper bidiagonal matrix B; the
      elements below the diagonal, with the array TAUQ, represent
      the orthogonal matrix Q as a product of elementary
      reflectors, and the elements above the first superdiagonal,
      with the array TAUP, represent the orthogonal matrix P as
      a product of elementary reflectors;
   if m < n, the diagonal and the first subdiagonal are
      overwritten with the lower bidiagonal matrix B; the
      elements below the first subdiagonal, with the array TAUQ,
      represent the orthogonal matrix Q as a product of
      elementary reflectors, and the elements above the diagonal,
      with the array TAUP, represent the orthogonal matrix P as
      a product of elementary reflectors.
   See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 D
   D is REAL array, dimension (min(M,N))
   The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

 E
```

```
  E is REAL array, dimension (min(M,N)-1)
  The off-diagonal elements of the bidiagonal matrix B:
  if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
  if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ
  TAUQ is REAL array dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the orthogonal matrix Q. See Further Details.

TAUP
  TAUP is REAL array, dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the orthogonal matrix P. See Further Details.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,M,N).
  For optimum performance LWORK >= (M+N)*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

  The matrices Q and P are represented as products of elementary
  reflectors:

  If m >= n,

     Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

  Each H(i) and G(i) has the form:

     H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

  where tauq and taup are real scalars, and v and u are real vectors;
  v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i);
```

```
u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

If m < n,

    Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

    H(i) = I - tauq * v * v**T  and G(i) = I - taup * u * u**T

where tauq and taup are real scalars, and v and u are real vectors;
v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

          m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

            (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
            (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
            (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
            (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
            (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
            (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal elements of B, vi
denotes an element of the vector defining H(i), and ui an element of
the vector defining G(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgecon (NORM, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
           SGECON

Function/Subroutine Documentation
   subroutine sgecon (character NORM, integer N, real, dimension( lda, * ) A,
       integer LDA, real ANORM, real RCOND, real, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
```

```
      SGECON

Purpose:
   SGECON estimates the reciprocal of the condition number of a general
   real matrix A, in either the 1-norm or the infinity-norm, using
   the LU factorization computed by SGETRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
      RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The factors L and U from the factorization A = P*L*U
   as computed by SGETRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 ANORM
   ANORM is REAL
   If NORM = '1' or 'O', the 1-norm of the original matrix A.
   If NORM = 'I', the infinity-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(norm(A) * norm(inv(A))).

 WORK
   WORK is REAL array, dimension (4*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

SYNOPSIS
   Functions/Subroutines
       subroutine sgeequ (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           SGEEQU

Function/Subroutine Documentation
   subroutine sgeequ (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) R, real, dimension( * ) C, real
       ROWCND, real COLCND, real AMAX, integer INFO)
       SGEEQU

Purpose:
   SGEEQU computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
```

```
  elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

  R(i) and C(j) are restricted to be between SMLNUM = smallest safe
  number and BIGNUM = largest safe number.  Use of these scaling
  factors is not guaranteed to reduce the condition number of A but
  works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The M-by-N matrix whose equilibration factors are to be computed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 R
   R is REAL array, dimension (M)
   If INFO = 0 or INFO > M, R contains the row scale factors for A.

 C
   C is REAL array, dimension (N)
   If INFO = 0,  C contains the column scale factors for A.

 ROWCND
   ROWCND is REAL
   If INFO = 0 or INFO > M, ROWCND contains the ratio of the
   smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
   AMAX is neither too large nor too small, it is not worth scaling by R.

 COLCND
   COLCND is REAL
   If INFO = 0, COLCND contains the ratio of the smallest
   C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

 AMAX
   AMAX is REAL
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix should be scaled.

 INFO
```

```
INFO is INTEGER
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value
> 0:  if INFO = i,  and i is
  <= M:  the i-th row of A is exactly zero

SYNOPSIS
   Functions/Subroutines
       subroutine sgeequb (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           SGEEQUB

Function/Subroutine Documentation
   subroutine sgeequb (integer M, integer N, real, dimension( lda, * ) A,
```

```
      integer LDA, real, dimension( * ) R, real, dimension( * ) C, real
      ROWCND, real COLCND, real AMAX, integer INFO)
      SGEEQUB

Purpose:
   SGEEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from SGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The M-by-N matrix whose equilibration factors are to be computed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 R
   R is REAL array, dimension (M)
   If INFO = 0 or INFO > M, R contains the row scale factors for A.

 C
   C is REAL array, dimension (N)
   If INFO = 0,  C contains the column scale factors for A.

 ROWCND
```

```
  ROWCND is REAL
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is REAL
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i,  and i is
    <= M:  the i-th row of A is exactly zero
    >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgehd2 (N, ILO, IHI, A, LDA, TAU, WORK, INFO)
           SGEHD2 reduces a general square matrix to upper Hessenberg form
           using an unblocked algorithm.
```

```
Function/Subroutine Documentation
   subroutine sgehd2 (integer N, integer ILO, integer IHI, real, dimension(
       lda, * ) A, integer LDA, real, dimension( * ) TAU, real, dimension( * )
       WORK, integer INFO)
       SGEHD2 reduces a general square matrix to upper Hessenberg form using
       an unblocked algorithm.

Purpose:
   SGEHD2 reduces a real general matrix A to upper Hessenberg form H by
   an orthogonal similarity transformation:  Q**T * A * Q = H .

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to SGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= max(1,N).

 A
   A is REAL array, dimension (LDA,N)
   On entry, the n by n general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the orthogonal matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is REAL array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (N)

 INFO
```

```
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

 Further Details:

  The matrix Q is represented as a product of (ihi-ilo) elementary
  reflectors

     Q = H(ilo) H(ilo+1) . . . H(ihi-1).

  Each H(i) has the form

     H(i) = I - tau * v * v**T

  where tau is a real scalar, and v is a real vector with
  v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
  exit in A(i+2:ihi,i), and tau in TAU(i).

  The contents of A are illustrated by the following example, with
  n = 7, ilo = 2 and ihi = 6:

            on entry,                        on exit,

            ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
            (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
            (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
            (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
            (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
            (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
            (                       a )    (                          a )

  where a denotes an element of the original matrix A, h denotes a
  modified element of the upper Hessenberg matrix H, and vi denotes an
  element of the vector defining H(i).

SYNOPSIS
   Functions/Subroutines
       subroutine sgehrd (N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
           SGEHRD

Function/Subroutine Documentation
   subroutine sgehrd (integer N, integer ILO, integer IHI, real, dimension(
       lda, * ) A, integer LDA, real, dimension( * ) TAU, real, dimension( * )
       WORK, integer LWORK, integer INFO)
       SGEHRD

Purpose:
   SGEHRD reduces a real general matrix A to upper Hessenberg form H by
   an orthogonal similarity transformation:  Q**T * A * Q = H .

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER
```

```
 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to SGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the orthogonal matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is REAL array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further
   Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to
   zero.

 WORK
   WORK is REAL array, dimension (LWORK)
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of the array WORK.  LWORK >= max(1,N).
   For good performance, LWORK should generally be larger.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrix Q is represented as a product of (ihi-ilo) elementary
```

```
reflectors

   Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Each H(i) has the form

   H(i) = I - tau * v * v**T

where tau is a real scalar, and v is a real vector with
v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with
n = 7, ilo = 2 and ihi = 6:

          on entry,                        on exit,

          ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
          (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
          (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
          (                       a )    (                          a )

where a denotes an element of the original matrix A, h denotes a
modified element of the upper Hessenberg matrix H, and vi denotes an
element of the vector defining H(i).

This file is a slight modification of LAPACK-3.0's DGEHRD
subroutine incorporating improvements proposed by Quintana-Orti and
Van de Geijn (2006). (See DLAHR2.)

Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgelq2 (M, N, A, LDA, TAU, WORK, INFO)
           SGELQ2 computes the LQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine sgelq2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer INFO)
       SGELQ2 computes the LQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   SGELQ2 computes an LQ factorization of a real m by n matrix A: A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
```

```
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and below the diagonal of the array
   contain the m by min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on exit in A(i,i+1:n),
   and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine sgelqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           SGELQF

Function/Subroutine Documentation
   subroutine sgelqf (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
       SGELQF

Purpose:
   SGELQF computes an LQ factorization of a real M-by-N matrix A: A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and below the diagonal of the array
   contain the m-by-min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
```

```
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,M).
   For optimum performance LWORK >= M*NB, where NB is the
   optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on exit in A(i,i+1:n),
   and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine sgemqrt (SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC,
           WORK, INFO)
           SGEMQRT

Function/Subroutine Documentation
   subroutine sgemqrt (character SIDE, character TRANS, integer M, integer N,
       integer K, integer NB, real, dimension( ldv, * ) V, integer LDV, real,
       dimension( ldt, * ) T, integer LDT, real, dimension( ldc, * ) C,
       integer LDC, real, dimension( * ) WORK, integer INFO)
       SGEMQRT

Purpose:
   SGEMQRT overwrites the general real M-by-N matrix C with

                              SIDE = 'L'     SIDE = 'R'
            TRANS = 'N':      Q C            C Q
            TRANS = 'T':   Q**T C            C Q**T

   where Q is a real orthogonal matrix defined as the product of K
   elementary reflectors:

                  Q = H(1) H(2) . . . H(K) = I - V T V**T

   generated using the compact WY representation as returned by SGEQRT.

   Q is of order M if SIDE = 'L' and of order N  if SIDE = 'R'.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'L': apply Q or Q**T from the Left;
   = 'R': apply Q or Q**T from the Right.

 TRANS
   TRANS is CHARACTER*1
   = 'N':  No transpose, apply Q;
   = 'T':  Transpose, apply Q**T.

 M
   M is INTEGER
   The number of rows of the matrix C. M >= 0.
```

```
N
  N is INTEGER
  The number of columns of the matrix C. N >= 0.

K
  K is INTEGER
  The number of elementary reflectors whose product defines the matrix Q.
  If SIDE = 'L', M >= K >= 0;
                   if SIDE = 'R', N >= K >= 0.

NB
  NB is INTEGER
  The block size used for the storage of T.  K >= NB >= 1.
  This must be the same value of NB used to generate T in CGEQRT.

V
  V is REAL array, dimension (LDV,K)
  The i-th column must contain the vector which defines the
  elementary reflector H(i), for i = 1,2,...,k, as returned by
  CGEQRT in the first K columns of its array argument A.

LDV
  LDV is INTEGER
  The leading dimension of the array V.
  If SIDE = 'L', LDA >= max(1,M);
  if SIDE = 'R', LDA >= max(1,N).

T
  T is REAL array, dimension (LDT,K)
  The upper triangular factors of the block reflectors
  as returned by CGEQRT, stored as a NB-by-N matrix.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= NB.

C
  C is REAL array, dimension (LDC,N)
  On entry, the M-by-N matrix C.
  On exit, C is overwritten by Q C, Q**T C, C Q**T or C Q.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M).

WORK
  WORK is REAL array. The dimension of WORK is
  N*NB if SIDE = 'L', or  M*NB if SIDE = 'R'.

INFO
```

```
INFO is INTEGER
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value
```

==================================================================
Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgeql2 (M, N, A, LDA, TAU, WORK, INFO)
           SGEQL2 computes the QL factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine sgeql2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer INFO)
       SGEQL2 computes the QL factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   SGEQL2 computes a QL factorization of a real m by n matrix A: A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the n by n lower triangular matrix L;
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the m by n lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   orthogonal matrix Q as a product of elementary reflectors
   (see Further Details).
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
   A(1:m-k+i-1,n-k+i), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqlf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           SGEQLF

Function/Subroutine Documentation
   subroutine sgeqlf (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
       SGEQLF

Purpose:
   SGEQLF computes a QL factorization of a real M-by-N matrix A: A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L;
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the M-by-N lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   orthogonal matrix Q as a product of elementary reflectors
   (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
```

```
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is the
   optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
   A(1:m-k+i-1,n-k+i), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqp3 (M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
           SGEQP3

Function/Subroutine Documentation
   subroutine sgeqp3 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) JPVT, real, dimension( * ) TAU,
       real, dimension( * ) WORK, integer LWORK, integer INFO)
       SGEQP3

Purpose:
   SGEQP3 computes a QR factorization with column pivoting of a
   matrix A:  A*P = Q*R  using Level 3 BLAS.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A. M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the upper triangle of the array contains the
  min(M,N)-by-N upper trapezoidal matrix R; the elements below
  the diagonal, together with the array TAU, represent the
  orthogonal matrix Q as a product of min(M,N) elementary reflectors.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

JPVT
  JPVT is INTEGER array, dimension (N)
  On entry, if JPVT(J).ne.0, the J-th column of A is permuted
  to the front of A*P (a leading column); if JPVT(J)=0,
  the J-th column of A is a free column.
  On exit, if JPVT(J)=K, then the J-th column of A*P was the
  the K-th column of A.

TAU
  TAU is REAL array, dimension (min(M,N))
  The scalar factors of the elementary reflectors.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= 3*N+1.
  For optimal performance LWORK >= 2*N+( N+1 )*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
```

```
   = 0: successful exit.
   < 0: if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real/complex vector
   with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in
   A(i+1:m,i), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqr2 (M, N, A, LDA, TAU, WORK, INFO)
           SGEQR2 computes the QR factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine sgeqr2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer INFO)
       SGEQR2 computes the QR factorization of a general rectangular matrix
       using an unblocked algorithm.
```

```
Purpose:
   SGEQR2 computes a QR factorization of a real m by n matrix A: A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n); the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
```

and tau in TAU(i).

Man Page Details
==========================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqr2p (M, N, A, LDA, TAU, WORK, INFO)
           SGEQR2P computes the QR factorization of a general rectangular
           matrix with non-negative diagonal elements using an unblocked
           algorithm.

Function/Subroutine Documentation
   subroutine sgeqr2p (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer INFO)
       SGEQR2P computes the QR factorization of a general rectangular matrix
       with non-negative diagonal elements using an unblocked algorithm.

Purpose:
   SGEQR2P computes a QR factorization of a real m by n matrix A:
   A = Q * R. The diagonal entries of R are nonnegative.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n). The diagonal entries of R
   are nonnegative; the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of elementary reflectors (see Further Details).
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqrf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           SGEQRF

Function/Subroutine Documentation
   subroutine sgeqrf (integer M, integer N, real, dimension( lda, * ) A,
```

```
      integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
      integer LWORK, integer INFO)
      SGEQRF

Purpose:
   SGEQRF computes a QR factorization of a real M-by-N matrix A: A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if m >= n); the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of min(m,n) elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
```

```
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqrfp (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           SGEQRFP

Function/Subroutine Documentation
   subroutine sgeqrfp (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
```

```
       SGEQRFP

Purpose:
   SGEQRFP computes a QR factorization of a real M-by-N matrix A:
   A = Q * R. The diagonal entries of R are nonnegative.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if m >= n). The diagonal entries of R
   are nonnegative; the elements below the diagonal,
   with the array TAU, represent the orthogonal matrix Q as a
   product of min(m,n) elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
```

```
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

      Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqrt (M, N, NB, A, LDA, T, LDT, WORK, INFO)
           SGEQRT

Function/Subroutine Documentation
   subroutine sgeqrt (integer M, integer N, integer NB, real, dimension( lda,
       * ) A, integer LDA, real, dimension( ldt, * ) T, integer LDT, real,
       dimension( * ) WORK, integer INFO)
```

```
       SGEQRT

Purpose:
   SGEQRT computes a blocked QR factorization of a real M-by-N matrix A
   using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NB
   NB is INTEGER
   The block size to be used in the blocked QR.  MIN(M,N) >= NB >= 1.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if M >= N); the elements below the diagonal
   are the columns of V.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is REAL array, dimension (LDT,MIN(M,N))
   The upper triangular block reflectors stored in compact form
   as a sequence of upper triangular blocks.  See below
   for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= NB.

 WORK
   WORK is REAL array, dimension (NB*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

```
Further Details:

   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                        V = (  1       )
                            ( v1  1    )
                            ( v1 v2  1 )
                            ( v1 v2 v3 )
                            ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.

   Let K=MIN(M,N).  The number of blocks is B = ceiling(K/NB), where each
   block is of order NB except for the last block, which is of order
   IB = K - (B-1)*NB.  For each of the B blocks, a upper triangular block
   reflector factor is computed: T1, T2, ..., TB.  The NB-by-NB (and IB-by-IB
   for the last block) T's are stored in the NB-by-N matrix T as

                        T = (T1 T2 ... TB).
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgeqrt2 (M, N, A, LDA, T, LDT, INFO)
           SGEQRT2 computes a QR factorization of a general real or complex
           matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   subroutine sgeqrt2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( ldt, * ) T, integer LDT, integer INFO)
       SGEQRT2 computes a QR factorization of a general real or complex matrix
       using the compact WY representation of Q.

Purpose:
   SGEQRT2 computes a QR factorization of a real M-by-N matrix A,
   using the compact WY representation of Q.
```

```
Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the real M-by-N matrix A.  On exit, the elements on and
   above the diagonal contain the N-by-N upper triangular matrix R; the
   elements below the diagonal are the columns of V.  See below for
   further details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is REAL array, dimension (LDT,N)
   The N-by-N upper triangular factor of the block reflector.
   The elements on and above the diagonal contain the block
   reflector T; the elements below the diagonal are not used.
   See below for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                         V = (  1       )
                             ( v1  1    )
                             ( v1 v2  1 )
                             ( v1 v2 v3 )
                             ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
```

```
   block reflector H is then given by

                        H = I - V * T * V**T

   where V**T is the transpose of V.
```

==========================================================================

SYNOPSIS
   Functions/Subroutines
       recursive subroutine sgeqrt3 (M, N, A, LDA, T, LDT, INFO)
           SGEQRT3 recursively computes a QR factorization of a general real
           or complex matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   recursive subroutine sgeqrt3 (integer M, integer N, real, dimension( lda, *
       ) A, integer LDA, real, dimension( ldt, * ) T, integer LDT, integer
       INFO)
       SGEQRT3 recursively computes a QR factorization of a general real or
       complex matrix using the compact WY representation of Q.

Purpose:
   SGEQRT3 recursively computes a QR factorization of a real M-by-N
   matrix A, using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the real M-by-N matrix A.  On exit, the elements on and
```

```
  above the diagonal contain the N-by-N upper triangular matrix R; the
  elements below the diagonal are the columns of V.  See below for
  further details.

 LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

 T
  T is REAL array, dimension (LDT,N)
  The N-by-N upper triangular factor of the block reflector.
  The elements on and above the diagonal contain the block
  reflector T; the elements below the diagonal are not used.
  See below for further details.

 LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= max(1,N).

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

  The matrix V stores the elementary reflectors H(i) in the i-th column
  below the diagonal. For example, if M=5 and N=3, the matrix V is

                        V = (  1       )
                            ( v1  1    )
                            ( v1 v2  1 )
                            ( v1 v2 v3 )
                            ( v1 v2 v3 )

  where the vi's represent the vectors which define H(i), which are returned
  in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
  block reflector H is then given by

                        H = I - V * T * V**T

  where V**T is the transpose of V.

SYNOPSIS
   Functions/Subroutines
       subroutine sgerfs (TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, IWORK, INFO)
           SGERFS

Function/Subroutine Documentation
   subroutine sgerfs (character TRANS, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * ) AF,
       integer LDAF, integer, dimension( * ) IPIV, real, dimension( ldb, * )
       B, integer LDB, real, dimension( ldx, * ) X, integer LDX, real,
       dimension( * ) FERR, real, dimension( * ) BERR, real, dimension( * )
       WORK, integer, dimension( * ) IWORK, integer INFO)
       SGERFS

Purpose:
   SGERFS improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates for
   the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The original N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
AF
  AF is REAL array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by SGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from SGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (3*N)
```

```
 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

       ) IWORK, integer INFO)
       SGERFSX

Purpose:
   SGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.
```

```
Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).
   The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The original N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The factors L and U from the factorization A = P*L*U
   as computed by SGETRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
```

```
  The pivot indices from SGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.
  If R is accessed, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.
  If C is accessed, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
```

```
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
```

```
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.
```

```
NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be
              trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
  has been completed, but the factor U is exactly singular, so
```

```
   the solution and error bounds could not be computed. RCOND = 0
   is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine sgerq2 (M, N, A, LDA, TAU, WORK, INFO)
           SGERQ2 computes the RQ factorization of a general rectangular
           matrix using an unblocked algorithm.
```

```
Function/Subroutine Documentation
   subroutine sgerq2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer INFO)
       SGERQ2 computes the RQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   SGERQ2 computes an RQ factorization of a real m by n matrix A: A = R * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, if m <= n, the upper triangle of the subarray
   A(1:m,n-m+1:n) contains the m by m upper triangular matrix R;
   if m >= n, the elements on and above the (m-n)-th subdiagonal
   contain the m by n upper trapezoidal matrix R; the remaining
   elements, with the array TAU, represent the orthogonal matrix
   Q as a product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

 Further Details:

   The matrix Q is represented as a product of elementary reflectors
```

```
      Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on exit in
   A(m-k+i,1:n-k+i-1), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgerqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           SGERQF

Function/Subroutine Documentation
   subroutine sgerqf (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) TAU, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
       SGERQF

Purpose:
   SGERQF computes an RQ factorization of a real M-by-N matrix A: A = R * Q.

Parameters:
```

```
 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m <= n, the upper triangle of the subarray
   A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R;
   if m >= n, the elements on and above the (m-n)-th subdiagonal
   contain the M-by-N upper trapezoidal matrix R;
   the remaining elements, with the array TAU, represent the
   orthogonal matrix Q as a product of min(m,n) elementary
   reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,M).
   For optimum performance LWORK >= M*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:
```

```
The matrix Q is represented as a product of elementary reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - tau * v * v**T

where tau is a real scalar, and v is a real vector with
v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on exit in
A(m-k+i,1:n-k+i-1), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgesvj (JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV,
           WORK, LWORK, INFO)
           SGESVJ

Function/Subroutine Documentation
   subroutine sgesvj (character*1 JOBA, character*1 JOBU, character*1 JOBV,
       integer M, integer N, real, dimension( lda, * ) A, integer LDA, real,
       dimension( n ) SVA, integer MV, real, dimension( ldv, * ) V, integer
       LDV, real, dimension( lwork ) WORK, integer LWORK, integer INFO)
       SGESVJ

Purpose:
   SGESVJ computes the singular value decomposition (SVD) of a real
   M-by-N matrix A, where M >= N. The SVD of A is written as
                                    [++]   [xx]   [x0]   [xx]
             A = U * SIGMA * V^t,   [++] = [xx] * [ox] * [xx]
                                    [++]   [xx]
   where SIGMA is an N-by-N diagonal matrix, U is an M-by-N orthonormal
   matrix, and V is an N-by-N orthogonal matrix. The diagonal elements
   of SIGMA are the singular values of A. The columns of U and V are the
   left and the right singular vectors of A, respectively.
   SGESVJ can sometimes compute tiny singular values and their singular
   vectors much more accurately than other SVD routines,
   see below under Further Details.

Parameters:

 JOBA
   JOBA is CHARACTER* 1
```

```
  Specifies the structure of A.
  = 'L': The input matrix A is lower triangular;
  = 'U': The input matrix A is upper triangular;
  = 'G': The input matrix A is general M-by-N matrix, M >= N.

JOBU
  JOBU is CHARACTER*1
  Specifies whether to compute the left singular vectors
  (columns of U):
  = 'U': The left singular vectors corresponding to the nonzero
     singular values are computed and returned in the leading
     columns of A. See more details in the description of A.
     The default numerical orthogonality threshold is set to
     approximately TOL=CTOL*EPS, CTOL=SQRT(M), EPS=SLAMCH('E').
  = 'C': Analogous to JOBU='U', except that user can control the
     level of numerical orthogonality of the computed left
     singular vectors. TOL can be set to TOL = CTOL*EPS, where
     CTOL is given on input in the array WORK.
     No CTOL smaller than ONE is allowed. CTOL greater
     than 1 / EPS is meaningless. The option 'C'
     can be used if M*EPS is satisfactory orthogonality
     of the computed left singular vectors, so CTOL=M could
     save few sweeps of Jacobi rotations.
     See the descriptions of A and WORK(1).
  = 'N': The matrix U is not computed. However, see the description of A.

JOBV
  JOBV is CHARACTER*1
  Specifies whether to compute the right singular vectors, that
  is, the matrix V:
  = 'V' : the matrix V is computed and returned in the array V
  = 'A' : the Jacobi rotations are applied to the MV-by-N
     array V. In other words, the right singular vector
     matrix V is not computed explicitly; instead it is
     applied to an MV-by-N matrix initially stored in the first MV rows of V.
  = 'N' : the matrix V is not computed and the array V is not referenced

M
  M is INTEGER
  The number of rows of the input matrix A. 1/SLAMCH('E') > M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.
  M >= N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
```

```
  If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C':
    If INFO .EQ. 0 :
      RANKA orthonormal columns of U are returned in the
      leading RANKA columns of the array A. Here RANKA <= N
      is the number of computed singular values of A that are
      above the underflow threshold SLAMCH('S'). The singular
      vectors corresponding to underflowed or zero singular
      values are not computed. The value of RANKA is returned
      in the array WORK as RANKA=NINT(WORK(2)). Also see the
      descriptions of SVA and WORK. The computed columns of U
      are mutually numerically orthogonal up to approximately
      TOL=SQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'),
      see the description of JOBU.
    If INFO .GT. 0,
      the procedure SGESVJ did not converge in the given number
      of iterations (sweeps). In that case, the computed
      columns of U may not be orthogonal up to TOL. The output
      U (stored in A), SIGMA (given by the computed singular
      values in SVA(1:N)) and V is still a decomposition of the
      input matrix A in the sense that the residual
      ||A-SCALE*U*SIGMA*V^T||_2 / ||A||_2 is small.
  If JOBU .EQ. 'N':
    If INFO .EQ. 0 :
      Note that the left singular vectors are 'for free' in the
      one-sided Jacobi SVD algorithm. However, if only the
      singular values are needed, the level of numerical
      orthogonality of U is not an issue and iterations are
      stopped when the columns of the iterated matrix are
      numerically orthogonal up to approximately M*EPS. Thus,
      on exit, A contains the columns of U scaled with the
      corresponding singular values.
    If INFO .GT. 0 :
      the procedure SGESVJ did not converge in the given number
      of iterations (sweeps).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SVA
  SVA is REAL array, dimension (N)
  On exit,
  If INFO .EQ. 0 :
  depending on the value SCALE = WORK(1), we have:
    If SCALE .EQ. ONE:
      SVA(1:N) contains the computed singular values of A.
      During the computation SVA contains the Euclidean column
      norms of the iterated matrices in the array A.
    If SCALE .NE. ONE:
      The singular values of A are SCALE*SVA(1:N), and this
```

```
      factored representation is due to the fact that some of the
      singular values of A might underflow or overflow.

  If INFO .GT. 0 :
    the procedure SGESVJ did not converge in the given number of
    iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV
  MV is INTEGER
  If JOBV .EQ. 'A', then the product of Jacobi rotations in SGESVJ
  is applied to the first MV rows of V. See the description of JOBV.

V
  V is REAL array, dimension (LDV,N)
  If JOBV = 'V', then V contains on exit the N-by-N matrix of
     the right singular vectors;
  If JOBV = 'A', then V contains the product of the computed right
     singular vector matrix and the initial matrix in the array V.
  If JOBV = 'N', then V is not referenced.

LDV
  LDV is INTEGER
  The leading dimension of the array V, LDV .GE. 1.
  If JOBV .EQ. 'V', then LDV .GE. max(1,N).
  If JOBV .EQ. 'A', then LDV .GE. max(1,MV) .

WORK
  WORK is REAL array, dimension max(4,M+N).
  On entry,
  If JOBU .EQ. 'C' :
    WORK(1) = CTOL, where CTOL defines the threshold for convergence.
      The process stops if all columns of A are mutually
      orthogonal up to CTOL*EPS, EPS=SLAMCH('E').
      It is required that CTOL >= ONE, i.e. it is not
      allowed to force the routine to obtain orthogonality
      below EPSILON.
  On exit,
    WORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N)
      are the computed singular vcalues of A.
      (See description of SVA().)
    WORK(2) = NINT(WORK(2)) is the number of the computed nonzero
      singular values.
    WORK(3) = NINT(WORK(3)) is the number of the computed singular
      values that are larger than the underflow threshold.
    WORK(4) = NINT(WORK(4)) is the number of sweeps of Jacobi
      rotations needed for numerical convergence.
    WORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep.
      This is useful information in cases when SGESVJ did
      not converge, as it can be used to estimate whether
      the output is stil useful and for post festum analysis.
```

```
     WORK(6) = the largest absolute value over all sines of the
       Jacobi rotation angles in the last sweep. It can be
       useful for a post festum analysis.

 LWORK
   LWORK is INTEGER
   length of WORK, WORK >= MAX(6,M+N)

 INFO
   INFO is INTEGER
   = 0 : successful exit.
   < 0 : if INFO = -i, then the i-th argument had an illegal value
   > 0 : SGESVJ did not converge in the maximal allowed number (30)
         of sweeps. The output may still be useful. See the
         description of WORK.

 Further Details:

   The orthogonal N-by-N matrix V is obtained as a product of Jacobi
   plane rotations. The rotations are implemented as fast scaled
   rotations of Anda and Park [1]. In the case of underflow of the
   Jacobi angle, a modified Jacobi transformation of Drmac [4] is
   used. Pivot strategy uses column interchanges of de Rijk [2]. The
   relative accuracy of the computed singular values and the accuracy
   of the computed singular vectors (in angle metric) is as guaranteed
   by the theory of Demmel and Veselic [3]. The condition number that
   determines the accuracy in the full rank case is essentially
   min_{D=diag} kappa(A*D), where kappa(.) is the spectral condition
   number. The best performance of this Jacobi SVD procedure is
   achieved if used in an accelerated version of Drmac and Veselic
   [5,6], and it is the kernel routine in the SIGMA library [7]. Some
   tunning parameters (marked with [TP]) are available for the
   implementer.
   The computational range for the nonzero singular values is the
   machine number interval ( UNDERFLOW , OVERFLOW ). In extreme cases,
   even denormalized singular values can be computed with the
   corresponding gradual loss of accurate digits.

=====================================================================
Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgetf2 (M, N, A, LDA, IPIV, INFO)
           SGETF2 computes the LU factorization of a general m-by-n matrix
           using partial pivoting with row interchanges (unblocked algorithm).

Function/Subroutine Documentation
   subroutine sgetf2 (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       SGETF2 computes the LU factorization of a general m-by-n matrix using
       partial pivoting with row interchanges (unblocked algorithm).

Purpose:
   SGETF2 computes an LU factorization of a general m-by-n matrix A
   using partial pivoting with row interchanges.

   The factorization has the form  A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 2 BLAS version of the algorithm.

Parameters:

 M
```

```
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the m by n matrix to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U; the unit diagonal elements of L are not stored.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
  > 0: if INFO = k, U(k,k) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgetrf (M, N, A, LDA, IPIV, INFO)
           SGETRF

Function/Subroutine Documentation
   subroutine sgetrf (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       SGETRF

Purpose:
   SGETRF computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 3 BLAS version of the algorithm.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
```

```
  The number of columns of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the M-by-N matrix to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U; the unit diagonal elements of L are not stored.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       recursive subroutine sgetrf2 (M, N, A, LDA, IPIV, INFO)
           SGETRF2

Function/Subroutine Documentation
   recursive subroutine sgetrf2 (integer M, integer N, real, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       SGETRF2

Purpose:
   SGETRF2 computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
   A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

           [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
      A = [ --&mdash;|--&mdash; ]  with n1 = min(m,n)
```

```
                                        [ A11 ]
  The subroutine calls itself to factor [ --- ],
                                        [ A12 ]
                  [ A12 ]
  do the swaps on [ --- ], solve A12, update A22,
                  [ A22 ]

  then calls itself to factor A22 and do the swaps on A21.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M-by-N matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
      has been completed, but the factor U is exactly
      singular, and division by zero will occur if it is used
      to solve a system of equations.
```

           SGETRI

Function/Subroutine Documentation
   subroutine sgetri (integer N, real, dimension( lda, * ) A, integer LDA,
       integer, dimension( * ) IPIV, real, dimension( * ) WORK, integer LWORK,
       integer INFO)
       SGETRI

Purpose:
   SGETRI computes the inverse of a matrix using the LU factorization
   computed by SGETRF.

   This method inverts U and then computes inv(A) by solving the system
   inv(A)*L = inv(U) for inv(A).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the factors L and U from the factorization
   A = P*L*U as computed by SGETRF.
   On exit, if INFO = 0, the inverse of the original matrix A.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from SGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimal performance LWORK >= N*NB, where NB is
  the optimal blocksize returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero; the matrix is
        singular and its inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgetrs (TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           SGETRS

Function/Subroutine Documentation
   subroutine sgetrs (character TRANS, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       SGETRS

Purpose:
   SGETRS solves a system of linear equations
      A * X = B  or  A**T * X = B
   with a general N-by-N matrix A using the LU factorization computed
   by SGETRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B  (No transpose)
   = 'T':  A**T* X = B  (Transpose)
   = 'C':  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The factors L and U from the factorization A = P*L*U
   as computed by SGETRF.
```

```
LDA

  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from SGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine shgeqz (JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT,
           ALPHAR, ALPHAI, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, INFO)
           SHGEQZ

Function/Subroutine Documentation
   subroutine shgeqz (character JOB, character COMPQ, character COMPZ, integer
       N, integer ILO, integer IHI, real, dimension( ldh, * ) H, integer LDH,
       real, dimension( ldt, * ) T, integer LDT, real, dimension( * ) ALPHAR,
       real, dimension( * ) ALPHAI, real, dimension( * ) BETA, real,
       dimension( ldq, * ) Q, integer LDQ, real, dimension( ldz, * ) Z,
       integer LDZ, real, dimension( * ) WORK, integer LWORK, integer INFO)
       SHGEQZ

Purpose:
   SHGEQZ computes the eigenvalues of a real matrix pair (H,T),
   where H is an upper Hessenberg matrix and T is upper triangular,
   using the double-shift QZ method.
   Matrix pairs of this type are produced by the reduction to
   generalized upper Hessenberg form of a real matrix pair (A,B):

      A = Q1*H*Z1**T,  B = Q1*T*Z1**T,

   as computed by SGGHRD.

   If JOB='S', then the Hessenberg-triangular pair (H,T) is
   also reduced to generalized Schur form,

      H = Q*S*Z**T,  T = Q*P*Z**T,
```

```
   where Q and Z are orthogonal matrices, P is an upper triangular
   matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2
   diagonal blocks.

   The 1-by-1 blocks correspond to real eigenvalues of the matrix pair
   (H,T) and the 2-by-2 blocks correspond to complex conjugate pairs of
   eigenvalues.

   Additionally, the 2-by-2 upper triangular diagonal blocks of P
   corresponding to 2-by-2 blocks of S are reduced to positive diagonal
   form, i.e., if S(j+1,j) is non-zero, then P(j+1,j) = P(j,j+1) = 0,
   P(j,j) > 0, and P(j+1,j+1) > 0.

   Optionally, the orthogonal matrix Q from the generalized Schur
   factorization may be postmultiplied into an input matrix Q1, and the
   orthogonal matrix Z may be postmultiplied into an input matrix Z1.
   If Q1 and Z1 are the orthogonal matrices from SGGHRD that reduced
   the matrix pair (A,B) to generalized upper Hessenberg form, then the
   output matrices Q1*Q and Z1*Z are the orthogonal factors from the
   generalized Schur factorization of (A,B):

      A = (Q1*Q)*S*(Z1*Z)**T,  B = (Q1*Q)*P*(Z1*Z)**T.

   To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently,
   of (A,B)) are computed as a pair of values (alpha,beta), where alpha is
   complex and beta real.
   If beta is nonzero, lambda = alpha / beta is an eigenvalue of the
   generalized nonsymmetric eigenvalue problem (GNEP)
      A*x = lambda*B*x
   and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the
   alternate form of the GNEP
      mu*A*y = B*y.
   Real eigenvalues can be read directly from the generalized Schur
   form:
      alpha = S(i,i), beta = P(i,i).

Parameters:

 JOB
   JOB is CHARACTER*1
   = 'E': Compute eigenvalues only;
   = 'S': Compute eigenvalues and the Schur form.

 COMPQ
   COMPQ is CHARACTER*1
   = 'N': Left Schur vectors (Q) are not computed;
   = 'I': Q is initialized to the unit matrix and the matrix Q
      of left Schur vectors of (H,T) is returned;
   = 'V': Q must contain an orthogonal matrix Q1 on entry and
```

```
     the product Q1*Q is returned.

COMPZ
  COMPZ is CHARACTER*1
  = 'N': Right Schur vectors (Z) are not computed;
  = 'I': Z is initialized to the unit matrix and the matrix Z
     of right Schur vectors of (H,T) is returned;
  = 'V': Z must contain an orthogonal matrix Z1 on entry and
     the product Z1*Z is returned.

N
  N is INTEGER
  The order of the matrices H, T, Q, and Z.  N >= 0.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI mark the rows and columns of H which are in
  Hessenberg form.  It is assumed that A is already upper
  triangular in rows and columns 1:ILO-1 and IHI+1:N.
  If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H
  H is REAL array, dimension (LDH, N)
  On entry, the N-by-N upper Hessenberg matrix H.
  On exit, if JOB = 'S', H contains the upper quasi-triangular
  matrix S from the generalized Schur factorization.
  If JOB = 'E', the diagonal blocks of H match those of S, but
  the rest of H is unspecified.

LDH
  LDH is INTEGER
  The leading dimension of the array H.  LDH >= max( 1, N ).

T
  T is REAL array, dimension (LDT, N)
  On entry, the N-by-N upper triangular matrix T.
  On exit, if JOB = 'S', T contains the upper triangular
  matrix P from the generalized Schur factorization;
  2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S
  are reduced to positive diagonal form, i.e., if H(j+1,j) is
  non-zero, then T(j+1,j) = T(j,j+1) = 0, T(j,j) > 0, and
  T(j+1,j+1) > 0.
  If JOB = 'E', the diagonal blocks of T match those of P, but
  the rest of T is unspecified.

LDT
  LDT is INTEGER
```

```
  The leading dimension of the array T.  LDT >= max( 1, N ).

ALPHAR
  ALPHAR is REAL array, dimension (N)
  The real parts of each scalar alpha defining an eigenvalue of GNEP.

ALPHAI
  ALPHAI is REAL array, dimension (N)
  The imaginary parts of each scalar alpha defining an
  eigenvalue of GNEP.
  If ALPHAI(j) is zero, then the j-th eigenvalue is real; if
  positive, then the j-th and (j+1)-st eigenvalues are a
  complex conjugate pair, with ALPHAI(j+1) = -ALPHAI(j).

BETA
  BETA is REAL array, dimension (N)
  The scalars beta that define the eigenvalues of GNEP.
  Together, the quantities alpha = (ALPHAR(j),ALPHAI(j)) and
  beta = BETA(j) represent the j-th eigenvalue of the matrix
  pair (A,B), in one of the forms lambda = alpha/beta or
  mu = beta/alpha.  Since either lambda or mu may overflow,
  they should not, in general, be computed.

Q
  Q is REAL array, dimension (LDQ, N)
  On entry, if COMPZ = 'V', the orthogonal matrix Q1 used in
  the reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the orthogonal matrix of left Schur
  vectors of (H,T), and if COMPZ = 'V', the orthogonal matrix
  of left Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.  LDQ >= 1.
  If COMPQ='V' or 'I', then LDQ >= N.

Z
  Z is REAL array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the orthogonal matrix Z1 used in
  the reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the orthogonal matrix of
  right Schur vectors of (H,T), and if COMPZ = 'V', the
  orthogonal matrix of right Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1.
  If COMPZ='V' or 'I', then LDZ >= N.
```

```
 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   = 1,...,N: the QZ iteration did not converge.  (H,T) is not
      in Schur form, but ALPHAR(i), ALPHAI(i), and
      BETA(i), i=INFO+1,...,N should be correct.
   = N+1,...,2*N: the shift calculation failed.  (H,T) is not
      in Schur form, but ALPHAR(i), ALPHAI(i), and
      BETA(i), i=INFO-N+1,...,N should be correct.

Further Details:

 Iteration counters:

 JITER  -- counts iterations.
 IITER  -- counts iterations run since ILAST was last
           changed.  This is therefore reset only when a 1-by-1 or
           2-by-2 block deflates off the bottom.

==================================================================
Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sla_geamv (TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
           INCY)
           SLA_GEAMV computes a matrix-vector product using a general matrix
           to calculate error bounds.

Function/Subroutine Documentation
   subroutine sla_geamv (integer TRANS, integer M, integer N, real ALPHA,
       real, dimension( lda, * ) A, integer LDA, real, dimension( * ) X,
       integer INCX, real BETA, real, dimension( * ) Y, integer INCY)
       SLA_GEAMV computes a matrix-vector product using a general matrix to
       calculate error bounds.

Purpose:
   SLA_GEAMV  performs one of the matrix-vector operations

           y := alpha*abs(A)*abs(x) + beta*abs(y),
      or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
```

```
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
   Unchanged on exit.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.
   Unchanged on exit.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.
   Unchanged on exit.

 A
   A is REAL array of DIMENSION ( LDA, n )
   Before entry, the leading m by n part of the array A must
   contain the matrix of coefficients.
   Unchanged on exit.

 LDA
   LDA is INTEGER
   On entry, LDA specifies the first dimension of A as declared
   in the calling (sub) program. LDA must be at least
   max( 1, m ).
   Unchanged on exit.

 X
   X is REAL array, dimension
```

```
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n' and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is REAL
  Array of DIMENSION at least
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.

SYNOPSIS
   Functions/Subroutines
       real function sla_gercond (TRANS, N, A, LDA, AF, LDAF, IPIV, CMODE, C,
           INFO, WORK, IWORK)
           SLA_GERCOND estimates the Skeel condition number for a general
           matrix.

Function/Subroutine Documentation
   real function sla_gercond (character TRANS, integer N, real, dimension(
       lda, * ) A, integer LDA, real, dimension( ldaf, * ) AF, integer LDAF,
       integer, dimension( * ) IPIV, integer CMODE, real, dimension( * ) C,
       integer INFO, real, dimension( * ) WORK, integer, dimension( * ) IWORK)
       SLA_GERCOND estimates the Skeel condition number for a general matrix.

Purpose:
   SLA_GERCOND estimates the Skeel condition number of op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
```

```
  AF is REAL array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by SGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by SGETRF; row i of the matrix was interchanged
  with row IPIV(i).

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is REAL array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is REAL array, dimension (3*N).
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.2

SYNOPSIS
   Functions/Subroutines
       subroutine sla_gerfsx_extended (PREC_TYPE, TRANS_TYPE, N, NRHS, A, LDA,
           AF, LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS,
           ERRS_N, ERRS_C, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
           DZ_UB, IGNORE_CWISE, INFO)
           SLA_GERFSX_EXTENDED improves the computed solution to a system of
           linear equations for general matrices by performing extra-precise
           iterative refinement and provides error bounds and backward error
           estimates for the solution.

       IGNORE_CWISE, integer INFO)
       SLA_GERFSX_EXTENDED improves the computed solution to a system of
       linear equations for general matrices by performing extra-precise
       iterative refinement and provides error bounds and backward error
       estimates for the solution.

Purpose:
   SLA_GERFSX_EXTENDED improves the computed solution to a system of
```

```
  linear equations by performing extra-precise iterative refinement
  and provides error bounds and backward error estimates for the solution.
  This subroutine is called by SGERFSX to perform iterative refinement.
  In addition to normwise error bound, the code provides maximum
  componentwise error bound if possible. See comments for ERRS_N
  and ERRS_C for details of the error bounds. Note that this
  subroutine is only resonsible for setting the second fields of
  ERRS_N and ERRS_C.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 TRANS_TYPE
   TRANS_TYPE is INTEGER
   Specifies the transposition operation on A.
   The value is defined by ILATRANS(T) where T is a CHARACTER and
   T    = 'N':  No transpose
        = 'T':  Transpose
        = 'C':  Conjugate transpose

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by SGETRF.
```

```
LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by SGETRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is REAL array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
     max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by SLA_LIN_BERR.
```

```
N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERRS_N
  and ERRS_C).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERRS_N
  ERRS_N is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                     max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERRS_N(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_N(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERRS_C
```

```
  ERRS_C is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERRS_C is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERRS_C(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_C(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above.

RES
  RES is REAL array, dimension (N)
  Workspace to hold the intermediate residual.
```

```
AYB
  AYB is REAL array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.

DY
  DY is REAL array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is REAL array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
```

```
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to SGETRS had an illegal value

SYNOPSIS
   Functions/Subroutines
       real function sla_gerpvgrw (N, NCOLS, A, LDA, AF, LDAF)
           SLA_GERPVGRW

Function/Subroutine Documentation
   real function sla_gerpvgrw (integer N, integer NCOLS, real, dimension( lda,
       * ) A, integer LDA, real, dimension( ldaf, * ) AF, integer LDAF)
       SLA_GERPVGRW

Purpose:
   SLA_GERPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by SGETRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

SYNOPSIS
   Functions/Subroutines
       subroutine stgevc (SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL,
           VR, LDVR, MM, M, WORK, INFO)
           STGEVC

Function/Subroutine Documentation
   subroutine stgevc (character SIDE, character HOWMNY, logical, dimension( *
       ) SELECT, integer N, real, dimension( lds, * ) S, integer LDS, real,
       dimension( ldp, * ) P, integer LDP, real, dimension( ldvl, * ) VL,
       integer LDVL, real, dimension( ldvr, * ) VR, integer LDVR, integer MM,
       integer M, real, dimension( * ) WORK, integer INFO)
       STGEVC

Purpose:
   STGEVC computes some or all of the right and/or left eigenvectors of
   a pair of real matrices (S,P), where S is a quasi-triangular matrix
   and P is upper triangular.  Matrix pairs of this type are produced by
   the generalized Schur factorization of a matrix pair (A,B):

      A = Q*S*Z**T,  B = Q*P*Z**T

   as computed by SGGHRD + SHGEQZ.

   The right eigenvector x and the left eigenvector y of (S,P)
   corresponding to an eigenvalue w are defined by:

      S*x = w*P*x,  (y**H)*S = w*(y**H)*P,

   where y**H denotes the conjugate tranpose of y.
   The eigenvalues are not input to this routine, but are computed
   directly from the diagonal blocks of S and P.

   This routine returns the matrices X and/or Y of right and left
   eigenvectors of (S,P), or the products Z*X and/or Q*Y,
   where Z and Q are input matrices.
   If Q and Z are the orthogonal factors from the generalized Schur
   factorization of a matrix pair (A,B), then Z*X and Q*Y
   are the matrices of right and left eigenvectors of (A,B).

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'R': compute right eigenvectors only;
   = 'L': compute left eigenvectors only;
```

```
  = 'B': compute both right and left eigenvectors.

HOWMNY
  HOWMNY is CHARACTER*1
  = 'A': compute all right and/or left eigenvectors;
  = 'B': compute all right and/or left eigenvectors,
         backtransformed by the matrices in VR and/or VL;
  = 'S': compute selected right and/or left eigenvectors,
         specified by the logical array SELECT.

SELECT
  SELECT is LOGICAL array, dimension (N)
  If HOWMNY='S', SELECT specifies the eigenvectors to be
  computed.  If w(j) is a real eigenvalue, the corresponding
  real eigenvector is computed if SELECT(j) is .TRUE..
  If w(j) and w(j+1) are the real and imaginary parts of a
  complex eigenvalue, the corresponding complex eigenvector
  is computed if either SELECT(j) or SELECT(j+1) is .TRUE.,
  and on exit SELECT(j) is set to .TRUE. and SELECT(j+1) is
  set to .FALSE..
  Not referenced if HOWMNY = 'A' or 'B'.

N
  N is INTEGER
  The order of the matrices S and P.  N >= 0.

S
  S is REAL array, dimension (LDS,N)
  The upper quasi-triangular matrix S from a generalized Schur
  factorization, as computed by SHGEQZ.

LDS
  LDS is INTEGER
  The leading dimension of array S.  LDS >= max(1,N).

P
  P is REAL array, dimension (LDP,N)
  The upper triangular matrix P from a generalized Schur
  factorization, as computed by SHGEQZ.
  2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks
  of S must be in positive diagonal form.

LDP
  LDP is INTEGER
  The leading dimension of array P.  LDP >= max(1,N).

VL
  VL is REAL array, dimension (LDVL,MM)
  On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must
  contain an N-by-N matrix Q (usually the orthogonal matrix Q
```

```
  of left Schur vectors returned by SHGEQZ).
  On exit, if SIDE = 'L' or 'B', VL contains:
  if HOWMNY = 'A', the matrix Y of left eigenvectors of (S,P);
  if HOWMNY = 'B', the matrix Q*Y;
  if HOWMNY = 'S', the left eigenvectors of (S,P) specified by
       SELECT, stored consecutively in the columns of
       VL, in the same order as their eigenvalues.

  A complex eigenvector corresponding to a complex eigenvalue
  is stored in two consecutive columns, the first holding the
  real part, and the second the imaginary part.

  Not referenced if SIDE = 'R'.

LDVL
  LDVL is INTEGER
  The leading dimension of array VL.  LDVL >= 1, and if
  SIDE = 'L' or 'B', LDVL >= N.

VR
  VR is REAL array, dimension (LDVR,MM)
  On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must
  contain an N-by-N matrix Z (usually the orthogonal matrix Z
  of right Schur vectors returned by SHGEQZ).

  On exit, if SIDE = 'R' or 'B', VR contains:
  if HOWMNY = 'A', the matrix X of right eigenvectors of (S,P);
  if HOWMNY = 'B' or 'b', the matrix Z*X;
  if HOWMNY = 'S' or 's', the right eigenvectors of (S,P)
              specified by SELECT, stored consecutively in the
              columns of VR, in the same order as their eigenvalues.

  A complex eigenvector corresponding to a complex eigenvalue
  is stored in two consecutive columns, the first holding the
  real part and the second the imaginary part.

  Not referenced if SIDE = 'L'.

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1, and if
  SIDE = 'R' or 'B', LDVR >= N.

MM
  MM is INTEGER
  The number of columns in the arrays VL and/or VR. MM >= M.

M
  M is INTEGER
  The number of columns in the arrays VL and/or VR actually
```

```
   used to store the eigenvectors.  If HOWMNY = 'A' or 'B', M
   is set to N.  Each selected real eigenvector occupies one
   column and each selected complex eigenvector occupies two columns.

 WORK
   WORK is REAL array, dimension (6*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

Further Details:

   Allocation of workspace:
   ---------- -- ---------

   WORK( j ) = 1-norm of j-th column of A, above the diagonal
   WORK( N+j ) = 1-norm of j-th column of B, above the diagonal
   WORK( 2*N+1:3*N ) = real part of eigenvector
   WORK( 3*N+1:4*N ) = imaginary part of eigenvector
   WORK( 4*N+1:5*N ) = real part of back-transformed eigenvector
   WORK( 5*N+1:6*N ) = imaginary part of back-transformed eigenvector

   Rowwise vs. columnwise solution methods:
   ------- --  ---------- -------- -------

   Finding a generalized eigenvector consists basically of solving the
   singular triangular system

      (A - w B) x = 0     (for right) or:   (A - w B)**H y = 0  (for left)

   Consider finding the i-th right eigenvector (assume all eigenvalues
   are real). The equation to be solved is:

                n                   i
        0 = sum  C(j,k) v(k)  = sum  C(j,k) v(k)     for j = i,. . .,1
               k=j                 k=j

   where  C = (A - w B)  (The components v(i+1:n) are 0.)

   The "rowwise" method is:

   (1)  v(i) := 1
   for j = i-1,. . .,1:
                              i
        (2) compute  s = - sum C(j,k) v(k)   and
                            k=j+1
```

```
      (3) v(j) := s / C(j,j)

   Step 2 is sometimes called the "dot product" step, since it is an
   inner product between the j-th row and the portion of the eigenvector
   that has been computed so far.

   The "columnwise" method consists basically in doing the sums
   for all the rows in parallel.  As each v(j) is computed, the
   contribution of v(j) times the j-th column of C is added to the
   partial sums.  Since FORTRAN arrays are stored columnwise, this has
   the advantage that at each step, the elements of C that are accessed
   are adjacent to one another, whereas with the rowwise method, the
   elements accessed at a step are spaced LDS (and LDP) words apart.

   When finding left eigenvectors, the matrix in question is the
   transpose of the one in storage, so the rowwise method then
   actually accesses columns of A and B at each step, and so is the
   preferred method.
```

SYNOPSIS
   Functions/Subroutines
       subroutine stgexc (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
           IFST, ILST, WORK, LWORK, INFO)
           STGEXC

Function/Subroutine Documentation
   subroutine stgexc (logical WANTQ, logical WANTZ, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( ldq, * ) Q, integer LDQ, real, dimension(
       ldz, * ) Z, integer LDZ, integer IFST, integer ILST, real, dimension( *
       ) WORK, integer LWORK, integer INFO)
       STGEXC

Purpose:
   STGEXC reorders the generalized real Schur decomposition of a real
   matrix pair (A,B) using an orthogonal equivalence transformation

                   (A, B) = Q * (A, B) * Z**T,

   so that the diagonal block of (A, B) with row index IFST is moved
   to row ILST.

   (A, B) must be in generalized real Schur canonical form (as returned
   by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2
   diagonal blocks. B is upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.

            Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
            Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T

Parameters:

 WANTQ
   WANTQ is LOGICAL
```

```
  .TRUE. : update the left transformation matrix Q;
  .FALSE.: do not update Q.

WANTZ
  WANTZ is LOGICAL
  .TRUE. : update the right transformation matrix Z;
  .FALSE.: do not update Z.

N
  N is INTEGER
  The order of the matrices A and B. N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the matrix A in generalized real Schur canonical form.
  On exit, the updated matrix A, again in generalized
  real Schur canonical form.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,N).

B
  B is REAL array, dimension (LDB,N)
  On entry, the matrix B in generalized real Schur canonical form (A,B).
  On exit, the updated matrix B, again in generalized
  real Schur canonical form (A,B).

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

Q
  Q is REAL array, dimension (LDZ,N)
  On entry, if WANTQ = .TRUE., the orthogonal matrix Q.
  On exit, the updated matrix Q.
  If WANTQ = .FALSE., Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q. LDQ >= 1.
  If WANTQ = .TRUE., LDQ >= N.

Z
  Z is REAL array, dimension (LDZ,N)
  On entry, if WANTZ = .TRUE., the orthogonal matrix Z.
  On exit, the updated matrix Z.
  If WANTZ = .FALSE., Z is not referenced.

LDZ
```

```
  LDZ is INTEGER
  The leading dimension of the array Z. LDZ >= 1.
  If WANTZ = .TRUE., LDZ >= N.

IFST
  IFST is INTEGER

ILST
  ILST is INTEGER
  Specify the reordering of the diagonal blocks of (A, B).
  The block with row index IFST is moved to row ILST, by a
  sequence of swapping between adjacent blocks.
  On exit, if IFST pointed on entry to the second row of
  a 2-by-2 block, it is changed to point to the first row;
  ILST always points to the first row of the block in its
  final position (which may differ from its input value by
  +1 or -1). 1 <= IFST, ILST <= N.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >= 1 when N <= 1, otherwise LWORK >= 4*N + 16.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  =0:  successful exit.
  <0:  if INFO = -i, the i-th argument had an illegal value.
  =1:  The transformed matrix pair (A, B) would be too far
       from generalized Schur form; the problem is ill-
       conditioned. (A, B) may have been partially reordered,
       and ILST points to the first row of the current
       position of the block being moved.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgebak (JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
           CGEBAK

Function/Subroutine Documentation
   subroutine cgebak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, real, dimension( * ) SCALE, integer M, complex, dimension(
       ldv, * ) V, integer LDV, integer INFO)
       CGEBAK

Purpose:
   CGEBAK forms the right or left eigenvectors of a complex general
   matrix by backward transformation on the computed eigenvectors of the
   balanced matrix output by CGEBAL.

Parameters:

   JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N', do nothing, return immediately;
   = 'P', do backward transformation for permutation only;
   = 'S', do backward transformation for scaling only;
   = 'B', do backward transformations for both permutation and scaling.
   JOB must be the same as the argument JOB supplied to CGEBAL.

 SIDE
   SIDE is CHARACTER*1
   = 'R':  V contains right eigenvectors;
   = 'L':  V contains left eigenvectors.

 N
   N is INTEGER
   The number of rows of the matrix V.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   The integers ILO and IHI determined by CGEBAL.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 SCALE
```

```
  SCALE is REAL array, dimension (N)
  Details of the permutation and scaling factors, as returned by CGEBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is COMPLEX array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by CHSEIN or CTREVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the array V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgebal (JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
           CGEBAL

Function/Subroutine Documentation
   subroutine cgebal (character JOB, integer N, complex, dimension( lda, * )
       A, integer LDA, integer ILO, integer IHI, real, dimension( * ) SCALE,
       integer INFO)
       CGEBAL

Purpose:
   CGEBAL balances a general complex matrix A.  This involves, first,
   permuting A by a similarity transformation to isolate eigenvalues
   in the first 1 to ILO-1 and last IHI+1 to N elements on the
   diagonal; and second, applying a diagonal similarity transformation
   to rows and columns ILO to IHI to make the rows and columns as
   close in norm as possible.  Both steps are optional.

   Balancing may reduce the 1-norm of the matrix, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A:
   = 'N':  none:  simply set ILO = 1, IHI = N, SCALE(I) = 1.0
     for i = 1,...,N;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the input matrix A.
   On exit,  A is overwritten by the balanced matrix.
   If JOB = 'N', A is not referenced.
   See Further Details.

 LDA
   LDA is INTEGER
```

```
  The leading dimension of the array A.  LDA >= max(1,N).

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE
  SCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied to
  A.  If P(j) is the index of the row and column interchanged
  with row and column j and D(j) is the scaling factor
  applied to row and column j, then
  SCALE(j) = P(j)    for j = 1,...,ILO-1
           = D(j)    for j = ILO,...,IHI
           = P(j)    for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

  The permutations consist of row and column interchanges which put
  the matrix in the form

                         ( T1   X   Y  )
                P A P = (  0   B   Z  )
                         (  0   0   T2 )

  where T1 and T2 are upper triangular matrices whose eigenvalues lie
  along the diagonal.  The column indices ILO and IHI mark the starting
  and ending columns of the submatrix B. Balancing consists of applying
  a diagonal similarity transformation inv(D) * B * D to make the
  1-norms of each row of B and its corresponding column nearly equal.

  The output matrix is

                ( T1     X*D          Y    )
                (  0  inv(D)*B*D  inv(D)*Z ).
                (  0      0           T2   )

  Information about the permutations P and the diagonal matrix D is
  returned in the vector SCALE.
```

```
This subroutine is based on the EISPACK routine CBAL.

SYNOPSIS
   Functions/Subroutines
       subroutine cgebd2 (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
           CGEBD2 reduces a general matrix to bidiagonal form using an
           unblocked algorithm.

Function/Subroutine Documentation
   subroutine cgebd2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) D, real, dimension( * ) E, complex,
       dimension( * ) TAUQ, complex, dimension( * ) TAUP, complex, dimension(
       * ) WORK, integer INFO)
       CGEBD2 reduces a general matrix to bidiagonal form using an unblocked
       algorithm.

Purpose:
   CGEBD2 reduces a complex general m by n matrix A to upper or lower
```

```
  real bidiagonal form B by a unitary transformation: Q**H * A * P = B.

  If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the m by n general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
     overwritten with the upper bidiagonal matrix B; the
     elements below the diagonal, with the array TAUQ, represent
     the unitary matrix Q as a product of elementary
     reflectors, and the elements above the first superdiagonal,
     with the array TAUP, represent the unitary matrix P as
     a product of elementary reflectors;
   if m < n, the diagonal and the first subdiagonal are
     overwritten with the lower bidiagonal matrix B; the
     elements below the first subdiagonal, with the array TAUQ,
     represent the unitary matrix Q as a product of
     elementary reflectors, and the elements above the diagonal,
     with the array TAUP, represent the unitary matrix P as
     a product of elementary reflectors.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 D
   D is REAL array, dimension (min(M,N))
   The diagonal elements of the bidiagonal matrix B:
   D(i) = A(i,i).

 E
   E is REAL array, dimension (min(M,N)-1)
   The off-diagonal elements of the bidiagonal matrix B:
   if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
   if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

 TAUQ
   TAUQ is COMPLEX array dimension (min(M,N))
```

```
  The scalar factors of the elementary reflectors which
  represent the unitary matrix Q. See Further Details.

TAUP
  TAUP is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the unitary matrix P. See Further Details.

WORK
  WORK is COMPLEX array, dimension (max(M,N))

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value.

  The matrices Q and P are represented as products of elementary
  reflectors:

  If m >= n,

     Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

  Each H(i) and G(i) has the form:

     H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

  where tauq and taup are complex scalars, and v and u are complex
  vectors; v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in
  A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in
  A(i,i+2:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

  If m < n,

     Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

  Each H(i) and G(i) has the form:

     H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

  where tauq and taup are complex scalars, v and u are complex vectors;
  v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
  u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);
  tauq is stored in TAUQ(i) and taup in TAUP(i).

  The contents of A on exit are illustrated by the following examples:

    m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

    (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
```

```
  (  v1  d   e   u2  u2 )          (  e   d   u2  u2  u2  u2 )
  (  v1  v2  d   e   u3 )          (  v1  e   d   u3  u3  u3 )
  (  v1  v2  v3  d   e  )          (  v1  v2  e   d   u4  u4 )
  (  v1  v2  v3  v4  d  )          (  v1  v2  v3  e   d   u5 )
  (  v1  v2  v3  v4  v5 )
```

where d and e denote diagonal and off-diagonal elements of B, vi denotes an element of the vector defining H(i), and ui an element of the vector defining G(i).

SYNOPSIS
   Functions/Subroutines
       subroutine cgebrd (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
           CGEBRD

Function/Subroutine Documentation
   subroutine cgebrd (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) D, real, dimension( * ) E, complex,
       dimension( * ) TAUQ, complex, dimension( * ) TAUP, complex, dimension(
       * ) WORK, integer LWORK, integer INFO)
       CGEBRD

Purpose:
   CGEBRD reduces a general complex M-by-N matrix A to upper or lower
   bidiagonal form B by a unitary transformation: Q**H * A * P = B.

   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
```

```
  The number of rows in the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns in the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N general matrix to be reduced.
  On exit,
  if m >= n, the diagonal and the first superdiagonal are
    overwritten with the upper bidiagonal matrix B; the
    elements below the diagonal, with the array TAUQ, represent
    the unitary matrix Q as a product of elementary
    reflectors, and the elements above the first superdiagonal,
    with the array TAUP, represent the unitary matrix P as
    a product of elementary reflectors;
  if m < n, the diagonal and the first subdiagonal are
    overwritten with the lower bidiagonal matrix B; the
    elements below the first subdiagonal, with the array TAUQ,
    represent the unitary matrix Q as a product of
    elementary reflectors, and the elements above the diagonal,
    with the array TAUP, represent the unitary matrix P as
    a product of elementary reflectors.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

D
  D is REAL array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B:
  D(i) = A(i,i).

E
  E is REAL array, dimension (min(M,N)-1)
  The off-diagonal elements of the bidiagonal matrix B:
  if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
  if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ
  TAUQ is COMPLEX array dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the unitary matrix Q. See Further Details.

TAUP
  TAUP is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the unitary matrix P. See Further Details.
```

```
WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,M,N).
  For optimum performance LWORK >= (M+N)*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

  The matrices Q and P are represented as products of elementary
  reflectors:

  If m >= n,

     Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

  Each H(i) and G(i) has the form:

     H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

  where tauq and taup are complex scalars, and v and u are complex
  vectors; v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in
  A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in
  A(i,i+2:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

  If m < n,

     Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

  Each H(i) and G(i) has the form:

     H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

  where tauq and taup are complex scalars, and v and u are complex
  vectors; v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in
  A(i+2:m,i); u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in
  A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).
```

```
The contents of A on exit are illustrated by the following examples:

     m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

       (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
       (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
       (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
       (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
       (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
       (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal elements of B, vi
denotes an element of the vector defining H(i), and ui an element of
the vector defining G(i).

SYNOPSIS
   Functions/Subroutines
       subroutine cgecon (NORM, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
           CGECON

Function/Subroutine Documentation
   subroutine cgecon (character NORM, integer N, complex, dimension( lda, * )
       A, integer LDA, real ANORM, real RCOND, complex, dimension( * ) WORK,
       real, dimension( * ) RWORK, integer INFO)
       CGECON

Purpose:
```

```
   CGECON estimates the reciprocal of the condition number of a general
   complex matrix A, in either the 1-norm or the infinity-norm, using
   the LU factorization computed by CGETRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
       RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The factors L and U from the factorization A = P*L*U
   as computed by CGETRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 ANORM
   ANORM is REAL
   If NORM = '1' or 'O', the 1-norm of the original matrix A.
   If NORM = 'I', the infinity-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(norm(A) * norm(inv(A))).

 WORK
   WORK is COMPLEX array, dimension (2*N)

 RWORK
   RWORK is REAL array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgeequ (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           CGEEQU

Function/Subroutine Documentation
   subroutine cgeequ (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) R, real, dimension( * ) C, real
       ROWCND, real COLCND, real AMAX, integer INFO)
```

```
       CGEEQU

Purpose:
   CGEEQU computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

   R(i) and C(j) are restricted to be between SMLNUM = smallest safe
   number and BIGNUM = largest safe number.  Use of these scaling
   factors is not guaranteed to reduce the condition number of A but
   works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The M-by-N matrix whose equilibration factors are to be computed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 R
   R is REAL array, dimension (M)
   If INFO = 0 or INFO > M, R contains the row scale factors for A.

 C
   C is REAL array, dimension (N)
   If INFO = 0,  C contains the column scale factors for A.

 ROWCND
   ROWCND is REAL
   If INFO = 0 or INFO > M, ROWCND contains the ratio of the
   smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
   AMAX is neither too large nor too small, it is not worth
   scaling by R.

 COLCND
   COLCND is REAL
   If INFO = 0, COLCND contains the ratio of the smallest
```

```
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not
  worth scaling by C.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i,  and i is
        <= M:  the i-th row of A is exactly zero
        >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgeequb (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           CGEEQUB

Function/Subroutine Documentation
   subroutine cgeequb (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) R, real, dimension( * ) C, real
       ROWCND, real COLCND, real AMAX, integer INFO)
       CGEEQUB

Purpose:
   CGEEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from CGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).
```

```
Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The M-by-N matrix whose equilibration factors are to be computed.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 R
   R is REAL array, dimension (M)
   If INFO = 0 or INFO > M, R contains the row scale factors for A.

 C
   C is REAL array, dimension (N)
   If INFO = 0,  C contains the column scale factors for A.

 ROWCND
   ROWCND is REAL
   If INFO = 0 or INFO > M, ROWCND contains the ratio of the
   smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
   AMAX is neither too large nor too small, it is not worth
   scaling by R.

 COLCND
   COLCND is REAL
   If INFO = 0, COLCND contains the ratio of the smallest
   C(i) to the largest C(i).  If COLCND >= 0.1, it is not
   worth scaling by C.

 AMAX
   AMAX is REAL
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix
   should be scaled.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

```
> 0:  if INFO = i,  and i is
      <= M:  the i-th row of A is exactly zero
      >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgehd2 (N, ILO, IHI, A, LDA, TAU, WORK, INFO)
           CGEHD2 reduces a general square matrix to upper Hessenberg form
           using an unblocked algorithm.

Function/Subroutine Documentation
```

```
   subroutine cgehd2 (integer N, integer ILO, integer IHI, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( * ) TAU, complex,
       dimension( * ) WORK, integer INFO)
       CGEHD2 reduces a general square matrix to upper Hessenberg form using
       an unblocked algorithm.

Purpose:
   CGEHD2 reduces a complex general matrix A to upper Hessenberg form H
   by a unitary similarity transformation:  Q**H * A * Q = H .

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to CGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= max(1,N).

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the n by n general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the unitary matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is COMPLEX array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX array, dimension (N)

 INFO
   INFO is INTEGER
```

```
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value.

The matrix Q is represented as a product of (ihi-ilo) elementary
reflectors

      Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Each H(i) has the form

      H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with
n = 7, ilo = 2 and ihi = 6:

on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
(     a   a   a   a   a   a )    (      a   h   h   h   h   a )
(     a   a   a   a   a   a )    (      h   h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
(                         a )    (                          a )

where a denotes an element of the original matrix A, h denotes a
modified element of the upper Hessenberg matrix H, and vi denotes an
element of the vector defining H(i).

   This file is a slight modification of LAPACK-3.0's DGEHRD
   subroutine incorporating improvements proposed by Quintana-Orti and
   Van de Geijn (2006). (See DLAHR2.)

SYNOPSIS
   Functions/Subroutines
       subroutine cgehrd (N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
           CGEHRD

Function/Subroutine Documentation
   subroutine cgehrd (integer N, integer ILO, integer IHI, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( * ) TAU, complex,
       dimension( * ) WORK, integer LWORK, integer INFO)
       CGEHRD

Purpose:
   CGEHRD reduces a complex general matrix A to upper Hessenberg form H by
   an unitary similarity transformation:  Q**H * A * Q = H .

Parameters:

 N
   N is INTEGER
```

```
  The order of the matrix A.  N >= 0.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER

  It is assumed that A is already upper triangular in rows
  and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
  set by a previous call to CGEBAL; otherwise they should be
  set to 1 and N respectively. See Further Details.
  1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N general matrix to be reduced.
  On exit, the upper triangle and the first subdiagonal of A
  are overwritten with the upper Hessenberg matrix H, and the
  elements below the first subdiagonal, with the array TAU,
  represent the unitary matrix Q as a product of elementary
  reflectors. See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

TAU
  TAU is COMPLEX array, dimension (N-1)
  The scalar factors of the elementary reflectors (see Further
  Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORK
  WORK is COMPLEX array, dimension (LWORK)
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,N).
  For good performance, LWORK should generally be larger.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

```
The matrix Q is represented as a product of (ihi-ilo) elementary
reflectors

   Q = H(ilo) H(ilo+1) . . . H(ihi-1).

Each H(i) has the form

   H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with
n = 7, ilo = 2 and ihi = 6:

on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
(     a   a   a   a   a   a )    (      a   h   h   h   h   a )
(     a   a   a   a   a   a )    (      h   h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
(                         a )    (                          a )

where a denotes an element of the original matrix A, h denotes a
modified element of the upper Hessenberg matrix H, and vi denotes an
element of the vector defining H(i).

This file is a slight modification of LAPACK-3.0's DGEHRD
subroutine incorporating improvements proposed by Quintana-Orti and
Van de Geijn (2006). (See DLAHR2.)

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgelq2 (M, N, A, LDA, TAU, WORK, INFO)
           CGELQ2 computes the LQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine cgelq2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer INFO)
       CGELQ2 computes the LQ factorization of a general rectangular matrix
       using an unblocked algorithm.
```

```
Purpose:
   CGELQ2 computes an LQ factorization of a complex m by n matrix A:
   A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and below the diagonal of the array
   contain the m by min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the unitary matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

   The matrix Q is represented as a product of elementary reflectors

      Q = H(k)**H . . . H(2)**H H(1)**H, where k = min(m,n).

   Each H(i) has the form

      H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(1:i-1) = 0 and v(i) = 1; conjg(v(i+1:n)) is stored on exit in
```

A(i,i+1:n), and tau in TAU(i).

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgelqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           CGELQF

Function/Subroutine Documentation
   subroutine cgelqf (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer LWORK, integer INFO)
       CGELQF

Purpose:
   CGELQF computes an LQ factorization of a complex M-by-N matrix A:
   A = L * Q.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the elements on and below the diagonal of the array
  contain the m-by-min(m,n) lower trapezoidal matrix L (L is
  lower triangular if m <= n); the elements above the diagonal,
  with the array TAU, represent the unitary matrix Q as a
  product of elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,M).
  For optimum performance LWORK >= M*NB, where NB is the
  optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

  The matrix Q is represented as a product of elementary reflectors

     Q = H(k)**H . . . H(2)**H H(1)**H, where k = min(m,n).
```

```
Each H(i) has the form

   H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i-1) = 0 and v(i) = 1; conjg(v(i+1:n)) is stored on exit in
A(i,i+1:n), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgemqrt (SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC,
           WORK, INFO)
           CGEMQRT

Function/Subroutine Documentation
   subroutine cgemqrt (character SIDE, character TRANS, integer M, integer N,
       integer K, integer NB, complex, dimension( ldv, * ) V, integer LDV,
       complex, dimension( ldt, * ) T, integer LDT, complex, dimension( ldc, *
       ) C, integer LDC, complex, dimension( * ) WORK, integer INFO)
       CGEMQRT

Purpose:
   CGEMQRT overwrites the general complex M-by-N matrix C with
```

```
                    SIDE = 'L'     SIDE = 'R'
    TRANS = 'N':      Q C            C Q
    TRANS = 'C':    Q**H C            C Q**H

  where Q is a complex orthogonal matrix defined as the product of K
  elementary reflectors:

     Q = H(1) H(2) . . . H(K) = I - V T V**H

  generated using the compact WY representation as returned by CGEQRT.

  Q is of order M if SIDE = 'L' and of order N  if SIDE = 'R'.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'L': apply Q or Q**H from the Left;
   = 'R': apply Q or Q**H from the Right.

 TRANS
   TRANS is CHARACTER*1
   = 'N':  No transpose, apply Q;
   = 'C':  Transpose, apply Q**H.

 M
   M is INTEGER
   The number of rows of the matrix C. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix C. N >= 0.

 K
   K is INTEGER
   The number of elementary reflectors whose product defines
   the matrix Q.
   If SIDE = 'L', M >= K >= 0;
   if SIDE = 'R', N >= K >= 0.

 NB
   NB is INTEGER
   The block size used for the storage of T.  K >= NB >= 1.
   This must be the same value of NB used to generate T in CGEQRT.

 V
   V is COMPLEX array, dimension (LDV,K)
   The i-th column must contain the vector which defines the
   elementary reflector H(i), for i = 1,2,...,k, as returned by
   CGEQRT in the first K columns of its array argument A.
```

```
LDV
  LDV is INTEGER
  The leading dimension of the array V.
  If SIDE = 'L', LDA >= max(1,M);
  if SIDE = 'R', LDA >= max(1,N).

T
  T is COMPLEX array, dimension (LDT,K)
  The upper triangular factors of the block reflectors
  as returned by CGEQRT, stored as a NB-by-N matrix.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= NB.

C
  C is COMPLEX array, dimension (LDC,N)
  On entry, the M-by-N matrix C.
  On exit, C is overwritten by Q C, Q**H C, C Q**H or C Q.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M).

WORK
  WORK is COMPLEX array. The dimension of WORK is
  N*NB if SIDE = 'L', or  M*NB if SIDE = 'R'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

Man Page Details
====================================================================

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine cgeql2 (M, N, A, LDA, TAU, WORK, INFO)
           CGEQL2 computes the QL factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine cgeql2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer INFO)
       CGEQL2 computes the QL factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   CGEQL2 computes a QL factorization of a complex m by n matrix A:
   A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the n by n lower triangular matrix L;
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the m by n lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   unitary matrix Q as a product of elementary reflectors
   (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX array, dimension (N)

 INFO
   INFO is INTEGER
```

```
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

 The matrix Q is represented as a product of elementary reflectors

    Q = H(k) . . . H(2) H(1), where k = min(m,n).

 Each H(i) has the form

    H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
   A(1:m-k+i-1,n-k+i), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqlf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           CGEQLF

Function/Subroutine Documentation
   subroutine cgeqlf (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer LWORK, integer INFO)
```

```
       CGEQLF

Purpose:
   CGEQLF computes a QL factorization of a complex M-by-N matrix A:
   A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L;
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the M-by-N lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   unitary matrix Q as a product of elementary reflectors
   (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.
```

```
INFO
INFO is INTEGER
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value

The matrix Q is represented as a product of elementary reflectors

    Q = H(k) . . . H(2) H(1), where k = min(m,n).

Each H(i) has the form

    H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
A(1:m-k+i-1,n-k+i), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqp3 (M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK, INFO)
           CGEQP3

Function/Subroutine Documentation
   subroutine cgeqp3 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) JPVT, complex, dimension( * ) TAU,
       complex, dimension( * ) WORK, integer LWORK, real, dimension( * )
       RWORK, integer INFO)
       CGEQP3

Purpose:
   CGEQP3 computes a QR factorization with column pivoting of a
   matrix A:  A*P = Q*R  using Level 3 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
```

```
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the upper triangle of the array contains the
  min(M,N)-by-N upper trapezoidal matrix R; the elements below
  the diagonal, together with the array TAU, represent the
  unitary matrix Q as a product of min(M,N) elementary reflectors.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

JPVT
  JPVT is INTEGER array, dimension (N)
  On entry, if JPVT(J).ne.0, the J-th column of A is permuted
  to the front of A*P (a leading column); if JPVT(J)=0,
  the J-th column of A is a free column.
  On exit, if JPVT(J)=K, then the J-th column of A*P was the
  the K-th column of A.

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= N+1.
  For optimal performance LWORK >= ( N+1 )*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0: successful exit.
  < 0: if INFO = -i, the i-th argument had an illegal value.

  The matrix Q is represented as a product of elementary reflectors

     Q = H(1) H(2) . . . H(k), where k = min(m,n).
```

```
Each H(i) has the form

   H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a real/complex vector
with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in
A(i+1:m,i), and tau in TAU(i).
```

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqr2 (M, N, A, LDA, TAU, WORK, INFO)
           CGEQR2 computes the QR factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine cgeqr2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer INFO)
       CGEQR2 computes the QR factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   CGEQR2 computes a QR factorization of a complex m by n matrix A:
   A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the m by n matrix A.
  On exit, the elements on and above the diagonal of the array
  contain the min(m,n) by n upper trapezoidal matrix R (R is
  upper triangular if m >= n); the elements below the diagonal,
  with the array TAU, represent the unitary matrix Q as a
  product of elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

The matrix Q is represented as a product of elementary reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - tau * v * v**H

  where tau is a complex scalar, and v is a complex vector with
  v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
  and tau in TAU(i).

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqr2p (M, N, A, LDA, TAU, WORK, INFO)
           CGEQR2P computes the QR factorization of a general rectangular
           matrix with non-negative diagonal elements using an unblocked
           algorithm.

Function/Subroutine Documentation
   subroutine cgeqr2p (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer INFO)
       CGEQR2P computes the QR factorization of a general rectangular matrix
       with non-negative diagonal elements using an unblocked algorithm.

Purpose:
   CGEQR2P computes a QR factorization of a complex m by n matrix A:
   A = Q * R. The diagonal entries of R are real and nonnegative.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n). The diagonal entries of R are
   real and nonnegative; the elements below the diagonal,
   with the array TAU, represent the unitary matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
```

```
  WORK is COMPLEX array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

  The matrix Q is represented as a product of elementary reflectors

      Q = H(1) H(2) . . . H(k), where k = min(m,n).

  Each H(i) has the form

     H(i) = I - tau * v * v**H

  where tau is a complex scalar, and v is a complex vector with
  v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
  and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqrf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           CGEQRF

Function/Subroutine Documentation
   subroutine cgeqrf (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer LWORK, integer INFO)
       CGEQRF

Purpose:
   CGEQRF computes a QR factorization of a complex M-by-N matrix A:
   A = Q * R.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the elements on and above the diagonal of the array
  contain the min(M,N)-by-N upper trapezoidal matrix R (R is
  upper triangular if m >= n); the elements below the diagonal,
  with the array TAU, represent the unitary matrix Q as a
  product of min(m,n) elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimum performance LWORK >= N*NB, where NB is
  the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

  The matrix Q is represented as a product of elementary reflectors

     Q = H(1) H(2) . . . H(k), where k = min(m,n).
```

```
Each H(i) has the form

   H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqrfp (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           CGEQRFP

Function/Subroutine Documentation
   subroutine cgeqrfp (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer LWORK, integer INFO)
       CGEQRFP

Purpose:
   CGEQRFP computes a QR factorization of a complex M-by-N matrix A:
   A = Q * R. The diagonal entries of R are real and nonnegative.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the elements on and above the diagonal of the array
  contain the min(M,N)-by-N upper trapezoidal matrix R (R is
  upper triangular if m >= n). The diagonal entries of R
  are real and nonnegative; the elements below the diagonal,
  with the array TAU, represent the unitary matrix Q as a
  product of min(m,n) elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimum performance LWORK >= N*NB, where NB is
  the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

  The matrix Q is represented as a product of elementary reflectors

     Q = H(1) H(2) . . . H(k), where k = min(m,n).
```

```
Each H(i) has the form

   H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
and tau in TAU(i).
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqrt (M, N, NB, A, LDA, T, LDT, WORK, INFO)
           CGEQRT

Function/Subroutine Documentation
   subroutine cgeqrt (integer M, integer N, integer NB, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldt, * ) T, integer LDT,
       complex, dimension( * ) WORK, integer INFO)
       CGEQRT

Purpose:
   CGEQRT computes a blocked QR factorization of a complex M-by-N matrix A
   using the compact WY representation of Q.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

NB
  NB is INTEGER
  The block size to be used in the blocked QR.  MIN(M,N) >= NB >= 1.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit, the elements on and above the diagonal of the array
  contain the min(M,N)-by-N upper trapezoidal matrix R (R is
  upper triangular if M >= N); the elements below the diagonal
  are the columns of V.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

T
  T is COMPLEX array, dimension (LDT,MIN(M,N))
  The upper triangular block reflectors stored in compact form
  as a sequence of upper triangular blocks.  See below
  for further details.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= NB.

WORK
  WORK is COMPLEX array, dimension (NB*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

  The matrix V stores the elementary reflectors H(i) in the i-th column
  below the diagonal. For example, if M=5 and N=3, the matrix V is

          V = (  1       )
              ( v1  1    )
              ( v1 v2  1 )
              ( v1 v2 v3 )
```

```
              ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.

   Let K=MIN(M,N).  The number of blocks is B = ceiling(K/NB), where each
   block is of order NB except for the last block, which is of order
   IB = K - (B-1)*NB.  For each of the B blocks, a upper triangular block
   reflector factor is computed: T1, T2, ..., TB.  The NB-by-NB (and IB-by-IB
   for the last block) T's are stored in the NB-by-N matrix T as

      T = (T1 T2 ... TB).

==========================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgeqrt2 (M, N, A, LDA, T, LDT, INFO)
           CGEQRT2 computes a QR factorization of a general real or complex
           matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   subroutine cgeqrt2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( ldt, * ) T, integer LDT, integer INFO)
       CGEQRT2 computes a QR factorization of a general real or complex matrix
       using the compact WY representation of Q.

Purpose:
   CGEQRT2 computes a QR factorization of a complex M-by-N matrix A,
   using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the complex M-by-N matrix A.  On exit, the elements on and
  above the diagonal contain the N-by-N upper triangular matrix R; the
  elements below the diagonal are the columns of V.  See below for
  further details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

T
  T is COMPLEX array, dimension (LDT,N)
  The N-by-N upper triangular factor of the block reflector.
  The elements on and above the diagonal contain the block
  reflector T; the elements below the diagonal are not used.
  See below for further details.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

  The matrix V stores the elementary reflectors H(i) in the i-th column
  below the diagonal. For example, if M=5 and N=3, the matrix V is

          V = (  1       )
              ( v1  1    )
              ( v1 v2  1 )
              ( v1 v2 v3 )
              ( v1 v2 v3 )

  where the vi's represent the vectors which define H(i), which are returned
  in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
  block reflector H is then given by

     H = I - V * T * V**H

  where V**H is the conjugate transpose of V.

==================================================================

SYNOPSIS
   Functions/Subroutines
       recursive subroutine cgeqrt3 (M, N, A, LDA, T, LDT, INFO)
           CGEQRT3 recursively computes a QR factorization of a general real
           or complex matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   recursive subroutine cgeqrt3 (integer M, integer N, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldt, * ) T, integer LDT,
       integer INFO)
       CGEQRT3 recursively computes a QR factorization of a general real or
       complex matrix using the compact WY representation of Q.

Purpose:
   CGEQRT3 recursively computes a QR factorization of a complex M-by-N
   matrix A, using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the complex M-by-N matrix A.  On exit, the elements on and
   above the diagonal contain the N-by-N upper triangular matrix R; the
   elements below the diagonal are the columns of V.  See below for
   further details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).
```

```
T
  T is COMPLEX array, dimension (LDT,N)
  The N-by-N upper triangular factor of the block reflector.
  The elements on and above the diagonal contain the block
  reflector T; the elements below the diagonal are not used.
  See below for further details.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

  The matrix V stores the elementary reflectors H(i) in the i-th column
  below the diagonal. For example, if M=5 and N=3, the matrix V is

          V = (  1       )
              ( v1  1    )
              ( v1 v2  1 )
              ( v1 v2 v3 )
              ( v1 v2 v3 )

  where the vi's represent the vectors which define H(i), which are returned
  in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
  block reflector H is then given by

     H = I - V * T * V**H

  where V**H is the conjugate transpose of V.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgerfs (TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, RWORK, INFO)
           CGERFS

Function/Subroutine Documentation
   subroutine cgerfs (character TRANS, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF,
       integer LDAF, integer, dimension( * ) IPIV, complex, dimension( ldb, *
       ) B, integer LDB, complex, dimension( ldx, * ) X, integer LDX, real,
       dimension( * ) FERR, real, dimension( * ) BERR, complex, dimension( * )
       WORK, real, dimension( * ) RWORK, integer INFO)
       CGERFS

Purpose:
   CGERFS improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates for
   the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  The original N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by CGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from CGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.
```

```
 BERR
   BERR is REAL array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX array, dimension (2*N)

 RWORK
   RWORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

   ITMAX is the maximum number of steps of iterative refinement.
```

      WORK, real, dimension( * ) RWORK, integer INFO)
      CGERFSX

Purpose:
   CGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
```

```
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The original N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by CGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from CGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.
  If R is accessed, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.
  If C is accessed, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
```

```
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
        max_j (abs(XTRUE(j,i) - X(j,i)))
       ------------------------------
             max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information returned.
```

```
  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
          reciprocal condition number.  Compared with the threshold
          sqrt(n) * slamch('Epsilon') to determine if the error
          estimate is "guaranteed". These reciprocal condition
          numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
          appropriately scaled matrix Z.
          Let Z = S*A, where S scales each row by a power of the
          radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
              abs(XTRUE(j,i) - X(j,i))
      max_j ----------------------
                   abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
```

```
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
          reciprocal condition number.  Compared with the threshold
          sqrt(n) * slamch('Epsilon') to determine if the error
          estimate is "guaranteed". These reciprocal condition
          numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
          appropriately scaled matrix Z.
          Let Z = S*(A*diag(x)), where x is the solution for the
          current right-hand side and S scales each row of
          A*diag(x) by a power of the radix so all absolute row
          sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.

  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.

  Default: 10
    Aggressive: Set to 100 to permit convergence using approximate
                factorizations or factorizations other than LU. If
```

```
                the factorization uses a technique other than
                Gaussian elimination, the guarantees in
                err_bnds_norm and err_bnds_comp may no longer be
                trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
    will attempt to find a solution with small componentwise
    relative error in the double-precision algorithm.  Positive
    is true, 0.0 is false.

  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
        guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or
      ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine cgerq2 (M, N, A, LDA, TAU, WORK, INFO)
           CGERQ2 computes the RQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine cgerq2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer INFO)
       CGERQ2 computes the RQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   CGERQ2 computes an RQ factorization of a complex m by n matrix A:
   A = R * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
```

```
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the m by n matrix A.
  On exit, if m <= n, the upper triangle of the subarray
  A(1:m,n-m+1:n) contains the m by m upper triangular matrix R;
  if m >= n, the elements on and above the (m-n)-th subdiagonal
  contain the m by n upper trapezoidal matrix R; the remaining
  elements, with the array TAU, represent the unitary matrix
  Q as a product of elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX array, dimension (M)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

  The matrix Q is represented as a product of elementary reflectors

     Q = H(1)**H H(2)**H . . . H(k)**H, where k = min(m,n).

  Each H(i) has the form

     H(i) = I - tau * v * v**H

  where tau is a complex scalar, and v is a complex vector with
  v(n-k+i+1:n) = 0 and v(n-k+i) = 1; conjg(v(1:n-k+i-1)) is stored on
  exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine cgerqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           CGERQF

Function/Subroutine Documentation
   subroutine cgerqf (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, complex, dimension( * ) TAU, complex, dimension( * ) WORK,
       integer LWORK, integer INFO)
       CGERQF

Purpose:
   CGERQF computes an RQ factorization of a complex M-by-N matrix A:
   A = R * Q.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  if m <= n, the upper triangle of the subarray
  A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R;
  if m >= n, the elements on and above the (m-n)-th subdiagonal
  contain the M-by-N upper trapezoidal matrix R;
  the remaining elements, with the array TAU, represent the
  unitary matrix Q as a product of min(m,n) elementary
  reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,M).
  For optimum performance LWORK >= M*NB, where NB is
  the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

  The matrix Q is represented as a product of elementary reflectors
```

```
   Q = H(1)**H H(2)**H . . . H(k)**H, where k = min(m,n).

Each H(i) has the form

   H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(n-k+i+1:n) = 0 and v(n-k+i) = 1; conjg(v(1:n-k+i-1)) is stored on
exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgesvj (JOBA, JOBU, JOBV, M, N, A, LDA, SVA, MV, V, LDV,
           CWORK, LWORK, RWORK, LRWORK, INFO)
           CGESVJ

Function/Subroutine Documentation
   subroutine cgesvj (character*1 JOBA, character*1 JOBU, character*1 JOBV,
       integer M, integer N, complex, dimension( lda, * ) A, integer LDA,
       real, dimension( n ) SVA, integer MV, complex, dimension( ldv, * ) V,
       integer LDV, complex, dimension( lwork ) CWORK, integer LWORK, real,
       dimension( lrwork ) RWORK, integer LRWORK, integer INFO)
       CGESVJ

Purpose:

Parameters:

   JOBA
   JOBA is CHARACTER* 1
   Specifies the structure of A.
   = 'L': The input matrix A is lower triangular;
   = 'U': The input matrix A is upper triangular;
   = 'G': The input matrix A is general M-by-N matrix, M >= N.

 JOBU
   JOBU is CHARACTER*1
   Specifies whether to compute the left singular vectors
   (columns of U):
   = 'U': The left singular vectors corresponding to the nonzero
      singular values are computed and returned in the leading
      columns of A. See more details in the description of A.
      The default numerical orthogonality threshold is set to
      approximately TOL=CTOL*EPS, CTOL=SQRT(M), EPS=SLAMCH('E').
   = 'C': Analogous to JOBU='U', except that user can control the
      level of numerical orthogonality of the computed left
      singular vectors. TOL can be set to TOL = CTOL*EPS, where
      CTOL is given on input in the array WORK.
      No CTOL smaller than ONE is allowed. CTOL greater
      than 1 / EPS is meaningless. The option 'C'
      can be used if M*EPS is satisfactory orthogonality
      of the computed left singular vectors, so CTOL=M could
```

```
     save few sweeps of Jacobi rotations.
     See the descriptions of A and WORK(1).
  = 'N': The matrix U is not computed. However, see the description of A.

JOBV
  JOBV is CHARACTER*1
  Specifies whether to compute the right singular vectors, that
  is, the matrix V:
  = 'V' : the matrix V is computed and returned in the array V
  = 'A' : the Jacobi rotations are applied to the MV-by-N
    array V. In other words, the right singular vector
    matrix V is not computed explicitly; instead it is
    applied to an MV-by-N matrix initially stored in the
    first MV rows of V.
  = 'N' : the matrix V is not computed and the array V is not referenced

M
  M is INTEGER
  The number of rows of the input matrix A. 1/SLAMCH('E') > M >= 0.

N
  N is INTEGER
  The number of columns of the input matrix A.
  M >= N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the M-by-N matrix A.
  On exit,
  If JOBU .EQ. 'U' .OR. JOBU .EQ. 'C':
    If INFO .EQ. 0 :
      RANKA orthonormal columns of U are returned in the
      leading RANKA columns of the array A. Here RANKA <= N
      is the number of computed singular values of A that are
      above the underflow threshold SLAMCH('S'). The singular
      vectors corresponding to underflowed or zero singular
      values are not computed. The value of RANKA is returned
      in the array RWORK as RANKA=NINT(RWORK(2)). Also see the
      descriptions of SVA and RWORK. The computed columns of U
      are mutually numerically orthogonal up to approximately
      TOL=SQRT(M)*EPS (default); or TOL=CTOL*EPS (JOBU.EQ.'C'),
      see the description of JOBU.
    If INFO .GT. 0,
     the procedure CGESVJ did not converge in the given number
     of iterations (sweeps). In that case, the computed
     columns of U may not be orthogonal up to TOL. The output
     U (stored in A), SIGMA (given by the computed singular
     values in SVA(1:N)) and V is still a decomposition of the
     input matrix A in the sense that the residual
        || A - SCALE * U * SIGMA * V^* ||_2 / ||A||_2 is small.
```

```
  If JOBU .EQ. 'N':
    If INFO .EQ. 0 :
      Note that the left singular vectors are 'for free' in the
      one-sided Jacobi SVD algorithm. However, if only the
      singular values are needed, the level of numerical
      orthogonality of U is not an issue and iterations are
      stopped when the columns of the iterated matrix are
      numerically orthogonal up to approximately M*EPS. Thus,
      on exit, A contains the columns of U scaled with the
      corresponding singular values.
    If INFO .GT. 0 :
      the procedure CGESVJ did not converge in the given number
      of iterations (sweeps).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

  SVA
  SVA is REAL array, dimension (N)
  On exit,
  If INFO .EQ. 0 :
     depending on the value SCALE = RWORK(1), we have:
     If SCALE .EQ. ONE:
       SVA(1:N) contains the computed singular values of A.
       During the computation SVA contains the Euclidean column
       norms of the iterated matrices in the array A.
     If SCALE .NE. ONE:
       The singular values of A are SCALE*SVA(1:N), and this
       factored representation is due to the fact that some of the
       singular values of A might underflow or overflow.
  If INFO .GT. 0 :
    the procedure CGESVJ did not converge in the given number of
    iterations (sweeps) and SCALE*SVA(1:N) may not be accurate.

MV
  MV is INTEGER
  If JOBV .EQ. 'A', then the product of Jacobi rotations in CGESVJ
  is applied to the first MV rows of V. See the description of JOBV.

V
  V is COMPLEX array, dimension (LDV,N)
  If JOBV = 'V', then V contains on exit the N-by-N matrix of
       the right singular vectors;
  If JOBV = 'A', then V contains the product of the computed right
       singular vector matrix and the initial matrix in the array V.
  If JOBV = 'N', then V is not referenced.

LDV
  LDV is INTEGER
```

```
  The leading dimension of the array V, LDV .GE. 1.
  If JOBV .EQ. 'V', then LDV .GE. max(1,N).
  If JOBV .EQ. 'A', then LDV .GE. max(1,MV) .

CWORK
  CWORK is COMPLEX array, dimension M+N. Used as work space. LWORK

LWORK is INTEGER
  Length of CWORK, LWORK >= M+N.

RWORK
  RWORK is REAL array, dimension max(6,M+N).
  On entry,
  If JOBU .EQ. 'C' :
  RWORK(1) = CTOL, where CTOL defines the threshold for convergence.
  The process stops if all columns of A are mutually
  orthogonal up to CTOL*EPS, EPS=SLAMCH('E').
  It is required that CTOL >= ONE, i.e. it is not
  allowed to force the routine to obtain orthogonality
  below EPSILON.
  On exit,
  RWORK(1) = SCALE is the scaling factor such that SCALE*SVA(1:N)
     are the computed singular values of A.
     (See description of SVA().)
  RWORK(2) = NINT(RWORK(2)) is the number of the computed nonzero
     singular values.
  RWORK(3) = NINT(RWORK(3)) is the number of the computed singular
     values that are larger than the underflow threshold.
  RWORK(4) = NINT(RWORK(4)) is the number of sweeps of Jacobi
     rotations needed for numerical convergence.
  RWORK(5) = max_{i.NE.j} |COS(A(:,i),A(:,j))| in the last sweep.
     This is useful information in cases when CGESVJ did
     not converge, as it can be used to estimate whether
     the output is stil useful and for post festum analysis.
  RWORK(6) = the largest absolute value over all sines of the
     Jacobi rotation angles in the last sweep. It can be
     useful for a post festum analysis.

LRWORK
  LRWORK is INTEGER Length of RWORK, LRWORK >= MAX(6,N).

INFO
  INFO is INTEGER
  = 0 : successful exit.
  < 0 : if INFO = -i, then the i-th argument had an illegal value
  > 0 : CGESVJ did not converge in the maximal allowed number
        (NSWEEP=30) of sweeps. The output may still be useful.
        See the description of RWORK.

Further Details:
```

```
The orthogonal N-by-N matrix V is obtained as a product of Jacobi
plane rotations. In the case of underflow of the tangent of the
Jacobi angle, a modified Jacobi transformation of Drmac [3] is
used. Pivot strategy uses column interchanges of de Rijk [1]. The
relative accuracy of the computed singular values and the accuracy
of the computed singular vectors (in angle metric) is as guaranteed
by the theory of Demmel and Veselic [2]. The condition number that
determines the accuracy in the full rank case is essentially
min_{D=diag} kappa(A*D), where kappa(.) is the spectral condition
number. The best performance of this Jacobi SVD procedure is
achieved if used in an accelerated version of Drmac and Veselic
[4,5], and it is the kernel routine in the SIGMA library [6]. Some
tunning parameters (marked with [TP]) are available for the
implementer. The computational range for the nonzero singular
values is the machine number interval ( UNDERFLOW , OVERFLOW ). In
extreme cases, even denormalized singular values can be computed
with the corresponding gradual loss of accurate digits.

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgetf2 (M, N, A, LDA, IPIV, INFO)
           CGETF2 computes the LU factorization of a general m-by-n matrix
           using partial pivoting with row interchanges (unblocked algorithm).

Function/Subroutine Documentation
   subroutine cgetf2 (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       CGETF2 computes the LU factorization of a general m-by-n matrix using
       partial pivoting with row interchanges (unblocked algorithm).

Purpose:
   CGETF2 computes an LU factorization of a general m-by-n matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
      A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

 This is the right-looking Level 2 BLAS version of the algorithm.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the m by n matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, U(k,k) is exactly zero. The factorization
        has been completed, but the factor U is exactly
        singular, and division by zero will occur if it is used
        to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgetrf (M, N, A, LDA, IPIV, INFO)
           CGETRF

Function/Subroutine Documentation
   subroutine cgetrf (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       CGETRF

Purpose:
   CGETRF computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
      A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 3 BLAS version of the algorithm.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M-by-N matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
         has been completed, but the factor U is exactly
         singular, and division by zero will occur if it is used
         to solve a system of equations.
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       recursive subroutine cgetrf2 (M, N, A, LDA, IPIV, INFO)
           CGETRF2

Function/Subroutine Documentation
   recursive subroutine cgetrf2 (integer M, integer N, complex, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       CGETRF2

Purpose:
   CGETRF2 computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
      A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

         [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
     A = [ -----|----- ]  with n1 = min(m,n)
         [  A21 | A22  ]       n2 = n-n1

                                           [ A11 ]
   The subroutine calls itself to factor [ --- ],
                                           [ A12 ]
```

```
                  [ A12 ]
   do the swaps on [ --- ], solve A12, update A22,
                  [ A22 ]

   then calls itself to factor A22 and do the swaps on A21.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M-by-N matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
         has been completed, but the factor U is exactly
         singular, and division by zero will occur if it is used
         to solve a system of equations.

SYNOPSIS
   Functions/Subroutines
       subroutine cgetri (N, A, LDA, IPIV, WORK, LWORK, INFO)
           CGETRI

Function/Subroutine Documentation
   subroutine cgetri (integer N, complex, dimension( lda, * ) A, integer LDA,
       integer, dimension( * ) IPIV, complex, dimension( * ) WORK, integer
       LWORK, integer INFO)
       CGETRI

Purpose:
   CGETRI computes the inverse of a matrix using the LU factorization
   computed by CGETRF.

   This method inverts U and then computes inv(A) by solving the system
   inv(A)*L = inv(U) for inv(A).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the factors L and U from the factorization
   A = P*L*U as computed by CGETRF.
```

```
  On exit, if INFO = 0, the inverse of the original matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from CGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimal performance LWORK >= N*NB, where NB is
  the optimal blocksize returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero; the matrix is
        singular and its inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgetrs (TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           CGETRS

Function/Subroutine Documentation
   subroutine cgetrs (character TRANS, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, integer INFO)
       CGETRS

Purpose:
   CGETRS solves a system of linear equations
      A * X = B,  A**T * X = B,  or  A**H * X = B
   with a general N-by-N matrix A using the LU factorization computed
   by CGETRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  The factors L and U from the factorization A = P*L*U
  as computed by CGETRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from CGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine chgeqz (JOB, COMPQ, COMPZ, N, ILO, IHI, H, LDH, T, LDT,
           ALPHA, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, RWORK, INFO)
           CHGEQZ

Function/Subroutine Documentation
   subroutine chgeqz (character JOB, character COMPQ, character COMPZ, integer
       N, integer ILO, integer IHI, complex, dimension( ldh, * ) H, integer
       LDH, complex, dimension( ldt, * ) T, integer LDT, complex, dimension( *
       ) ALPHA, complex, dimension( * ) BETA, complex, dimension( ldq, * ) Q,
       integer LDQ, complex, dimension( ldz, * ) Z, integer LDZ, complex,
       dimension( * ) WORK, integer LWORK, real, dimension( * ) RWORK, integer
       INFO)
       CHGEQZ

Purpose:
   CHGEQZ computes the eigenvalues of a complex matrix pair (H,T),
   where H is an upper Hessenberg matrix and T is upper triangular,
   using the single-shift QZ method.
   Matrix pairs of this type are produced by the reduction to
   generalized upper Hessenberg form of a complex matrix pair (A,B):
```

```
  A = Q1*H*Z1**H,  B = Q1*T*Z1**H,

  as computed by CGGHRD.

  If JOB='S', then the Hessenberg-triangular pair (H,T) is
  also reduced to generalized Schur form,

  H = Q*S*Z**H,  T = Q*P*Z**H,

  where Q and Z are unitary matrices and S and P are upper triangular.

  Optionally, the unitary matrix Q from the generalized Schur
  factorization may be postmultiplied into an input matrix Q1, and the
  unitary matrix Z may be postmultiplied into an input matrix Z1.
  If Q1 and Z1 are the unitary matrices from CGGHRD that reduced
  the matrix pair (A,B) to generalized Hessenberg form, then the output
  matrices Q1*Q and Z1*Z are the unitary factors from the generalized
  Schur factorization of (A,B):

  A = (Q1*Q)*S*(Z1*Z)**H,  B = (Q1*Q)*P*(Z1*Z)**H.

  To avoid overflow, eigenvalues of the matrix pair (H,T)
  (equivalently, of (A,B)) are computed as a pair of complex values
  (alpha,beta).  If beta is nonzero, lambda = alpha / beta is an
  eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)
  A*x = lambda*B*x
  and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the
  alternate form of the GNEP
  mu*A*y = B*y.
  The values of alpha and beta for the i-th eigenvalue can be read
  directly from the generalized Schur form:  alpha = S(i,i),
  beta = P(i,i).

Parameters:

JOB
  JOB is CHARACTER*1
  = 'E': Compute eigenvalues only;
  = 'S': Computer eigenvalues and the Schur form.

COMPQ
  COMPQ is CHARACTER*1
  = 'N': Left Schur vectors (Q) are not computed;
  = 'I': Q is initialized to the unit matrix and the matrix Q
     of left Schur vectors of (H,T) is returned;
  = 'V': Q must contain a unitary matrix Q1 on entry and
     the product Q1*Q is returned.

COMPZ
```

```
  COMPZ is CHARACTER*1
  = 'N': Right Schur vectors (Z) are not computed;
  = 'I': Q is initialized to the unit matrix and the matrix Z
     of right Schur vectors of (H,T) is returned;
  = 'V': Z must contain a unitary matrix Z1 on entry and
     the product Z1*Z is returned.

N
  N is INTEGER
  The order of the matrices H, T, Q, and Z.  N >= 0.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI mark the rows and columns of H which are in
  Hessenberg form.  It is assumed that A is already upper
  triangular in rows and columns 1:ILO-1 and IHI+1:N.
  If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

H
  H is COMPLEX array, dimension (LDH, N)
  On entry, the N-by-N upper Hessenberg matrix H.
  On exit, if JOB = 'S', H contains the upper triangular
  matrix S from the generalized Schur factorization.
  If JOB = 'E', the diagonal of H matches that of S, but
  the rest of H is unspecified.

LDH
  LDH is INTEGER
  The leading dimension of the array H.  LDH >= max( 1, N ).

T
  T is COMPLEX array, dimension (LDT, N)
  On entry, the N-by-N upper triangular matrix T.
  On exit, if JOB = 'S', T contains the upper triangular
  matrix P from the generalized Schur factorization.
  If JOB = 'E', the diagonal of T matches that of P, but
  the rest of T is unspecified.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= max( 1, N ).

ALPHA
  ALPHA is COMPLEX array, dimension (N)
  The complex scalars alpha that define the eigenvalues of
  GNEP.  ALPHA(i) = S(i,i) in the generalized Schur factorization.
```

```
BETA
  BETA is COMPLEX array, dimension (N)
  The real non-negative scalars beta that define the
  eigenvalues of GNEP.  BETA(i) = P(i,i) in the generalized
  Schur factorization.

  Together, the quantities alpha = ALPHA(j) and beta = BETA(j)
  represent the j-th eigenvalue of the matrix pair (A,B), in
  one of the forms lambda = alpha/beta or mu = beta/alpha.
  Since either lambda or mu may overflow, they should not,
  in general, be computed.

Q
  Q is COMPLEX array, dimension (LDQ, N)
  On entry, if COMPZ = 'V', the unitary matrix Q1 used in the
  reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the unitary matrix of left Schur
  vectors of (H,T), and if COMPZ = 'V', the unitary matrix of
  left Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.  LDQ >= 1.
  If COMPQ='V' or 'I', then LDQ >= N.

Z
  Z is COMPLEX array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the unitary matrix Z1 used in the
  reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the unitary matrix of right Schur
  vectors of (H,T), and if COMPZ = 'V', the unitary matrix of
  right Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1.
  If COMPZ='V' or 'I', then LDZ >= N.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
```

```
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1,...,N: the QZ iteration did not converge.  (H,T) is not
     in Schur form, but ALPHA(i) and BETA(i),
     i=INFO+1,...,N should be correct.
  = N+1,...,2*N: the shift calculation failed.  (H,T) is not
     in Schur form, but ALPHA(i) and BETA(i),
     i=INFO-N+1,...,N should be correct.

  We assume that complex ABS works as long as its value is less than
  overflow.
```
