SIG ==> with

makeFR : FinalFact -> Factored UP
++ makeFR(flist) turns the final factorization of henselFact into a
++ \spadtype{Factored} object.

degreePartition : DDLlist -> Multiset N
++ degreePartition(ddfactorization) returns the degree partition of
++ the polynomial f modulo p where ddfactorization is the distinct
++ degree factorization of f computed by ddFact for some prime p.

musserTrials : () -> P
++ musserTrials() returns the number of primes that are tried in
++ \spadfun{modularFactor}.

musserTrials : P -> P
++ musserTrials(n) sets to n the number of primes to be tried in
++ \spadfun{modularFactor} and returns the previous value.

stopMusserTrials : () -> P
++ stopMusserTrials() returns the bound on the number of factors for
++ which \spadfun{modularFactor} stops to look for an other prime. You
++ will have to remember that the step of recombining the extraneous
++ factors may take up to \spad{2**stopMusserTrials()} trials.

stopMusserTrials : P -> P
++ stopMusserTrials(n) sets to n the bound on the number of factors for
++ which \spadfun{modularFactor} stops to look for an other prime. You
++ will have to remember that the step of recombining the extraneous
++ factors may take up to \spad{2**n} trials. Returns the previous
++ value.

numberOfFactors : DDLlist -> N
++ numberOfFactors(ddfactorization) returns the number of factors of
++ the polynomial f modulo p where ddfactorization is the distinct
++ degree factorization of f computed by ddFact for some prime p.

modularFactor : UP -> MFact
++ modularFactor(f) chooses a "good" prime and returns the factorization
++ of f modulo this prime in a form that may be used by
++ completeHensel. If prime is zero

```

```

++ it means that f has been proved to be irreducible over the integers
++ or that f is a unit (1 or -1).
++ f shall be primitive (content(p)=1) and square free
++ (without repeated factors).

useSingleFactorBound? : () -> Boolean
++ useSingleFactorBound?() returns \spad{true} if algorithm with single
++ factor bound is used for factorization, \spad{false} for algorithm
++ with overall bound.

useSingleFactorBound : Boolean -> Boolean
++ useSingleFactorBound(b) chooses the algorithm to be used by the
++ factorizers: \spad{true} for algorithm with single
++ factor bound, \spad{false} for algorithm with overall bound.
++ Returns the previous value.

useEisensteinCriterion? : () -> Boolean
++ useEisensteinCriterion?() returns \spad{true} if factorizers
++ check Eisenstein's criterion before factoring.

useEisensteinCriterion : Boolean -> Boolean
++ useEisensteinCriterion(b) chooses whether factorizers check
++ Eisenstein's criterion before factoring: \spad{true} for
++ using it, \spad{false} else. Returns the previous value.

eisensteinIrreducible? : UP -> Boolean
++ eisensteinIrreducible?(p) returns \spad{true} if p can be
++ shown to be irreducible by Eisenstein's criterion,
++ \spad{false} is inconclusive.

tryFunctionalDecomposition? : () -> Boolean
++ tryFunctionalDecomposition?() returns \spad{true} if
++ factorizers try functional decomposition of polynomials before
++ factoring them.

tryFunctionalDecomposition : Boolean -> Boolean
++ tryFunctionalDecomposition(b) chooses whether factorizers have
++ to look for functional decomposition of polynomials
++ (\spad{true}) or not (\spad{false}). Returns the previous value.

factor : UP -> Factored UP
++ factor(p) returns the factorization of p over the integers.

factor : (UP,N) -> Factored UP
++ factor(p,r) factorizes the polynomial p using the single factor bound
++ algorithm and knowing that p has at least r factors.

factor : (UP,List N) -> Factored UP
++ factor(p,listOfDegrees) factorizes the polynomial p using the single
++ factor bound algorithm and knowing that p has for possible

```

```

    ++ splitting of its degree listOfDegrees.

factor : (UP,List N,N) -> Factored UP
    ++ factor(p,listOfDegrees,r) factorizes the polynomial p using the single
    ++ factor bound algorithm, knowing that p has for possible
    ++ splitting of its degree listOfDegrees and that p has at least r
    ++ factors.

factor : (UP,N,N) -> Factored UP
    ++ factor(p,d,r) factorizes the polynomial p using the single
    ++ factor bound algorithm, knowing that d divides the degree of all
    ++ factors of p and that p has at least r factors.

factorSquareFree : UP -> Factored UP
    ++ factorSquareFree(p) returns the factorization of p which is supposed
    ++ not having any repeated factor (this is not checked).

factorSquareFree : (UP,N) -> Factored UP
    ++ factorSquareFree(p,r) factorizes the polynomial p using the single
    ++ factor bound algorithm and knowing that p has at least r factors.
    ++ f is supposed not having any repeated factor (this is not checked).

factorSquareFree : (UP,List N) -> Factored UP
    ++ factorSquareFree(p,listOfDegrees) factorizes the polynomial p using
    ++ the single factor bound algorithm and knowing that p has for possible
    ++ splitting of its degree listOfDegrees.
    ++ f is supposed not having any repeated factor (this is not checked).

factorSquareFree : (UP,List N,N) -> Factored UP
    ++ factorSquareFree(p,listOfDegrees,r) factorizes the polynomial p using
    ++ the single factor bound algorithm, knowing that p has for possible
    ++ splitting of its degree listOfDegrees and that p has at least r
    ++ factors.
    ++ f is supposed not having any repeated factor (this is not checked).

factorSquareFree : (UP,N,N) -> Factored UP
    ++ factorSquareFree(p,d,r) factorizes the polynomial p using the single
    ++ factor bound algorithm, knowing that d divides the degree of all
    ++ factors of p and that p has at least r factors.
    ++ f is supposed not having any repeated factor (this is not checked).

factorOfDegree : (P,UP) -> Union(UP,"failed")
    ++ factorOfDegree(d,p) returns a factor of p of degree d.

factorOfDegree : (P,UP,N) -> Union(UP,"failed")
    ++ factorOfDegree(d,p,r) returns a factor of p of degree
    ++ d knowing that p has at least r factors.

factorOfDegree : (P,UP,List N) -> Union(UP,"failed")
    ++ factorOfDegree(d,p,listOfDegrees) returns a factor

```

```

++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees.

factorOfDegree : (P,UP,List N,N) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees,r) returns a factor
++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees, and that p has at least r factors.

factorOfDegree : (P,UP,List N,N,Boolean) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees,r,sqf) returns a
++ factor of p of degree d knowing that p has for possible splitting of
++ its degree listOfDegrees, and that p has at least r factors.
++ If \spad{sqf=true} the polynomial is assumed to be square free
++ (without repeated factors).

henselFact : (UP,Boolean) -> FinalFact
++ henselFact(p,sqf) returns the factorization of p, the result
++ is a Record such that \spad{contp=}content p,
++ \spad{factors=}List of irreducible factors of p with exponent.
++ If \spad{sqf=true} the polynomial is assumed to be square free
++ (without repeated factors).

btwFact : (UP,Boolean,Set N,N) -> FinalFact
++ btwFact(p,sqf,pd,r) returns the factorization of p, the result
++ is a Record such that \spad{contp=}content p,
++ \spad{factors=}List of irreducible factors of p with exponent.
++ If \spad{sqf=true} the polynomial is assumed to be square free
++ (without repeated factors).
++ pd is the \spadtype{Set} of possible degrees. r is a lower bound for
++ the number of factors of p. Please do not use this function in your
++ code because its design may change.

PackPoly   ==> PackageForPoly(K, PolyRing, E, #symb)

SIG ==> with

    reset : () -> Void

```

```

setCurve : PolyRing -> PolyRing
  ++ setCurve sets the defining polynomial

homogenize : (PolyRing,Integer) -> PolyRing

printInfo : List Boolean -> Void
  ++ printInfo(lbool) prints some information coming from various
  ++ package and domain used by this package.

theCurve : () -> PolyRing
  ++ theCurve returns the specified polynomial for the package.

genus : () -> NNI
  ++ genus returns the genus of the curve defined by the polynomial
  ++ given to the package.

genusNeg : () -> INT

desingTree : () -> List DesTree
  ++ desingTree returns the desingularisation trees at all singular
  ++ points of the curve defined by the polynomial given to the package.

desingTreeWoFullParam : () -> List DesTree
  ++ desingTreeWoFullParam returns the desingularisation trees at all
  ++ singular points of the curve defined by the polynomial given to
  ++ the package. The local parametrizations are not computed.

setSingularPoints : List ProjPt -> List ProjPt
  ++ setSingularPoints(lpt) sets the singular points to be used.
  ++ Beware: no attempt is made to check if the points are singular
  ++ or not, nor if all of the singular points are presents. Hence,
  ++ results of some computation maybe false. It is intend to be use
  ++ when one want to compute the singular points are computed by other
  ++ means than to use the function singularPoints.

singularPoints : () -> List(ProjPt)
  ++ singularPoints() returns the singular points of the
  ++ curve defined by the polynomial given to the package.
  ++ If the singular points lie in an extension of the specified ground
  ++ field an error message is issued specifying the extension degree
  ++ needed to find all singular points.

parametrize : (PolyRing,Plc) -> PCS
  ++ parametrize(f,pl) returns a local parametrization of f at the place
  ++ pl.

lBasis : DIVISOR -> Record(num:List PolyRing, den: PolyRing)
  ++ lBasis computes a basis associated to the specified divisor

```

```

findOrderOfDivisor : (DIVISOR,Integer,Integer) -> _
    Record(ord:Integer,num:PolyRing,den:PolyRing,upTo:Integer)

interpolateForms : (DIVISOR,NNI) -> List(PolyRing)
    ++ interpolateForms(d,n) returns a basis of the interpolate forms of
    ++ degree n of the divisor d.

interpolateFormsForFact : (DIVISOR,List PolyRing) -> List(PolyRing)

eval : (PolyRing,Plc) -> K
    ++ eval(f,pl) evaluate f at the place pl.

eval : (PolyRing,PolyRing,Plc) -> K
    ++ eval(f,g,pl) evaluate the function f/g at the place pl.

eval : (FRACPOLY,Plc) -> K
    ++ eval(u,pl) evaluate the function u at the place pl.

evalIfCan : (PolyRing,Plc) -> Union(K,"failed")
    ++ evalIfCan(f,pl) evaluate f at the place pl
    ++ (returns "failed" if it is a pole).

evalIfCan : (PolyRing,PolyRing,Plc) -> Union(K,"failed")
    ++ evalIfCan(f,g,pl) evaluate the function f/g at the place pl
    ++ (returns "failed" if it is a pole).

evalIfCan : (FRACPOLY,Plc) -> Union(K,"failed")
    ++ evalIfCan(u,pl) evaluate the function u at the place pl
    ++ (returns "failed" if it is a pole).

intersectionDivisor : PolyRing -> DIVISOR
    ++ intersectionDivisor(pol) compute the intersection divisor
    ++ (the Cartier divisor) of the form pol with the curve. If some
    ++ intersection points lie in an extension of the ground field,
    ++ an error message is issued specifying the extension degree
    ++ needed to find all the intersection points.
    ++ (If pol is not homogeneous an error message is issued).

adjunctionDivisor : () -> DIVISOR
    ++ adjunctionDivisor computes the adjunction divisor of the plane
    ++ curve given by the polynomial crv.

placesAbove : ProjPt -> List Plc

pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

if K has Finite then --should we say LocallyAlgebraicallyClosedField??

```

```

rationalPlaces : () -> List Plc
  ++ rationalPlaces returns all the rational places of the
  ++ curve defined by the polynomial given to the package.

rationalPoints : () -> List(ProjPt)

LPolynomial : () -> SparseUnivariatePolynomial Integer
  ++ LPolynomial() returns the L-Polynomial of the curve.

LPolynomial : PI -> SparseUnivariatePolynomial Integer
  ++ LPolynomial(d) returns the L-Polynomial of the curve in
  ++ constant field extension of degree d.

classNumber : () -> Integer
  ++ classNumber() returns the class number of the curve.

placesOfDegree : PI -> List Plc
  ++ placesOfDegree(d) returns all places of degree d of the
  ++ curve.

numberOfPlacesOfDegree : PI -> Integer
  ++ numberOfPlacesOfDegree(pi) returns the number of places
  ++ of the given degree

numberRatPlacesExtDeg : PI -> Integer
  ++ numberRatPlacesExtDeg(n) returns the number of rational
  ++ places in the constant field extension of degree n

numberPlacesDegExtDeg : (PI, PI) -> Integer
  ++ numberPlacesDegExtDeg(d, n) returns the number of
  ++ places of degree d in the constant field extension of
  ++ degree n

ZetaFunction : () -> UTSZ
  ++ ZetaFunction() returns the Zeta function of the curve.
  ++ Calculated by using the L-Polynomial

ZetaFunction : PI -> UTSZ
  ++ ZetaFunction(pi) returns the Zeta function of the curve in
  ++ constant field extension. Calculated by using the L-Polynomial

=====

GenExEuclid examples

=====

The equation $Af+Bg=h$ and its generalization to n polynomials is solved for solutions over the R , euclidean domain.

A table containing the solutions of $Af+Bg=x**k$ is used.

The operations are performed modulus a prime which are in principle big enough, but the solutions are tested and, in case of failure, a hensel lifting process is used to get to the right solutions. It will be used in the factorization of multivariate polynomials over finite field, with $R=F[x]$.

— package **GENEEZ GenExEuclid** —

```

)abbrev package GENEEZ GenExEuclid
++ Author : P.Gianni.
++ Date Created: January 1990
++ Description:

GenExEuclid(R,BP) : SIG == CODE where
  R : EuclideanDomain
  BP : UnivariatePolynomialCategory R

PI ==> PositiveInteger
NNI ==> NonNegativeInteger
L ==> List

SIG ==> with

reduction : (BP,R) -> BP
++ reduction(p,prime) reduces the polynomial p modulo prime of R.
++ Note that this function is exported only because it's conditional.

compBound : (BP,L BP) -> NNI
++ compBound(p,lp)
++ computes a bound for the coefficients of the solution
++ polynomials.
++ Given a polynomial right hand side p,
++ and a list lp of left hand side polynomials.
++ Exported because it depends on the valuation.

```

```

tablePow : (NNI,R,L BP) -> Union(Vector(L BP),"failed")
++ tablePow(maxdeg,prime,lpol) constructs the table with the
++ coefficients of the Extended Euclidean Algorithm for lpol.
++ Here the right side is  $\mathbb{Z}/p\mathbb{Z}[x^k]$ , for k less or equal to maxdeg.
++ The operation returns "failed" when the elements
++ are not coprime modulo prime.

solveid : (BP,R,Vector L BP) -> Union(L BP,"failed")
++ solveid(h,table) computes the coefficients of the
++ extended euclidean algorithm for a list of polynomials
++ whose tablePow is table and with right side h.

testModulus : (R, L BP) -> Boolean
++ testModulus(p,lp) returns true if the the prime p
++ is valid for the list of polynomials lp, preserves
++ the degree and they remain relatively prime.

CODE ==> add

Rationalization of several types of genus 0 integrands;
 This internal package rationalises integrands on curves of the form:

$$\begin{aligned} y^2 &= a x^2 + b x + c \\ y^2 &= (a x + b) / (c x + d) \\ f(x, y) &= 0 \text{ where } f \text{ has degree 1 in } x \end{aligned}$$

The rationalization is done for integration, limited integration,
 extended integration and the risch differential equation;

— Graphviz.help —

```
=====
Graphviz examples
=====
```

Graphviz dot files have a header which might look like

```
digraph graphname {
  graph [rankdir="LR" ranksep="3.0"]
  node [style=filled];
  edge [penwidth="0.5" color="blue"];
```

This default header can be created using 'standardDotHeader()'

```
header:=standardDotHeader()
```

A graph is the body of the dot file containing information about what the nodes are and how they are connected. It might contain node information such as

```
I1 [fillcolor="white"];
N1 [fillcolor="cadetblue"];
```

and line information such as

```
I1 -> N1 [color="red" penwidth="3"];
```

A sample graph can be created using 'sampleDotGraph()'

```
graph:=sampleDotGraph()
```

Once the header and graph information is created we can write that information into a file using the function 'writeDotGraph'. Two things to note are

- * a trailing '}' line is automatically added
- * the supplied name adds the ".dot" extension

```
writeDotGraph(header,graph,"NeuralNet")
```

will create the file "NeuralNet.dot"

The "NeuralNet.dot" file can be graphed and stored in an encapsulated postscript (.eps) format with

```
dot2eps "NeuralNet"
```

will create the file "NeuralNet.eps"

You can call a viewer on your platform.

Linux has 'evince'. MAC has 'gv'. MAC has 'open'.

Most places have 'firefox'

```
dotview("evince","NeuralNet")
```

++     Computer Science Press, 1985.
++ Description:
++ GrayCode provides a function for efficiently running
++ through all subsets of a finite set, only changing one element
++ by another one.
  
```

GrayCode() : SIG == CODE where

```

PI ==> PositiveInteger
I  ==> Integer
V  ==> Vector
  
```

SIG ==> with

```

nextSubsetGray : (V V I,PI) -> V V I
  
```

```

++ nextSubsetGray(ww,n) returns a vector vv whose components
++ have the following meanings:\br
++ vv.1: a vector of length n whose entries are 0 or 1. This
++ can be interpreted as a code for a subset of the set 1,...,n;
++ vv.1 differs from ww.1 by exactly one entry;\br
++ vv.2.1 is the number of the entry of vv.1 which
++ will be changed next time;\br
++ vv.2.1 = n+1 means that vv.1 is the last subset;
++ trying to compute nextSubsetGray(vv) if vv.2.1 = n+1
++ will produce an error!\br
++
++ The other components of vv.2 are needed to compute
++ nextSubsetGray efficiently.
++ Note that this is an implementation of [Williamson, Topic II, 3.54,
++ p. 112] for the special case  $r_1 = r_2 = \dots = r_n = 2$ ;
++ Note that nextSubsetGray produces a side-effect,
++ nextSubsetGray(vv) and  $vv := \text{nextSubsetGray}(vv)$ 
++ will have the same effect.

```

```

firstSubsetGray : PI -> V V I
++ firstSubsetGray(n) creates the first vector ww to start a
++ loop using nextSubsetGray(ww,n)

```

CODE ==> add

```

firstSubsetGray(n : PI) ==

=====

GroebnerFactorizationPackage examples

=====

GroebnerFactorizationPackage provides the function "groebnerFactor" which uses the factorization routines of Axiom to factor each polynomial under consideration while doing the groebner basis algorithm. Then it writes the ideal as an intersection of ideals determined by the irreducible factors. Note that the whole ring may occur as well as other redundancies. We also use the fact, that from the second factor on we can assume that the preceding factors are not equal to 0 and we divide all polynomials under considerations by the elements of this list of "nonZeroRestrictions".

The result is a list of groebner bases, whose union of solutions of the corresponding systems of equations is the solution of the system of equation corresponding to the input list. The term ordering is determined by the polynomial type used.

Suggested types include

- * DistributedMultivariatePolynomial
- * HomogeneousDistributedMultivariatePolynomial
- * GeneralDistributedMultivariatePolynomial

Solving systems of polynomial equations with the Groebner basis algorithm can often be very time consuming because, in general, the algorithm has exponential run-time. These systems, which often come from concrete applications, frequently have symmetries which are not taken advantage of by the algorithm. However, it often happens in this case that the polynomials which occur during the Groebner calculations are reducible. Since Axiom has an excellent polynomial factorization algorithm, it is very natural to combine the Groebner and factorization algorithms.

GroebnerFactorizationPackage exports the groebnerFactorize operation which implements a modified Groebner basis algorithm. In this algorithm, each polynomial that is to be put into the partial list of the basis is first factored. The remaining calculation is split into as many parts as there are irreducible factors. Call these factors $p_1, \dots, p_N$. In the branches corresponding to $p_2, \dots, p_N$, the factor p_1 can be divided out, and so on. This package also contains operations that allow you to specify the polynomials that are not zero on the common roots of the final Groebner basis.

Here is an example from chemistry. In a theoretical model of the cyclohexan C_6H_{12} , the six carbon atoms each sit in the center of gravity of a tetrahedron that has two hydrogen atoms and two carbon atoms at its corners. We first normalize and set the length of each edge to 1. Hence, the distances of one fixed carbon atom to each of its immediate neighbours is 1. We will denote the distances to the other three carbon atoms by x , y and z .

A. Dress developed a theory to decide whether a set of points and distances between them can be realized in an n -dimensional space. Here, of course, we have $n = 3$.

```
mfzn : SQMATRIX(6,DMP([x,y,z],Fraction INT)) := _
[ [0,1,1,1,1,1], [1,0,1,8/3,x,8/3], [1,1,0,1,8/3,y], _
  [1,8/3,1,0,1,8/3], [1,x,8/3,1,0,1], [1,8/3,y,8/3,1,0] ]
+0 1 1 1 1 1+
|
|      8      8|
|1 0 1 - x -|
|      3      3|
|
|      8      |
|1 1 0 1 - y|
|      3      |
|
|      8      8|
|1 - 1 0 1 -|
|      3      3|
|
|      8      |
|1 x - 1 0 1|
|      3      |
|
|      8      8|
|1 - y - 1 0|
+ 3      3 +
```

```
Type: SquareMatrix(6,DistributedMultivariatePolynomial([x,y,z],
  Fraction Integer))
```

For the cyclohexan, the distances have to satisfy this equation.

```

eq := determinant mfn
      2 2 22 2 25 2 22 2 388 250 25 2 250 14575
    - x y + -- x y - -- x + -- x y - --- x y - --- x - -- y - --- y + -----
      3      9      3      9      27      9      27      81
Type: DistributedMultivariatePolynomial([x,y,z],Fraction Integer)

```

They also must satisfy the equations given by cyclic shifts of the indeterminates.

```

    [x - --, y + -, z + -]]
      3 3 3
Type: List List DistributedMultivariatePolynomial([x,y,z],Fraction Integer)

```

The union of the solutions of this list is the solution of our original problem. If we impose positivity conditions, we get two relevant ideals. One ideal is zero-dimensional, namely $x = y = z = 11/3$, and this determines the "boat" form of the cyclohexan. The other ideal is one-dimensional, which means that we have a solution space given by one parameter. This gives the "chair" form of the cyclohexan. The parameter describes the angle of the "back of the chair."

groebnerFactorize has an optional Boolean-valued second argument. When it is true partial results are displayed, since it may happen that the calculation does not terminate in a reasonable time. See the source code for GroebnerFactorizationPackage in groebf.spad.pamphlet for more details about the algorithms used.

++ newPairs(lp, p) constructs list of critical pairs from the list of
++ lp of input polynomials and a given further one p.
++ It uses criteria M and T to reduce the list.
newPairs : (L sugarPol, Dpol) -> L critPair

++ updateCritPairs(lcP1,lcP2,p) applies criterion B to lcP1 using
++ p. Then this list is merged with lcP2.
updateCritPairs : (L critPair, L critPair, Dpol) -> L critPair

++ updateBasis(li,p,deg) every polynomial in li is dropped if
++ its leading term is a multiple of the leading term of p.
++ The result is this list enlarged by p.
updateBasis : (L sugarPol, Dpol, NNI) -> L sugarPol

```

```

++ createGroebnerBases(basis, redPolys, nonZeroRestrictions, inputPolys,
++   lcP,listOfBases): This function is used to be called from
++   groebnerFactorize.
++ basis: part of a Groebner basis, computed so far
++ redPolys: Polynomials from the ideal to be used for reducing,
++   we don't throw away polynomials
++ nonZeroRestrictions: polynomials not zero in the common zeros
++   of the polynomials in the final (Groebner) basis
++ inputPolys: assumed to be in descending order
++ lcP: list of critical pairs built from polynomials of the
++   actual basis
++ listOfBases: Collects the (Groebner) bases constructed by this
++   recursive algorithm at different stages.
++   we print info messages if info is true

=====

GroebnerPackage examples

=====

GroebnerPackage computes groebner bases for polynomial ideals. The basic computation provides a distinguished set of generators for polynomial ideals over fields. This basis allows an easy test for membership: the operation normalForm returns zero on ideal members. When the provided coefficient domain, Dom, is not a field, the result is equivalent to considering the extended ideal with Fraction(Dom) as coefficients, but considerably more efficient since all calculations are performed in Dom.

Additional arguments "info" and "redcrit" can be given to provide incremental information during computation.

Argument "info" produces a computational summary for each s-polynomial. Argument "redcrit" prints out the reduced critical pairs.

The term ordering is determined by the polynomial type used.

Suggested types include

- * DistributedMultivariatePolynomial
- * HomogeneousDistributedMultivariatePolynomial
- * GeneralDistributedMultivariatePolynomial

Example to call groebner:

```
s1:DMP[w,p,z,t,s,b]RN:= 45*p + 35*s - 165*b - 36
```

```

s2:DMP[w,p,z,t,s,b]RN:= 35*p + 40*z + 25*t - 27*s
s3:DMP[w,p,z,t,s,b]RN:= 15*w + 25*p*s + 30*z - 18*t - 165*b**2
s4:DMP[w,p,z,t,s,b]RN:= -9*w + 15*p*t + 20*z*s
s5:DMP[w,p,z,t,s,b]RN:= w*p + 2*z*t - 11*b**3
s6:DMP[w,p,z,t,s,b]RN:= 99*w - 11*b*s + 3*b**2
s7:DMP[w,p,z,t,s,b]RN:= b**2 + 33/50*b + 2673/10000

```

```
sn7:=[s1,s2,s3,s4,s5,s6,s7]
```

```
groebner(sn7,info)
```

groebner calculates a minimal Groebner Basis
all reductions are TOTAL reductions

To get the reduced critical pairs do:

```
groebner(sn7,"redcrit")
```

You can get other information by calling:

```
groebner(sn7,"info")
```

which returns:

```

ci => Leading monomial for critpair calculation
tci => Number of terms of polynomial i
cj => Leading monomial for critpair calculation
tcj => Number of terms of polynomial j
c => Leading monomial of critpair polynomial
tc => Number of terms of critpair polynomial
rc => Leading monomial of redcritpair polynomial
trc => Number of terms of redcritpair polynomial
tF => Number of polynomials in reduction list F
tD => Number of critpairs still to do

```

We can compute the remainder of f on division by g and h:

```
f:HDMP([x,y],FRAC INT) := x^3 + 3*y^2
```

```
g:HDMP([x,y],FRAC INT) := x^2 + y
```

```
h:HDMP([x,y],FRAC INT) := x + 2*x*j
```

```
normalForm(f,[g,h])
```

```
Lex := DMP([x,y],FRAC INT)
```

```
normalForm(f::Lex,[g::Lex,h::Lex])
```

++ Description:
++ Solve systems of polynomial equations using Groebner bases
++ Total order Groebner bases are computed and then converted to lex ones
++ This package is mostly intended for internal use.

GroebnerSolve(lv,F,R) : SIG == CODE where
  R : GcdDomain
  F : GcdDomain
  lv : List Symbol

NNI    ==> NonNegativeInteger
I      ==> Integer
S      ==> Symbol
OV     ==> OrderedVariableList(lv)
IES    ==> IndexedExponents Symbol
DP     ==> DirectProduct(#lv,NonNegativeInteger)
DPoly  ==> DistributedMultivariatePolynomial(lv,F)
HDP    ==> HomogeneousDirectProduct(#lv,NonNegativeInteger)
HDPoly ==> HomogeneousDistributedMultivariatePolynomial(lv,F)
SUP    ==> SparseUnivariatePolynomial(DPoly)
L      ==> List
P      ==> Polynomial

SIG ==> with

  groebSolve : (L DPoly,L OV) -> L L DPoly
  ++ groebSolve(lp,lv) reduces the polynomial system lp in variables lv
  ++ to triangular form. Algorithm based on groebner bases algorithm
  ++ with linear algebra for change of ordering.
  ++ Preprocessing for the general solver.
  ++ The polynomials in input are of type \spadtype{DMP}.

  testDim : (L HDPoly,L OV) -> Union(L HDPoly,"failed")
  ++ testDim(lp,lv) tests if the polynomial system lp
  ++ in variables lv is zero dimensional.

  genericPosition : (L DPoly, L OV) -> Record(dpolys:L DPoly, coords: L I)
  ++ genericPosition(lp,lv) puts a radical zero dimensional ideal
  ++ in general position, for system lp in variables lv.

=====
Guess examples
=====

```

The packages defined in this file enable {Axiom} to guess formulas for sequences of, for example, rational numbers or rational functions, given the first few terms. It extends and complements Christian Krattenthaler's program Rate and the relevant parts of Bruno Salvy and Paul Zimmermann's GFUN.

This package implements guessing of sequences. Packages for the most common cases are provided as `GuessInteger`, `GuessPolynomial`, etc.

guess : List F -> GUESSRESULT
++ \spad{guess l} applies recursively \spadfun{guessRec} and
++ \spadfun{guessADE} to the successive differences and quotients of
++ the list. Default options as described in
++ \spadtype{GuessOptionFunctions0} are used.

```

```

guess : (List F, LGOPT) -> GUESSRESULT
++ \spad{guess(l, options)} applies recursively \spadfun{guessRec}
++ and \spadfun{guessADE} to the successive differences and quotients
++ of the list. The given options are used.

guess : (List F, List GUESSER, List Symbol) -> GUESSRESULT
++ \spad{guess(l, guessers, ops)} applies recursively the given
++ guessers to the successive differences if ops contains the symbol
++ guessSum and quotients if ops contains the symbol guessProduct to
++ the list. Default options as described in
++ \spadtype{GuessOptionFunctions0} are used.

guess : (List F, List GUESSER, List Symbol, LGOPT) -> GUESSRESULT
++ \spad{guess(l, guessers, ops)} applies recursively the given
++ guessers to the successive differences if ops contains the symbol
++ \spad{guessSum} and quotients if ops contains the symbol
++ \spad{guessProduct} to the list. The given options are used.

guessExpRat : List F -> GUESSRESULT
++ \spad{guessExpRat l} tries to find a function of the form
++  $n \mapsto (a+b n)^n r(n)$ , where  $r(n)$  is a rational function, that fits
++ l.

guessExpRat : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessExpRat(l, options)} tries to find a function of the
++ form  $n \mapsto (a+b n)^n r(n)$ , where  $r(n)$  is a rational function, that
++ fits l.

guessBinRat : List F -> GUESSRESULT
++ \spad{guessBinRat(l, options)} tries to find a function of the
++ form  $n \mapsto \text{binomial}(a+b n, n) r(n)$ , where  $r(n)$  is a rational
++ function, that fits l.

guessBinRat : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessBinRat(l, options)} tries to find a function of the
++ form  $n \mapsto \text{binomial}(a+b n, n) r(n)$ , where  $r(n)$  is a rational
++ function, that fits l.

if F has RetractableTo Symbol and S has RetractableTo Symbol then

guessExpRat : Symbol -> GUESSER
++ \spad{guessExpRat q} returns a guesser that tries to find a
++ function of the form  $n \mapsto (a+b q^n)^n r(q^n)$ , where  $r(q^n)$  is a
++ q-rational function, that fits l.

guessBinRat : Symbol -> GUESSER
++ \spad{guessBinRat q} returns a guesser that tries to find a
++ function of the form  $n \mapsto q \text{binomial}(a+b n, n) r(n)$ , where  $r(q^n)$  is a
++ q-rational function, that fits l.

```

```

guessHP : (LGOPT -> HPSPEC) -> GUESSER
++ \spad{guessHP f} constructs an operation that applies Hermite-Pade
++ approximation to the series generated by the given function f.

guessADE : List F -> GUESSRESULT
++ \spad{guessADE l} tries to find an algebraic differential equation
++ for a generating function whose first Taylor coefficients are
++ given by l, using the default options described in
++ \spadtype{GuessOptionFunctions0}.

guessADE : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessADE(l, options)} tries to find an algebraic
++ differential equation for a generating function whose first Taylor
++ coefficients are given by l, using the given options.

guessAlg : List F -> GUESSRESULT
++ \spad{guessAlg l} tries to find an algebraic equation for a
++ generating function whose first Taylor coefficients are given by
++ l, using the default options described in
++ \spadtype{GuessOptionFunctions0}. It is equivalent to
++ \spadfun{guessADE}(l, maxDerivative == 0).

guessAlg : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessAlg(l, options)} tries to find an algebraic equation
++ for a generating function whose first Taylor coefficients are
++ given by l, using the given options. It is equivalent to
++ \spadfun{guessADE}(l, options) with \spad{maxDerivative == 0}.

guessHolo : List F -> GUESSRESULT
++ \spad{guessHolo l} tries to find an ordinary linear differential
++ equation for a generating function whose first Taylor coefficients
++ are given by l, using the default options described in
++ \spadtype{GuessOptionFunctions0}. It is equivalent to
++ \spadfun{guessADE}\spad{(l, maxPower == 1)}.

guessHolo : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessHolo(l, options)} tries to find an ordinary linear
++ differential equation for a generating function whose first Taylor
++ coefficients are given by l, using the given options. It is
++ equivalent to \spadfun{guessADE}\spad{(l, options)} with
++ \spad{maxPower == 1}.

guessPade : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessPade(l, options)} tries to find a rational function
++ whose first Taylor coefficients are given by l, using the given
++ options. It is equivalent to \spadfun{guessADE}\spad{(l,
++ maxDerivative == 0, maxPower == 1, allDegrees == true)}.

```

++ q-rational function, that fits l.

```

guessHP : (LGOPT -> HPSPEC) -> GUESSER
++ \spad{guessHP f} constructs an operation that applies Hermite-Pade
++ approximation to the series generated by the given function f.

guessADE : List F -> GUESSRESULT
++ \spad{guessADE l} tries to find an algebraic differential equation
++ for a generating function whose first Taylor coefficients are
++ given by l, using the default options described in
++ \spadtype{GuessOptionFunctions0}.

guessADE : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessADE(l, options)} tries to find an algebraic
++ differential equation for a generating function whose first Taylor
++ coefficients are given by l, using the given options.

guessAlg : List F -> GUESSRESULT
++ \spad{guessAlg l} tries to find an algebraic equation for a
++ generating function whose first Taylor coefficients are given by
++ l, using the default options described in
++ \spadtype{GuessOptionFunctions0}. It is equivalent to
++ \spadfun{guessADE}(l, maxDerivative == 0).

guessAlg : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessAlg(l, options)} tries to find an algebraic equation
++ for a generating function whose first Taylor coefficients are
++ given by l, using the given options. It is equivalent to
++ \spadfun{guessADE}(l, options) with \spad{maxDerivative == 0}.

guessHolo : List F -> GUESSRESULT
++ \spad{guessHolo l} tries to find an ordinary linear differential
++ equation for a generating function whose first Taylor coefficients
++ are given by l, using the default options described in
++ \spadtype{GuessOptionFunctions0}. It is equivalent to
++ \spadfun{guessADE}\spad{(l, maxPower == 1)}.

guessHolo : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessHolo(l, options)} tries to find an ordinary linear
++ differential equation for a generating function whose first Taylor
++ coefficients are given by l, using the given options. It is
++ equivalent to \spadfun{guessADE}\spad{(l, options)} with
++ \spad{maxPower == 1}.

guessPade : (List F, LGOPT) -> GUESSRESULT
++ \spad{guessPade(l, options)} tries to find a rational function
++ whose first Taylor coefficients are given by l, using the given
++ options. It is equivalent to \spadfun{guessADE}\spad{(l,

```

```

    ++ maxDerivative == 0, maxPower == 1, allDegrees == true)}.

guessPade : List F -> GUESSRESULT
    ++ \spad{guessPade(l, options)} tries to find a rational function
    ++ whose first Taylor coefficients are given by l, using the default
    ++ options described in \spadtype{GuessOptionFunctions0}. It is
    ++ equivalent to \spadfun{guessADE}\spad{(l, options)} with
    ++ \spad{maxDerivative == 0, maxPower == 1, allDegrees == true}.

guessRec : List F -> GUESSRESULT
    ++ \spad{guessRec l} tries to find an ordinary difference equation
    ++ whose first values are given by l, using the default options
    ++ described in \spadtype{GuessOptionFunctions0}.

guessRec : (List F, LGOPT) -> GUESSRESULT
    ++ \spad{guessRec(l, options)} tries to find an ordinary difference
    ++ equation whose first values are given by l, using the given
    ++ options.

guessPRec : (List F, LGOPT) -> GUESSRESULT
    ++ \spad{guessPRec(l, options)} tries to find a linear recurrence
    ++ with polynomial coefficients whose first values are given by l,
    ++ using the given options. It is equivalent to
    ++ \spadfun{guessRec}\spad{(l, options)} with \spad{maxPower == 1}.

guessPRec : List F -> GUESSRESULT
    ++ \spad{guessPRec l} tries to find a linear recurrence with
    ++ polynomial coefficients whose first values are given by l, using
    ++ the default options described in
    ++ \spadtype{GuessOptionFunctions0}. It is equivalent to
    ++ \spadfun{guessRec}\spad{(l, maxPower == 1)}.

guessRat : (List F, LGOPT) -> GUESSRESULT
    ++ \spad{guessRat(l, options)} tries to find a rational function
    ++ whose first values are given by l, using the given options. It is
    ++ equivalent to \spadfun{guessRec}\spad{(l, maxShift == 0, maxPower
    ++ == 1, allDegrees == true)}.

guessRat : List F -> GUESSRESULT
    ++ \spad{guessRat l} tries to find a rational function whose first
    ++ values are given by l, using the default options described in
    ++ \spadtype{GuessOptionFunctions0}. It is equivalent to
    ++ \spadfun{guessRec}\spad{(l, maxShift == 0, maxPower == 1,
    ++ allDegrees == true)}.

diffHP : LGOPT -> HPSPEC
    ++ \spad{diffHP options} returns a specification for Hermite-Pade
    ++ approximation with the differential operator

shiftHP : LGOPT -> HPSPEC

```

```

++ \spad{shiftHP options} returns a specification for Hermite-Pade
++ approximation with the shift operator

--      if F has RetractableTo Symbol and S has RetractableTo Symbol then

shiftHP : Symbol -> (LGOPT -> HPSPEC)
++ \spad{shiftHP options} returns a specification for
++ Hermite-Pade approximation with the  $q$ -shift operator

diffHP : Symbol -> (LGOPT -> HPSPEC)
++ \spad{diffHP options} returns a specification for Hermite-Pade
++ approximation with the  $q$ -dilation operator

guessRec : Symbol -> GUESSER
++ \spad{guessRec q} returns a guesser that finds an ordinary
++  $q$ -difference equation whose first values are given by 1, using
++ the given options.

guessPRec : Symbol -> GUESSER
++ \spad{guessPRec q} returns a guesser that tries to find
++ a linear  $q$ -recurrence with polynomial coefficients whose first
++ values are given by 1, using the given options. It is
++ equivalent to \spadfun{guessRec}\spad{(q)} with
++ \spad{maxPower == 1}.

guessRat : Symbol -> GUESSER
++ \spad{guessRat q} returns a guesser that tries to find a
++  $q$ -rational function whose first values are given by 1, using
++ the given options. It is equivalent to \spadfun{guessRec} with
++ \spad{(1, maxShift == 0, maxPower == 1, allDegrees == true)}.

guessADE : Symbol -> GUESSER
++ \spad{guessADE q} returns a guesser that tries to find an
++ algebraic differential equation for a generating function whose
++ first Taylor coefficients are given by 1, using the given
++ options.

**Exports:**

increment incrementBy

— package INCRMAPS IncrementingMaps —

```

)abbrev package INCRMAPS IncrementingMaps
++ Date Last Updated: June 4, 1991
++ Description:
++ This package provides operations to create incrementing functions.

IncrementingMaps(R) : SIG == CODE where
  R : Join(Monoid, AbelianSemiGroup)

SIG ==> with

  increment : () -> (R -> R)
    ++ increment() produces a function which adds \spad{1} to whatever
    ++ argument it is given. For example, if {f := increment()} then
    ++ \spad{f x} is \spad{x+1}.

  incrementBy : R -> (R -> R)
    ++ incrementBy(n) produces a function which adds \spad{n} to whatever
    ++ argument it is given. For example, if {f := increment(n)} then
    ++ \spad{f x} is \spad{x+n}.

CODE ==> add

  increment() == x +-> 1 + x

  incrementBy n == x +-> n + x

```

InnerMatrixLinearAlgebraFunctions is an internal package which provides standard linear algebra functions on domains in MatrixCategory.

See Also:

o)show InnerMatrixLinearAlgebraFunctions

InnerMatrixLinearAlgebraFunctions (IMATLIN)

Exports:

— package IMATLIN InnerMatrixLinearAlgebraFunctions —

```

)abbrev package IMATLIN InnerMatrixLinearAlgebraFunctions
++ Author: Clifton J. Williamson, P.Gianni
++ Date Created: 13 November 1989
++ Date Last Updated: September 1993
++ Description:
++ \spadtype{InnerMatrixLinearAlgebraFunctions} is an internal package
++ which provides standard linear algebra functions on domains in
++ \spad{MatrixCategory}

InnerMatrixLinearAlgebraFunctions(R,Row,Col,M) : SIG == CODE where
  R   : Field
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M   : MatrixCategory(R,Row,Col)

I ==> Integer

SIG ==> with

  rowEchelon : M -> M
    ++ \spad{rowEchelon(m)} returns the row echelon form of the matrix m.

  rank : M -> NonNegativeInteger
  
```

```

    ++ \spad{rank(m)} returns the rank of the matrix m.

nullity : M -> NonNegativeInteger
    ++ \spad{nullity(m)} returns the nullity of the matrix m. This is the
    ++ dimension of the null space of the matrix m.

if Col has shallowlyMutable then

    nullSpace : M -> List Col
        ++ \spad{nullSpace(m)} returns a basis for the null space of the
        ++ matrix m.

determinant : M -> R
    ++ \spad{determinant(m)} returns the determinant of the matrix m.
    ++ an error message is returned if the matrix is not square.

generalizedInverse : M -> M
    ++ \spad{generalizedInverse(m)} returns the generalized (Moore--Penrose)
    ++ inverse of the matrix m, the matrix h such that
    ++ m*h*m=h, h*m*h=h, m*h and h*m are both symmetric matrices.

inverse : M -> Union(M,"failed")
    ++ \spad{inverse(m)} returns the inverse of the matrix m.
    ++ If the matrix is not invertible, "failed" is returned.
    ++ Error: if the matrix is not square.

++       in GF(2^n)
++ Itoh88 A fast algorithm for computing multiplicative inverses
++       in GF(2^m) using normal bases
++ Description:
++ InnerNormalBasisFieldFunctions(GF) (unexposed):
++ This package has functions used by
++ every normal basis finite field extension domain.

InnerNormalBasisFieldFunctions(GF) : SIG == CODE where
  GF      : FiniteFieldCategory      -- the ground field

  PI  ==> PositiveInteger
  NNI  ==> NonNegativeInteger
  I    ==> Integer
  SI   ==> SingleInteger
  SUP  ==> SparseUnivariatePolynomial
  VGF  ==> Vector GF
  M    ==> Matrix
  V    ==> Vector
  L    ==> List
  OUT  ==> OutputForm
  TERM ==> Record(value:GF,index:SI)
  MM   ==> ModMonic(GF,SUP GF)

SIG ==> with

  setFieldInfo : (V L TERM,GF) -> Void
    ++ setFieldInfo(m,p) initializes the field arithmetic, where m is
    ++ the multiplication table and p is the respective normal element
    ++ of the ground field GF.

  random : PI -> VGF
    ++ random(n) creates a vector over the ground field with random entries.

  index : (PI,PI) -> VGF
    ++ index(n,m) is a index function for vectors of length n over
    ++ the ground field.

  pol : VGF -> SUP GF
    ++ pol(v) turns the vector \spad{[v0,...,vn]} into the polynomial
    ++ \spad{v0+v1*x+ ... + vn*x**n}.

  xn : NNI -> SUP GF

```

```

++ xn(n) returns the polynomial \spad{x**n-1}.

dAndcExp : (VGF,NNI,SI) -> VGF
++ dAndcExp(v,n,k) computes \spad{v**e} interpreting v as an element of
++ normal basis field. A divide and conquer algorithm similar to the
++ one from D.R.Stinson,
++ "Some observations on parallel Algorithms for fast exponentiation in
++ GF(2^n)", Siam J. Computation, Vol.19, No.4, pp.711-717, August 1990
++ is used. Argument k is a parameter of this algorithm.

repSq : (VGF,NNI) -> VGF
++ repSq(v,e) computes \spad{v**e} by repeated squaring,
++ interpreting v as an element of a normal basis field.

expPot : (VGF,SI,SI) -> VGF
++ expPot(v,e,d) returns the sum from \spad{i = 0} to
++ \spad{e - 1} of \spad{v**(q**i*d)}, interpreting
++ v as an element of a normal basis field and where q is
++ the size of the ground field.
++ Note that for a description of the algorithm, see
++ T.Itoh and S.Tsujii,
++ "A fast algorithm for computing multiplicative inverses in GF(2^m)
++ using normal bases",
++ Information and Computation 78, pp.171-177, 1988.

qPot : (VGF,I) -> VGF
++ qPot(v,e) computes \spad{v**(q**e)}, interpreting v as an element of
++ normal basis field, q the size of the ground field.
++ This is done by a cyclic e-shift of the vector v.

SIG ==> with

charpol : MK -> SUK
++ charpol(m) computes the characteristic polynomial of a matrix
++ m with entries in K.
++ This function returns a polynomial
++ over K, while the general one (that is in EiegenPackage) returns
++ Fraction P K

solve1 : (SUK, Par) -> List F
++ solve1(pol, eps) finds the roots of the univariate polynomial
++ polynomial pol to precision eps. If K is \spad{Fraction Integer}
++ then only the real roots are returned, if K is
++ \spad{Complex Fraction Integer} then all roots are found.

innerEigenvectors : (MK,Par,UFactor) -> List(outForm)
++ innerEigenvectors(m,eps,factor) computes explicitly
++ the eigenvalues and the correspondent eigenvectors
++ of the matrix m. The parameter eps determines the type of
++ the output, factor is the univariate factorizer to be used
++ to reduce the characteristic polynomial into irreducible factors.

InnerNumericFloatSolvePackage examples
=====
```

This is an internal package
for computing approximate solutions to systems of polynomial equations.
The parameter K specifies the coefficient field of the input polynomials
and must be either Fraction(Integer) or
Complex(Fraction Integer).

The parameter F specifies where the solutions must lie and can
be one of the following: Float, Fraction(Integer), Complex(Float), or
Complex(Fraction Integer). The last parameter specifies the type
of the precision operand and must be either Fraction(Integer) or Float.

++ Date Created: 4 April 1988
++ Date Last Updated: 9 October 1993
++ Description:
++ This package provides transformations from trigonometric functions
++ to exponentials and logarithms, and back.
++ F and FG should be the same type of function space.

InnerTrigonometricManipulations(R,F,FG) : SIG == CODE where
  R : Join(IntegralDomain, OrderedSet)
  F : Join(FunctionSpace R, RadicalCategory,
           TranscendentalFunctionCategory)
  FG : Join(FunctionSpace Complex R, RadicalCategory,
            TranscendentalFunctionCategory)

Z ==> Integer
SY ==> Symbol
OP ==> BasicOperator
GR ==> Complex R
GF ==> Complex F
KG ==> Kernel FG
PG ==> SparseMultivariatePolynomial(GR, KG)
UP ==> SparseUnivariatePolynomial PG
NTHR ==> "nthRoot":SY

SIG ==> with

GF2FG : GF -> FG
  ++ GF2FG(a + i b) returns \spad{a + i b} viewed as a function with
  ++ the \spad{i} pushed down into the coefficient domain.

FG2F : FG -> F
  ++ FG2F(a + i b) returns \spad{a + sqrt(-1) b}.

F2FG : F -> FG
  ++ F2FG(a + sqrt(-1) b) returns \spad{a + i b}.

explogs2trigs : FG -> GF
  ++ explogs2trigs(f) rewrites all the complex logs and
  ++ exponentials appearing in \spad{f} in terms of trigonometric
  ++ functions.

trigs2explogs : (FG, List KG, List SY) -> FG
  ++ trigs2explogs(f, [k1,...,kn], [x1,...,xm]) rewrites
  ++ all the trigonometric functions appearing in \spad{f} and involving
  ++ one of the \spad{xi's} in terms of complex logarithms and

```

```

++ exponentials. A kernel of the form \spad{tan(u)} is expressed
++ using \spad{exp(u)**2} if it is one of the \spad{ki's}, in terms of
++ \spad{exp(2*u)} otherwise.

```

Bug! Cannot precompute params and return a function which simply computes the last call. For example, ridHack1, below.

Functions related to the binary representation of integers. These functions directly access the bits in the big integer representation and so are much faster than using a quotient loop.

=====

IntegerCombinatoricFunctions examples

=====

IntegerCombinatoricFunctions package provides some standard functions in combinatorics.

The binomial(n, r) returns the number of subsets of r objects taken among n objects, $n!/(r! * (n-r)!)$

The binomial coefficients are the coefficients of the series expansion of a power of a binomial, that is

$$\sum_{k=0}^n \binom{n}{k} x^k = (1+x)^n$$

This leads to the famous pascal triangle. First we expose the OutputForm domain, which is normally hidden, so we can use it to format the lines.

```
)set expose add constructor OutputForm
```

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

```
pascalRow(n) == [right(binomial(n,i),4) for i in 0..n]
```

and now we format the whole line so that it looks centered:

```
displayRow(n)==output center blankSeparate pascalRow(n)
```

and we compute the triangle

```
for i in 0..7 repeat displayRow i
```

giving the pretty result:

```
Compiling function pascalRow with type NonNegativeInteger -> List
  OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void
```

```

      1
     1 1
    1 2 1
   1 3 3 1
  1 4 6 4 1
 1 5 10 10 5 1
1 6 15 20 15 6 1
1 7 21 35 35 21 7 1
```

IntegerFactorizationPackage examples

This Package contains basic methods for integer factorization. The factor operation employs trial division up to 10,000. It then tests to see if n is a perfect power before using Pollards rho method. Because Pollards method may fail, the result of factor may contain composite factors. We should also employ Lenstra's elliptic curve method.

```

PollardSmallFactor

This is Brent's optimization of Pollard's rho factoring. Brent's algorithm is about 24 percent faster than Pollard's. Pollard's algorithm has complexity $O(p^{1/2})$ where p is the smallest prime factor of the composite number N .

Pollard's idea is based on the observation that two numbers x and y are congruent modulo p with probability 0.5 after $1.177 * \sqrt{p}$ numbers have been randomly chosen. If we try to factor n and p is a factor of n , then

$$1 < \gcd(|x - y|, n) \leq n$$

since p divides both $|x - y|$ and n .

Given a function f which generates a pseudo-random sequence of numbers we allow x to walk the sequence in order and y to walk the sequence at twice the rate. At each cycle we compute $\gcd(|x - y|, n)$. If this GCD ever equals n then $x = y$ which means that we have walked "all the way around the pseudo-random cycle" and we terminate with failure.

This algorithm returns failure on all primes but also fails on some composite numbers.

Quoting Brent's back-tracking idea:

The best-known algorithm for finding GCDs is the Euclidean algorithm which takes $O(\log N)$ times as long as one multiplication mod N . Pollard showed that most of the GCD computations in Floyd's algorithm could be dispensed with. ... The idea is simple: if P_F computes $GCD(z_1, N)$, $GCD(z_2, N)$, ..., then we compute

$$q_i = \prod_{j=1}^i z_j \pmod{N}$$

and only compute $GCD(q_i, N)$ when i is a multiple of m , where $\log N \ll m \ll N^{1/4}$. Since $q_{i+1} = q_i \times z_{i+1} \pmod{N}$, the work required for each GCD computation in algorithm P_F is effectively reduced to that for a multiplication mod N in the modified algorithm. The probability of the algorithm failing because $q_i = 0$ increases, so it is best not to choose m too large. This problem can be minimized by backtracking to the state after the previous GCD computation and setting $m = 1$.

Brent incorporates back-tracking, omits the random choice of u , and makes some minor modifications. His algorithm (p192-183) reads:

```

y := x0; r := 1; q := 1;
repeat x := y;
  for i := 1 to r do y := f(y); k := 0;
  repeat ys := y;
    for i := 1 to min(m, r - k) do
      begin y := f(y); q := q * |x - y| mod N

```

```

    end;
     $G := \text{GCD}(q, N); k := k + m$ 
    until  $(k \geq r)$  or  $(G > 1); r := 2 * r$ 
until  $G > 1$ ;
if  $G = N$  then
    repeat  $ys := f(ys); G := \text{GCD}(|y - yx|, N)$ 
    until  $G > 1$ ;
    if  $G = N$  then failure else success

```

Here we use the function

$$(y * y + 5 :: I) \text{ rem } n$$

as our pseudo-random sequence with a random starting value for y.

One possible optimization to explore is to keep a hash table for the computed values of the function $y_{i+1} := f(y_i)$ since we effectively walk the sequence several times. And we walk the sequence in a loop many times. But because we are generating a very large number of numbers the array can be a simple array of fixed size that captures the last n values. So if we make a fixed array F of, say 2^q elements we can store $f(y_i)$ in $F[y_i \bmod 2^q]$.

One property that this algorithm assumes is that the function used to generate the numbers has a long, hopefully complete, period. It is not clear that the recommended function has that property.

    G := gcd(abs(x-ys),n)
G=n => "failed"
G

```

BasicSieve

We create a list of prime numbers up to the limit given. The prior code used a circular list but tests of that list show that on average more than 50% the required prime numbers. Overall this is a small percentage of the time needed to factor.

This loop uses three pieces of information

1. n which is the number we are testing
2. d which is the current prime to test
3. lim which is the upper limit of the primes to test

We loop d over the list of primes. If the remaining number n is smaller than the square of d then n must be prime and if it is not one, we add it to the list of primes. If the remaining number is larger than the square of d we remove all factors of d, reducing n each time. Then we add a record of the new factor and its multiplicity, m. We continue the loop until we run out of primes.

Annoyingly enough, primes does not return an ordered list so we fix this.

The sieve works up to a given limit, reducing out the factors that it finds. If it can find all of the factors than it returns a factored result where the first element is the unit 1. If there is still a part of the number unfactored it returns the number and a list of the factors found and their multiplicity.

Basically we just loop thru the prime factors checking to see if they are a component of the number, n. If so, we remove the factor from the number n (possibly m times) and continue thru the list of primes.

— **package INTFACT IntegerFactorizationPackage** —

```

BasicSieve(n, lim) ==
  p:=primes(1::I,lim::I)$IntegerPrimesPackage(I)
  l:List(I) := append([first p],reverse rest p)

=====
IntegerLinearDependence examples
=====

```

This packages tests for linear dependence over the integers.

The elements $v_1, \dots, v_N$ of a module M over a ring R are said to be linearly dependent over R if there exist $c_1, \dots, c_N$ in R , not all 0, such that $c_1 v_1 + \dots + c_N v_N = 0$. If such c_i 's exist, they form what is called a linear dependence relation over R for the v_i 's.

The package `IntegerLinearDependence` provides functions for testing whether some elements of a module over the integers are linearly dependent over the integers, and to find the linear dependence relations, if any.

Consider the domain of two by two square matrices with integer entries.

```
M := SQMATRIX(2,INT)
SquareMatrix(2,Integer)
Type: Domain
```

Now create three such matrices.

```
m1: M := squareMatrix matrix [ [1, 2], [0, -1] ]
+1 2 +
|   |
+0 -1+
Type: SquareMatrix(2,Integer)
```

```
m2: M := squareMatrix matrix [ [2, 3], [1, -2] ]
+2 3 +
|   |
+1 -2+
Type: SquareMatrix(2,Integer)
```

```
m3: M := squareMatrix matrix [ [3, 4], [2, -3] ]
+3 4 +
|   |
+2 -3+
Type: SquareMatrix(2,Integer)
```

This tells you whether m_1 , m_2 and m_3 are linearly dependent over the integers.

```
linearlyDependentOverZ? vector [m1, m2, m3]
true
Type: Boolean
```

Since they are linearly dependent, you can ask for the dependence relation.

```
c := linearDependenceOverZ vector [m1, m2, m3]
[1, -2, 1]
Type: Union(Vector Integer,...)
```

This means that the following linear combination should be 0.

```
c.1 * m1 + c.2 * m2 + c.3 * m3
+0  0+
|    |
+0  0+

Type: SquareMatrix(2,Integer)
```

When a given set of elements are linearly dependent over R , this also means that at least one of them can be rewritten as a linear combination of the others with coefficients in the quotient field of R .

To express a given element in terms of other elements, use the operation `solveLinearlyOverQ`.

```
solveLinearlyOverQ(vector [m1, m3], m2)
  1 1
  [-,-]
  2 2

Type: Union(Vector Fraction Integer,...)
```

=====
IntegerNumberTheoryFunctions examples
=====

```

This package provides various number theoretic functions on the integers.

The IntegerNumberTheoryFunctions package contains a variety of operations of interest to number theorists. Many of these operations deal with divisibility properties of integers. (Recall that an integer a divides an integer b if there is an integer c such that $b = a * c$.)

The operation `divisors` returns a list of the divisors of an integer.

```

div144 := divisors(144)
      [1,2,3,4,6,8,9,12,16,18,24,36,48,72,144]
                        Type: List Integer

```

You can now compute the number of divisors of 144 and the sum of the divisors of 144 by counting and summing the elements of the list we just created.

```

#(div144)
      15
                        Type: PositiveInteger

reduce(+,div144)
      403
                        Type: PositiveInteger

```

Of course, you can compute the number of divisors of an integer n , usually denoted $d(n)$, and the sum of the divisors of an integer n , usually denoted $\sigma(n)$, without ever listing the divisors of n .

In Axiom, you can simply call the operations `numberOfDivisors` and `sumOfDivisors`.

```
numberOfDivisors(144)
15
Type: PositiveInteger

sumOfDivisors(144)
403
Type: PositiveInteger
```

The key is that $d(n)$ and $\sigma(n)$ are "multiplicative functions." This means that when n and m are relatively prime, that is, when n and m have no prime factor in common, then $d(nm) = d(n) d(m)$ and $\sigma(nm) = \sigma(n) \sigma(m)$. Note that these functions are trivial to compute when n is a prime power and are computed for general n from the prime factorization of n . Other examples of multiplicative functions are $\sigma_k(n)$, the sum of the k -th powers of the divisors of n and $\varphi(n)$, the number of integers between 1 and n which are prime to n . The corresponding Axiom operations are called `sumOfKthPowerDivisors` and `eulerPhi`.

An interesting function is $\mu(n)$, the Moebius μ function, defined as follows: $\mu(1) = 1$, $\mu(n) = 0$, when n is divisible by a square, and $\mu = (-1)^k$, when n is the product of k distinct primes. The corresponding Axiom operation is `moebiusMu`. This function occurs in the following theorem:

Theorem: (Moebius Inversion Formula):

Let $f(n)$ be a function on the positive integers and let $F(n)$ be defined by

$$F(n) = \sum_{d|n} f(d)$$
the sum of $f(n)$ over $d | n$ where the sum is taken over the positive divisors of n . Then the values of $f(n)$ can be recovered from the values of $F(n)$: $f(n) = \sum_{d|n} \mu(d) F(n/d)$ where again the sum is taken over the positive divisors of n .

When $f(n) = 1$, then $F(n) = d(n)$. Thus, if you sum $\mu(d) \cdot d(n/d)$ over the positive divisors d of n , you should always get 1.

```
f1(n)==reduce(+,[moebiusMu(d)*numberOfDivisors(quo(n,d))_
for d in divisors(n)])
Type: Void

f1(200)
1
Type: PositiveInteger
```

```
f1(846)
```

```
1
```

```
Type: PositiveInteger
```

Similarly, when $f(n) = n$, then $F(n) = \sigma(n)$. Thus, if you sum $\mu(d) \cdot \sigma(n/d)$ over the positive divisors d of n , you should always get n .

```
f2(n) == reduce(+,[moebiusMu(d) * sumOfDivisors(quo(n,d))_
  for d in divisors(n)])
```

```
Type: Void
```

```
f2(200)
```

```
200
```

```
Type: PositiveInteger
```

```
f2(846)
```

```
846
```

```
Type: PositiveInteger
```

The Fibonacci numbers are defined by

$F(1) = F(2) = 1$ and

$F(n) = F(n-1) + F(n-2)$ for $n = 3, 4, \dots$

The operation `fibonacci` computes the n -th Fibonacci number.

```
fibonacci(25)
```

```
75025
```

```
Type: PositiveInteger
```

```
[fibonacci(n) for n in 1..15]
```

```
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
```

```
Type: List Integer
```

Fibonacci numbers can also be expressed as sums of binomial coefficients.

```
fib(n) == reduce(+,[binomial(n-1-k,k) for k in 0..quo(n-1,2)])
```

```
Type: Void
```

```
fib(25)
```

```
75025
```

```
Type: PositiveInteger
```

```
[fib(n) for n in 1..15]
```

```
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
```

```
Type: List Integer
```

Quadratic symbols can be computed with the operations `legendre` and `jacobi`. The Legendre symbol a/p is defined for integers a and p with p an odd prime number. By definition,

$(a/p) = +1$, when a is a square (mod p),
 $(a/p) = -1$, when a is not a square (mod p), and
 $(a/p) = 0$, when a is divisible by p .

You compute (a/p) via the command `legendre(a,p)`.

```

legendre(3,5)
- 1
                                Type: Integer

```

```

legendre(23,691)
- 1
                                Type: Integer

```

The Jacobi symbol (a/n) is the usual extension of the Legendre symbol, where n is an arbitrary integer. The most important property of the Jacobi symbol is the following: if K is a quadratic field with discriminant d and quadratic character χ , then $\chi(n) = (d/n)$. Thus, you can use the Jacobi symbol to compute, say, the class numbers of imaginary quadratic fields from a standard class number formula.

This function computes the class number of the imaginary quadratic field with discriminant d .

```

h(d) == quo(reduce(+,[jacobi(d,k) for k in 1..quo(-d, 2)]),2-jacobi(d,2))
                                Type: Void

```

```

=====
The inverse function
=====

```

The inverse function is derived from the Extended Euclidean Algorithm. If we divide one integer by another nonzero integer we get an integer quotient plus a remainder which is, in general, a rational number. For instance,

$$13/5 = 2 + 3/5$$

where 2 is the quotient and 3/5 is the remainder.

If we multiply thru by the denominator of the remainder we get an answer in integer terms which no longer involves division:

$$13 = 2(5) + 3$$

This gives a method of dividing integers. Specifically, if a and b are positive integers, there exist unique non-negative integers q and r so that

$$a = qb + r, \text{ where } 0 \leq r < b$$

q is called the quotient and r the remainder.

The greatest common divisor of integers a and b , denoted by $\gcd(a,b)$, is the largest integer that divides (without remainder) both a and b . So, for example:

$$\begin{aligned}\gcd(15, 5) &= 5, \\ \gcd(7, 9) &= 1, \\ \gcd(12, 9) &= 3, \\ \gcd(81, 57) &= 3.\end{aligned}$$

The gcd of two integers can be found by repeated application of the division algorithm, this is known as the Euclidean Algorithm. You repeatedly divide the divisor by the remainder until the remainder is 0. The gcd is the last non-zero remainder in this algorithm. The following example shows the algorithm.

Finding the gcd of 81 and 57 by the Euclidean Algorithm:

$$\begin{aligned}81 &= 1(57) + 24 \\ 57 &= 2(24) + 9 \\ 24 &= 2(9) + 6 \\ 9 &= 1(6) + 3 \\ 6 &= 2(3) + 0\end{aligned}$$

So the greatest common divisor, the $\gcd(81,51)=3$.

If the $\gcd(a, b) = r$ then there exist integers s and t so that

$$s(a) + t(b) = r$$

By back substitution in the steps in the Euclidean Algorithm, it is possible to find these integers s and t . We shall do this with the above example:

Starting with the next to last line, we have:

$$3 = 9 - 1(6)$$

From the line before that, we see that $6 = 24 - 2(9)$, so:

$$3 = 9 - 1(24 - 2(9)) = 3(9) - 1(24)$$

From the line before that, we have $9 = 57 - 2(24)$, so:

$$3 = 3(57 - 2(24)) - 1(24) = 3(57) - 7(24)$$

And, from the line before that $24 = 81 - 1(57)$, giving us:

$$3 = 3(57) - 7(81 - 1(57)) = 10(57) - 7(81)$$

So we have found $s = -7$ and $t = 10$.

The Extended Euclidean Algorithm computes the $\text{GCD}(a,b)$ and the values for s and t .

Suppose we were doing arithmetics modulo 26 and we needed to find the inverse of a number mod 26. This turned out to be a difficult task (and not always possible). We observed that a number x had an inverse mod 26 (a number y so that $xy = 1 \text{ mod } 26$) if and only if $\text{gcd}(x, 26) = 1$. In the general case the inverse of x exists if and only if $\text{gcd}(x, n) = 1$ and if it exists then there exist integers s and t so that

$$sx + tn = 1$$

But this says that $sx = 1 + (-t)n$, or in other words,

$$sx \equiv 1 \text{ mod } n$$

So, s (reduced mod n if need be) is the inverse of x mod n . The extended Euclidean algorithm calculates s efficiently.

```
=====
Finding the inverse mod n
=====
```

We will number the steps of the Euclidean algorithm starting with step 0. The quotient obtained at step i will be denoted by q_i and an auxillary number, s_i . For the first two steps, the value of this number is given:

$$\begin{aligned} s(0) &= 0 \text{ and} \\ s(1) &= 1. \end{aligned}$$

For the remainder of the steps, we recursively calculate

$$s(i) = s(i-2) - s(i-1) q(i-2) \text{ mod } n$$

The algorithm starts by "dividing" n by x . If the last non-zero remainder occurs at step k , then if this remainder is 1, x has an inverse and it is $s(k+2)$. If the remainder is not 1, then x does not have an inverse.

For example, find the inverse of 15 mod 26.

$$\text{Step 0: } 26 = 1(15) + 11 \quad s(0) = 0$$

Step 1: $15 = 1(11) + 4$ $s(1) = 1$
 Step 2: $11 = 2(4) + 3$ $s(2) = 0 - 1(1) \bmod 26 = 25$
 Step 3: $4 = 1(3) + 1$ $s(3) = 1 - 25(1) \bmod 26 = -24 \bmod 26 = 2$
 Step 4: $3 = 3(1) + 0$ $s(4) = 25 - 2(2) \bmod 26 = 21$
 $s(5) = 2 - 21(1) \bmod 26 = -19 \bmod 26 = 7$

Notice that $15(7) = 105 = 1 + 4(26) \equiv 1 \pmod{26}$.

Using the half extended Euclidean algorithm we compute $1/a \bmod b$.

```
inverse:(INT,INT)->INT
```

Type: Void

```
=====
The Chinese Remainder Algorithm
=====
```

The Chinese Remainder Theorem says that given n moduli m_i for $(1 \leq i \leq n)$ of pairwise coprime integers and a set of congruential equations $x \equiv c_i \pmod{m_i}$ $(1 \leq i \leq n)$ for an arbitrary integer x , there is a unique solution c for x modulo the product $M = \prod_{i=1}^n m_i$, say $x \equiv c \pmod{M}$.

If the upper bound B of the absolute value of x is known, that is, if

$|x| \leq B$ then the number of moduli can be chosen such that $B < M/2$. If c is the absolutely least residue modulo M then c and x coincide so x is uniquely determined.

Let $m_1, m_2, \dots, m_r$ be positive integers that are pairwise relatively prime. Let $x_1, x_2, \dots, x_r$ be integers with $0 \leq x_i < m_i$. Then, there is exactly one x in the interval $0 \leq x < m_1 \dots m_2 \dots m_r$ that satisfies the remainder equations

$$\text{irem}(x, m_i) = x_i, \quad i=1, 2, \dots, r$$

where irem is the positive integer remainder function.

For example, let $x_1 = 4$, $m_1 = 5$, $x_2 = 2$, $m_2 = 3$. We know that

$$\text{irem}(x, m_1) = x_1$$

$$\text{irem}(x, m_2) = x_2$$

where $0 \leq x_1 < m_1$ and $0 \leq x_2 < m_2$.

By the extended Euclidean Algorithm there are integers c and d such that

$$c m_1 + d m_2 = 1$$

In this case we are looking for an integer such that

$$\text{irem}(x, 5) = 4,$$

$$\text{irem}(x, 3) = 2$$

The algorithm we use is to first compute the positive integer remainder of x_1 and m_1 to get a new x_1 :

$$x_1 = \text{positiveRemainder}(x_1, m_1)$$

$$4 = \text{positiveRemainder}(4, 5)$$

Next compute the positive integer remainder of x_2 and m_2 to get a new x_2 :

$$x_2 = \text{positiveRemainder}(x_2, m_2)$$

$$2 = \text{positiveRemainder}(2, 3)$$

Then we compute $x_1 + m_1 \dots \text{positiveRemainder}((x_2 - x_1) * \text{inverse}(m_1, m_2)), m_2)$
or

$$4 + 5 * \text{positiveRemainder}(((2 - 4) * \text{inverse}(5, 3))), 3)$$

or

$$4 + 5 * \text{positiveRemainder}(-2 * 2), 3)$$

or

$$4 + 5 * 2$$

or

$$14$$

This function has a restricted signature which only allows for computing the chinese remainder of two numbers and two moduli.

$$x_1 := 4$$

$$4$$

)abbrev package INTHEORY IntegerNumberTheoryFunctions
++ Author: Michael Monagan, Martin Brock, Robert Sutor, Timothy Daly
++ Date Created: June 1987
++ References: Knuth, The Art of Computer Programming Vol.2
++ Description:
++ This package provides various number theoretic functions on the integers.

```

IntegerNumberTheoryFunctions() : SIG == CODE where

```

I ==> Integer
RN ==> Fraction I
SUP ==> SparseUnivariatePolynomial
NNI ==> NonNegativeInteger

SIG ==> with

bernoulli : I -> RN
++ \spad{bernoulli(n)} returns the nth Bernoulli number.
++ this is \spad{B(n,0)}, where \spad{B(n,x)} is the \spad{n}th Bernoulli
++ polynomial.

chineseRemainder : (I,I,I,I) -> I
++ \spad{chineseRemainder(x1,m1,x2,m2)} returns w, where w is such that
++ \spad{w = x1 mod m1} and \spad{w = x2 mod m2}. Note that \spad{m1} and
++ \spad{m2} must be relatively prime.

divisors : I -> List I
++ \spad{divisors(n)} returns a list of the divisors of n.

euler : I -> I
++ \spad{euler(n)} returns the \spad{n}th Euler number. This is
++ \spad{2^n E(n,1/2)}, where \spad{E(n,x)} is the nth Euler polynomial.

eulerPhi : I -> I
++ \spad{eulerPhi(n)} returns the number of integers between 1 and n
++ (including 1) which are relatively prime to n. This is the Euler phi
++ function \spad{\phi(n)} is also called the totient function.

fibonacci : I -> I
++ \spad{fibonacci(n)} returns the nth Fibonacci number. the Fibonacci
++ numbers \spad{F[n]} are defined by \spad{F[0] = F[1] = 1} and
++ \spad{F[n] = F[n-1] + F[n-2]}.
++ The algorithm has running time \spad{O(log(n)^3)}.
++ Reference: Knuth, The Art of Computer Programming
++ Vol 2, Semi-Numerical Algorithms.

harmonic : I -> RN
++ \spad{harmonic(n)} returns the nth harmonic number. This is
++ \spad{H[n] = sum(1/k,k=1..n)}.

jacobi : (I,I) -> I
++ \spad{jacobi(a,b)} returns the Jacobi symbol \spad{J(a/b)}.
++ When b is odd, \spad{J(a/b) = product(L(a/p) for p in factor b )}.
++ Note that by convention, 0 is returned if \spad{gcd(a,b) ^= 1}.
++ Iterative \spad{O(log(b)^2)} version coded by Michael Monagan June 1987.

```

```

legendre : (I,I) -> I
++ \spad{legendre(a,p)} returns the Legendre symbol \spad{L(a/p)}.
++ \spad{L(a/p)} =  $(-1)^{((p-1)/2)} \bmod p$  (p prime), which is 0 if \spad{a}
++ is 0, 1 if \spad{a} is a quadratic residue \spad{mod p} and -1 otherwise.
++ Note that because the primality test is expensive,
++ if it is known that p is prime then use \spad{jacobi(a,p)}.

moebiusMu : I -> I
++ \spad{moebiusMu(n)} returns the Moebius function \spad{mu(n)}.
++ \spad{mu(n)} is either -1,0 or 1 as follows:
++ \spad{mu(n) = 0} if n is divisible by a square > 1,
++ \spad{mu(n) =  $(-1)^k$ } if n is square-free and has k distinct
++ prime divisors.

numberOfDivisors: I -> I
++ \spad{numberOfDivisors(n)} returns the number of integers between 1 and n
++ (inclusive) which divide n. The number of divisors of n is often
++ denoted by \spad{tau(n)}.

sumOfDivisors : I -> I
++ \spad{sumOfDivisors(n)} returns the sum of the integers between 1 and n
++ (inclusive) which divide n. The sum of the divisors of n is often
++ denoted by \spad{sigma(n)}.

sumOfKthPowerDivisors: (I,NNI) -> I
++ \spad{sumOfKthPowerDivisors(n,k)} returns the sum of the \spad{k}th
++ powers of the integers between 1 and n (inclusive) which divide n.
++ the sum of the \spad{k}th powers of the divisors of n is often denoted
++ by \spad{sigma_k(n)}.

Rabin-Miller testing

In Arnault[Arna95] we find

The primality test of Axiom release 1.1 is a Rabin-Miller test where the set of bases used depends on the size of the number tested. For numbers less than 341550071728321 the Axiom test is always correct due to the results of Jaeschke (1993). For numbers greater than this bound, the Axiom test uses the first ten odd prime bases 3, 5, 7, 11, 13, 17, 19, 23, 29, and 31. Release 1.1 benefits from several improvements, outlined below and added by Davenport (1992), which catch the numbers produced in Jaeschke (1993) and Arnault (1995).

When $n = 2^k q$ is checked for strong pseudoprimality, one first computes b^q modulo n and then use repeated squaring to see if there exists an i such that $b^{2^i q} \equiv -1$ modulo n . Whenever we find such an $i > 0$, we get a square root of -1 modulo n , namely $b^{2^{i-1} q}$. One idea of Davenport is to collect and count the distinct square roots of -1 we get in this process. If more than two square roots are found, then n is surely composite, even if it is a strong pseudoprime to all used bases.

The Axiom test searches also for numbers of specific forms, as the numbers produced in Arnault (1995) which are of the form $n = (u + 1)(2u + 1)$. Indeed these numbers satisfy $8n + 1 = (4u + 3)^2$ and they are easily spotted by this release of Axiom, which checks if $8n + 1$ is a perfect square.

The Axiom test reserves a special treatment to numbers n which satisfy

$$b^{(n-1)/2} \equiv 1 \text{ modulo } n$$

for the 10 bases above. These numbers are considered as suspicious and are submitted to additional strong pseudoprimality tests with other bases until one

base b is found such that $b^{(n-1)/2} \equiv -1$ modulo n or some strong pseudoprimality test fails. Fortunately for the success of the method described here, the numbers which satisfy

$$b^{(n-1)/2} \equiv 1 \text{ modulo } n$$

for the first 10 odd prime bases are not considered as suspicious.

In spite of these improvements, we are able to find composite numbers which pass the Axiom 1.1 test. For example, let $h = 3$, $k_2 = 37$, and $k_3 = 43$. The right hand of

$$p_1 \bmod 4b \in \cap_{i=1}^h k_i^{-1}(S_b + k_i - 1)$$

is not empty, for each of the ten bases used by Axiom, in which we choose values from

- b=3: $p_1 \equiv 7 \pmod{12}$
- b=5: $p_1 \equiv 7 \pmod{20}$
- b=7: $p_1 \equiv 15 \pmod{28}$
- b=11: $p_1 \equiv 23 \pmod{44}$
- b=13: $p_1 \equiv 11 \pmod{52}$
- b=17: $p_1 \equiv 11 \pmod{68}$
- b=19: $p_1 \equiv 39 \pmod{76}$
- b=23: $p_1 \equiv 39 \pmod{92}$
- b=29: $p_1 \equiv 43 \pmod{116}$
- b=31: $p_1 \equiv 63 \pmod{124}$

Also, the coefficients m_2 and m_3 will be integers as soon as

$$p_1 \equiv 9 \text{ modulo } 37 \quad \text{and} \quad p_1 \equiv 31 \text{ modulo } 41$$

These two congruences and those of the table above can be together written

$$p_1 \equiv 356794315112467 \text{ modulo } 608500527054420$$

Take $p_1 = 356794315112467$, we find the following number, which passes the Axiom test:

$$n = 16293065699588634810831933763781141498750450660078823067$$

The same method has been used with a large set of bases in order to construct the 397-digit Carmichael number

$$n = p_1[313(p_1 - 1) + 1][353(p_1 - 1) + 1]$$

where

$$p_1 = 29674495668685510550154174642905332730771991799853043350995075531$$

$$276838753171770199594238596428121188033664754218345562493168782883$$

which is a strong pseudoprime to all prime bases up to 300.

See Davenport[[Dave92](#)], Arnault[[Arna95](#)], Jaeschke[[Jaes93](#)]

— package **PRIMES IntegerPrimesPackage** —

```

)abbrev package PRIMES IntegerPrimesPackage
++ Author: Michael Monagan, James Davenport
++ Date Created: August 1987
++ Date Last Updated: 31 May 1993
++ References:
++ Dave92 Primality Testing Revisited
++ Arna95 Constructing Carmichael numbers which are strong pseudoprimes to
++ several bases
++ Jaes93 On Strong Pseudoprimes to Several Bases
++ Description:
++ The \spadtype{IntegerPrimesPackage} implements a modification of
++ Rabin's probabilistic
++ primality test and the utility functions \spadfun{nextPrime},
++ \spadfun{prevPrime} and \spadfun{primes}.

IntegerPrimesPackage(I) : SIG == CODE where
  I : IntegerNumberSystem

SIG ==> with

prime? : I -> Boolean
++ \spad{prime?(n)} returns true if n is prime and false if not.
++ The algorithm used is Rabin's probabilistic primality test
++ (reference: Knuth Volume 2 Semi Numerical Algorithms).
++ If \spad{prime? n} returns false, n is proven composite.
++ If \spad{prime? n} returns true, prime? may be in error
++ however, the probability of error is very low.
++ and is zero below 25*10**9 (due to a result of Pomerance et al),
++ below 10**12 and 10**13 due to results of Pinch,
++ and below 341550071728321 due to a result of Jaeschke.
++ Specifically, this implementation does at least 10 pseudo prime
++ tests and so the probability of error is \spad{< 4**(-10)}.
++ The running time of this method is cubic in the length
++ of the input n, that is \spad{0( (log n)**3 )}, for n<10**20.
++ beyond that, the algorithm is quartic, \spad{0( (log n)**4 )}.
++ Two improvements due to Davenport have been incorporated
++ which catches some trivial strong pseudo-primes, such as
++ [Jaeschke, 1991] 1377161253229053 * 413148375987157, which
++ the original algorithm regards as prime

nextPrime : I -> I
++ \spad{nextPrime(n)} returns the smallest prime strictly larger than n

prevPrime : I -> I
++ \spad{prevPrime(n)} returns the largest prime strictly smaller than n

primes : (I,I) -> List I

```

```

++ \spad{primes(a,b)} returns a list of all primes p with
++ \spad{a <= p <= b}

```

```
CODE ==> add
```

smallPrimes

This is a table of all of the primes in [2..10000]. It is used by the prime? function to check for primality. It is used by the primes function to generate arrays of primes in a given range. Changing the range included in this table implies changing the value of the nextSmallPrime variable. There is a constant in the function squareFree from IntegerFactorizationPackage that is the square of the upper bound of the table range, in this case 10000000.

matrixGcd moduleSum

— package IBAT00L IntegralBasisTools —

)abbrev package IBAT00L IntegralBasisTools
++ Author: Victor Miller, Barry Trager, Clifton Williamson
++ Date Created: 11 April 1990
++ Date Last Updated: 20 September 1994

```

++ Description:
++ This package contains functions used in the packages
++ FunctionFieldIntegralBasis and NumberFieldIntegralBasis.

IntegralBasisTools(R,UP,F) : SIG == CODE where
  R : EuclideanDomain with
      squareFree: $ -> Factored $
      ++ squareFree(x) returns a square-free factorisation of x
  UP : UnivariatePolynomialCategory R
  F : FramedAlgebra(R,UP)

Mat ==> Matrix R
NNI ==> NonNegativeInteger
Ans ==> Record(basis: Mat, basisDen: R, basisInv:Mat)

SIG ==> with

diagonalProduct : Mat -> R
  ++ diagonalProduct(m) returns the product of the elements on the
  ++ diagonal of the matrix m

matrixGcd : (Mat,R,NNI) -> R
  ++ matrixGcd(mat,sing,n) is \spad{gcd(sing,g)} where \spad{g} is the
  ++ gcd of the entries of the \spad{n}-by-\spad{n} upper-triangular
  ++ matrix \spad{mat}.

divideIfCan! : (Matrix R,Matrix R,R,Integer) -> R
  ++ divideIfCan!(matrix,matrixOut,prime,n) attempts to divide the
  ++ entries of \spad{matrix} by \spad{prime} and store the result in
  ++ \spad{matrixOut}. If it is successful, 1 is returned and if not,
  ++ \spad{prime} is returned. Here both \spad{matrix} and
  ++ \spad{matrixOut} are \spad{n}-by-\spad{n} upper triangular matrices.

leastPower : (NNI,NNI) -> NNI
  ++ leastPower(p,n) returns e, where e is the smallest integer
  ++ such that \spad{p} ** e >= n}

idealiser : (Mat,Mat) -> Mat
  ++ idealiser(m1,m2) computes the order of an ideal defined by m1 and m2

idealiser : (Mat,Mat,R) -> Mat
  ++ idealiser(m1,m2,d) computes the order of an ideal defined by m1 and m2
  ++ where d is the known part of the denominator

idealiserMatrix : (Mat, Mat) -> Mat
  ++ idealiserMatrix(m1, m2) returns the matrix representing the linear
  ++ conditions on the Ring associated with an ideal defined by m1 and m2.

moduleSum : (Ans,Ans) -> Ans
  ++ moduleSum(m1,m2) returns the sum of two modules in the framed

```

```

++ algebra \spad{F}. Each module \spad{mi} is represented as follows:
++ F is a framed algebra with R-module basis \spad{w1,w2,...,wn} and
++ \spad{mi} is a record \spad{[basis,basisDen,basisInv]}. If
++ \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
++ a basis \spad{v1,...,vn} for \spad{mi} is given by
++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, the
++ \spad{i}th row of 'basis' contains the coordinates of the
++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
++ \spad{wi = sum(bij * vj, j = 1..n)}.

IntegrationTools (INTTOOLS)**Exports:**

kmax intPatternMatch ksec mkPrim removeConstantTerm
 union vark varselect

— package INTTOOLS IntegrationTools —

```

)abbrev package INTTOOLS IntegrationTools
++ Author: Manuel Bronstein
++ Date Created: 25 April 1990
++ Date Last Updated: 9 June 1993
++ Description:
++ Tools for the integrator

IntegrationTools(R,F) : SIG == CODE where
  R : OrderedSet
  F : FunctionSpace R

K  ==> Kernel F
SE ==> Symbol
P  ==> SparseMultivariatePolynomial(R, K)
UP ==> SparseUnivariatePolynomial F
IR ==> IntegrationResult F
ANS ==> Record(special:F, integrand:F)
U  ==> Union(ANS, "failed")
ALGOP ==> "%alg"

SIG ==> with

  varselect : (List K, SE) -> List K
    ++ varselect([k1,...,kn], x) returns the ki which involve x.

  kmax : List K -> K
    ++ kmax([k1,...,kn]) returns the top-level ki for integration.

  ksec : (K, List K, SE) -> K
  
```

```

++ ksec(k, [k1,...,kn], x) returns the second top-level ki
++ after k involving x.

union : (List K, List K) -> List K
++ union(l1, l2) returns set-theoretic union of l1 and l2.

vark : (List F, SE) -> List K
++ vark([f1,...,fn],x) returns the set-theoretic union of
++ \spad{(varselect(f1,x),...,varselect(fn,x))}.

if R has IntegralDomain then

removeConstantTerm : (F, SE) -> F
++ removeConstantTerm(f, x) returns f minus any additive constant
++ with respect to x.

if R has GcdDomain and F has ElementaryFunctionCategory then

mkPrim : (F, SE) -> F
++ mkPrim(f, x) makes the logs in f which are linear in x
++ primitive with respect to x.

if R has ConvertibleTo Pattern Integer and R has PatternMatchable Integer
and F has LiouvillianFunctionCategory and F has RetractableTo SE then

intPatternMatch : (F, SE, (F, SE) -> IR, (F, SE) -> U) -> IR
++ intPatternMatch(f, x, int, pmint) tries to integrate \spad{f}
++ first by using the integration function \spad{int}, and then
++ by using the pattern match integration function \spad{pmint}
++ on any remaining unintegrable part.

=====
IrrRepSymNatPackage examples
=====

```

IrrRepSymNatPackage contains functions for computing the ordinary irreducible representations of symmetric groups on n letters $\{1, 2, \dots, n\}$ in Young's natural form and their dimensions.

These representations can be labelled by number partitions of n , a weakly decreasing sequence of integers summing up to n , for example, $[3, 3, 3, 1]$ labels an irreducible representation for n equals 10.

Note that whenever a `\spadtype{List Integer}` appears in a signature,

a partition required.

dimensionOfIrreducibleRepresentation : L I -> NNI
++ dimensionOfIrreducibleRepresentation(lambda) is the dimension
++ of the ordinary irreducible representation of the symmetric group
++ corresponding to lambda.
++ Note that the Robinson-Thrall hook formula is implemented.

irreducibleRepresentation : (L I, PERM I) -> M I
++ irreducibleRepresentation(lambda,pi) is the irreducible representation
++ corresponding to partition lambda in Young's natural form of the
++ permutation pi in the symmetric group, whose elements permute
++ {1,2,...,n}.

irreducibleRepresentation : L I -> L M I
++ irreducibleRepresentation(lambda) is the list of the two
++ irreducible representations corresponding to the partition lambda
++ in Young's natural form for the following two generators
++ of the symmetric group, whose elements permute
++ {1,2,...,n}, namely (1 2) (2-cycle) and
++ (1 2 ... n) (n-cycle).

irreducibleRepresentation : (L I, L PERM I) -> L M I
++ irreducibleRepresentation(lambda,listOfPerm) is the list of the
++ irreducible representations corresponding to lambda
++ in Young's natural form for the list of permutations
++ given by listOfPerm.

=====

LazardSetSolvingPackage examples

=====

A package for solving polynomial systems by means of Lazard triangular sets. This package provides two operations. One for solving in the sense of the regular zeros, and the other for solving in the sense of the Zariski closure. Both produce square-free regular sets. Moreover, the decompositions do not contain any redundant component. However, only zero-dimensional regular sets are normalized, since normalization may be time consuming in positive dimension. The decomposition process is that of

M. MORENO MAZA "A new algorithm for computing triangular decomposition of algebraic varieties" NAG Tech. Rep. 4/98.

The LazardSetSolvingPackage package constructor solves polynomial systems by means of Lazard triangular sets. However one condition is relaxed: Regular triangular sets whose saturated ideals have positive dimension are not necessarily normalized.

The decompositions are computed in two steps. First the algorithm of Moreno Maza (implemented in the RegularTriangularSet domain constructor) is called. Then the resulting decompositions are converted into lists of square-free regular triangular sets and the redundant components are removed. Moreover, zero-dimensional regular triangular sets are normalized.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The LazardSetSolvingPackage constructor takes six arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category GcdDomain. The second one, E, is the exponent

monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. the third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The fourth one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The fifth one is a domain of the category RegularTriangularSetCategory(R,E,V,P) and the last one is a domain of the category SquareFreeRegularTriangularSetCategory(R,E,V,P). The abbreviation for LazardSetSolvingPackage is LAZM3PK.

For the purpose of solving zero-dimensional algebraic systems, see also LexTriangularPackage and ZeroDimensionalSolvePackage. These packages are easier to call than LAZM3PK. Moreover, the ZeroDimensionalSolvePackage package provides operations to compute either the complex roots or the real roots.

We illustrate now the use of the LazardSetSolvingPackage package constructor with two examples (Butcher and Vermeer).

Define the coefficient ring.

```
R := Integer
  Integer
```

Define the list of variables,

```
ls : List Symbol := [b1,x,y,z,t,v,u,w]
  [b1,x,y,z,t,v,u,w]
```

and make it an ordered set:

```
V := OVAR(ls)
  OrderedVariableList [b1,x,y,z,t,v,u,w]
```

then define the exponent monoid.

```
E := IndexedExponents V
```

Define the polynomial ring.

```
P := NSMP(R, V)
```

Let the variables be polynomial.

```
b1: P := 'b1
```

```
x: P := 'x
```

```
y: P := 'y
```

```
z: P := 'z
```

```
t: P := 't
```

```
u: P := 'u
```

```
v: P := 'v
```

```
w: P := 'w
```

Now call the `{\tt RegularTriangularSet}` domain constructor.

```
T := REGSET(R,E,V,P)
```

Define a polynomial system (the Butcher example).

```
p0 := b1 + y + z - t - w
```

```
p1 := 2*z*u + 2*y*v + 2*t*w - 2*w**2 - w - 1
```

```
p2 := 3*z*u**2 + 3*y*v**2 - 3*t*w**2 + 3*w**3 + 3*w**2 - t + 4*w
```

```
p3 := 6*x*z*v - 6*t*w**2 + 6*w**3 - 3*t*w + 6*w**2 - t + 4*w
```

```
p4 := 4*z*u**3 + 4*y*v**3 + 4*t*w**3 - 4*w**4 - 6*w**3 + 4*t*w - 10*w**2 - w - 1
```

```
p5 := 8*x*z*u*v + 8*t*w**3 - 8*w**4 + 4*t*w**2 - 12*w**3 + 4*t*w - 14*w**2 - 3*w - 1
```

```
p6 := 12*x*z*v**2 + 12*t*w**3 - 12*w**4 + 12*t*w**2 - 18*w**3 + 8*t*w - 14*w**2 - w - 1
```

```
p7 := -24*t*w**3 + 24*w**4 - 24*t*w**2 + 36*w**3 - 8*t*w + 26*w**2 + 7*w + 1
```

```
lp := [p0, p1, p2, p3, p4, p5, p6, p7]
```

```
[b1 + y + z - t - w, 2v y + 2u z + 2w t - 2w - w - 1,
  2      2      2      3      2
  3v y + 3u z + (- 3w - 1)t + 3w + 3w + 4w,
  2      3      2
  6v z x + (- 6w - 3w - 1)t + 6w + 6w + 4w,
  3      3      3      4      3      2
  4v y + 4u z + (4w + 4w)t - 4w - 6w - 10w - w - 1,
  3      2      4      3      2
  8u v z x + (8w + 4w + 4w)t - 8w - 12w - 14w - 3w - 1,
  2      3      2      4      3      2
  12v z x + (12w + 12w + 8w)t - 12w - 18w - 14w - w - 1,
  3      2      4      3      2
  (- 24w - 24w - 8w)t + 24w + 36w + 26w + 7w + 1]
```

First of all, let us solve this system in the sense of Lazard by means of the REGSET constructor:

```
lts := zeroSetSplit(lp,false)$T
```

```

[{w + 1,u,v,t + 1,b1 + y + z + 2}, {w + 1,v,t + 1,z,b1 + y + 2},
 {w + 1,t + 1,z,y,b1 + 2}, {w + 1,v - u,t + 1,y + z,x,b1 + 2},
 {w + 1,u,t + 1,y,x,b1 + z + 2},

      5      4      3      2
{144w  + 216w  + 96w  + 6w  - 11w - 1,
      2      5      4      3      2
(12w  + 9w + 1)u - 72w  - 108w  - 42w  - 9w  - 3w,
      2      4      3      2
(12w  + 9w + 1)v + 36w  + 54w  + 18w ,
      3      2      4      3      2
(24w  + 24w  + 8w)t - 24w  - 36w  - 26w  - 7w - 1,

      2      2      4      3      2
(12u v - 12u )z + (12w v + 12w  + 4)t + (3w - 5)v + 36w  + 42w  + 6w
+
- 16w
,
      2
2v y + 2u z + 2w t - 2w  - w - 1,
      2      3      2
6v z x + (- 6w  - 3w - 1)t + 6w  + 6w  + 4w, b1 + y + z - t - w}
]

```

We can get the dimensions of each component
of a decomposition as follows.

```

[coHeight(ts) for ts in lts]
[3,3,3,2,2,0]

```

The first five sets have a simple shape. However, the last one, which
has dimension zero, can be simplified by using Lazard triangular sets.

Thus we call the SquareFreeRegularTriangularSet domain constructor,

```
ST := SREGSET(R,E,V,P)
```

and set the LAZM3PK package constructor to our situation.

```
pack := LAZM3PK(R,E,V,P,T,ST)
```

We are ready to solve the system by means of Lazard triangular sets:

```

zeroSetSplit(lp,false)$pack
[{w + 1,t + 1,z,y,b1 + 2}, {w + 1,v,t + 1,z,b1 + y + 2},
 {w + 1,u,v,t + 1,b1 + y + z + 2}, {w + 1,v - u,t + 1,y + z,x,b1 + 2},
 {w + 1,u,t + 1,y,x,b1 + z + 2},

      5      4      3      2      4      3      2
{144w  + 216w  + 96w  + 6w  - 11w - 1, u - 24w  - 36w  - 14w  + w + 1,

```

```

      4      3      2      4      3      2
3v - 48w - 60w - 10w + 8w + 2, t - 24w - 36w - 14w - w + 1,
      4      3      2
486z - 2772w - 4662w - 2055w + 30w + 127,
      4      3      2
2916y - 22752w - 30312w - 8220w + 2064w + 1561,
      4      3      2
356x - 3696w - 4536w - 968w + 822w + 371,
      4      3      2
2916b1 - 30600w - 46692w - 20274w - 8076w + 593}
]
```

We see the sixth triangular set is nicer now: each one of its polynomials has a constant initial.

We follow with the Vermeer example. The ordering is the usual one for this system.

Define the polynomial system.

```
f0 := (w - v) ** 2 + (u - t) ** 2 - 1
```

$$t^2 - 2ut + v^2 - 2wv + u^2 + w^2 - 1$$

```
f1 := t ** 2 - v ** 3
```

$$t^2 - v^3$$

```
f2 := 2 * t * (w - v) + 3 * v ** 2 * (u - t)
```

$$(-3v^2 - 2v + 2w)t + 3uv^2$$

```
f3 := (3 * z * v ** 2 - 1) * (2 * z * t - 1)
```

$$6vtz^2 + (-2t - 3v)z + 1$$

```
lf := [f0, f1, f2, f3]
```

$$[t^2 - 2ut + v^2 - 2wv + u^2 + w^2 - 1, t^2 - v^3, (-3v^2 - 2v + 2w)t + 3uv^2, 6vtz^2 + (-2t - 3v)z + 1]$$

First of all, let us solve this system in the sense of Kalkbrener by

means of the REGSET constructor:

```
zeroSetSplit(lf,true)$T
[
  {
    6      3      2      4
    729u  + (- 1458w  + 729w  - 4158w - 1685)u
    +
    6      5      4      3      2      2      8
    (729w  - 1458w  - 2619w  - 4892w  - 297w  + 5814w + 427)u  + 729w
    +
    7      6      5      4      3      2
    216w  - 2900w  - 2376w  + 3870w  + 4072w  - 1188w  - 1656w + 529
    ,
    4      3      2      2      6      5
    2187u  + (- 4374w  - 972w  - 12474w - 2868)u  + 2187w  - 1944w
    +
    4      3      2
    - 10125w  - 4800w  + 2501w  + 4968w - 1587
    *
    v
    +
    3      2 2      6      5      4      3      2
    (1944w  - 108w )u  + 972w  + 3024w  - 1080w  + 496w  + 1116w
    ,
    2      2      2 2      2      2
    (3v  + 2v - 2w)t - 3u v , ((4v - 4w)t - 6u v )z  + (2t + 3v )z - 1}
  ]
```

We have obtained one regular chain (regular triangular set) with dimension 1. This set is in fact a characterist set of the (radical of) of the ideal generated by the input system lf. Thus we have only the generic points of the variety associated with lf (for the elimination ordering given by ls).

So let us get now a full description of this variety.

Hence, we solve this system in the sense of Lazard by means of the REGSET constructor:

```
zeroSetSplit(lf,false)$T
[
  {
    6      3      2      4
    729u  + (- 1458w  + 729w  - 4158w - 1685)u
    +
    6      5      4      3      2      2      8
    (729w  - 1458w  - 2619w  - 4892w  - 297w  + 5814w + 427)u  + 729w
    +
```

$$\begin{aligned}
& 216w^7 - 2900w^6 - 2376w^5 + 3870w^4 + 4072w^3 - 1188w^2 - 1656w + 529 \\
& , \\
& 2187u^4 + (-4374w^3 - 972w^2 - 12474w - 2868)u^2 + 2187w^6 - 1944w^5 \\
& + \\
& - 10125w^4 - 4800w^3 + 2501w^2 + 4968w - 1587 \\
& * \\
& v \\
& + \\
& (1944w^3 - 108w^2)u^2 + 972w^6 + 3024w^5 - 1080w^4 + 496w^3 + 1116w^2 \\
& , \\
& (3v^2 + 2v - 2w)t^2 - 3uv^2, ((4v - 4w)t^2 - 6uv^2)z^2 + (2t + 3v)z^2 - 1\} \\
& , \\
& \{27w^4 + 4w^3 - 54w^2 - 36w + 23, u, (12w + 2)v - 9w^2 - 2w + 9, \\
& 6t^2 - 2v - 3w^2 + 2w + 3, 2tz - 1\} \\
& , \\
& \{59049w^6 + 91854w^5 - 45198w^4 + 145152w^3 + 63549w^2 + 60922w + 21420, \\
& 31484448266904w^5 - 18316865522574w^4 + 23676995746098w^3 \\

& * \\
& u^2 \\
& + \\
& 94262810316408w^5 - 82887296576616w^4 + 89801831438784w^3 \\
& + \\
& 28141734167208w^2 + 38070359425432w + 16003865949120 \\
& , \\
& (243w^2 + 36w + 85)v^2 + (-81u^2 - 162w^3 + 36w^2 + 154w + 72)v^3 - 72w^3 + 4w^2, \\
& (3v^2 + 2v - 2w)t^2 - 3uv^2, ((4v - 4w)t^2 - 6uv^2)z^2 + (2t + 3v)z^2 - 1\} \\
& , \\
& 4^4 \quad 3^3 \quad 2^2 \quad 2^2
\end{aligned}$$

```
{27w2 + 4w2 - 54w2 - 36w + 23, u, (12w + 2)v - 9w2 - 2w + 9,
 6t2 - 2v - 3w2 + 2w + 3, 3v z - 1}
]
```

We retrieve our regular chain of dimension 1 and we get three regular chains of dimension 0 corresponding to the degenerated cases. We want now to simplify these zero-dimensional regular chains by using Lazard triangular sets. Moreover, this will allow us to prove that the above decomposition has no redundant component.

Generally, decompositions computed by the REGSET constructor do not have redundant components. However, to be sure that no redundant component occurs one needs to use the SREGSET or LAZM3PK constructors.

So let us solve the input system in the sense of Lazard by means of the LAZM3PK constructor:

```
zeroSetSplit(lf,false)$pack
[
  {
    6      3      2      4
    729u6 + (- 1458w3 + 729w2 - 4158w - 1685)u4
  +
    6      5      4      3      2      2      8
    (729w6 - 1458w5 - 2619w4 - 4892w3 - 297w2 + 5814w + 427)u2 + 729w8
  +
    7      6      5      4      3      2
    216w7 - 2900w6 - 2376w5 + 3870w4 + 4072w3 - 1188w2 - 1656w + 529
  ,
    4      3      2      2      6      5
    2187u4 + (- 4374w3 - 972w2 - 12474w - 2868)u2 + 2187w6 - 1944w5
  +
    4      3      2

\end{aligned}$$

```

      z
    +
      3      2
    (9713133306w + 9678670317w - 16726834476w + 28144233593)u
  }
]

```

Due to square-free factorization, we obtained now four zero-dimensional regular chains. Moreover, each of them is normalized (the initials are constant). Note that these zero-dimensional components may be investigated further with the ZeroDimensionalSolvePackage package constructor.

++ [2] M. MORENO MAZA "A new algorithm for computing triangular
++ decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Description:
++ A package for solving polynomial systems by means of Lazard triangular
++ sets. This package provides two operations. One for solving in the sense
++ of the regular zeros, and the other for solving in the sense of
++ the Zariski closure. Both produce square-free regular sets.
++ Moreover, the decompositions do not contain any redundant component.
++ However, only zero-dimensional regular sets are normalized, since
++ normalization may be time consuming in positive dimension.
++ The decomposition process is that of [2].

distFact polCase

— package LEADCDET LeadingCoefDetermination —

```

)abbrev package LEADCDET LeadingCoefDetermination
++ Author : P.Gianni, May 1990
++ Description:
++ Package for leading coefficient determination in the lifting step.
++ Package working for every R euclidean with property "F".

LeadingCoefDetermination(OV,E,Z,P) : SIG == CODE where
  OV : OrderedSet
  E : OrderedAbelianMonoidSup
  Z : EuclideanDomain
  BP ==> SparseUnivariatePolynomial Z
  P : PolynomialCategory(Z,E,OV)

  NNI      ==> NonNegativeInteger
  LeadFact ==> Record(polfac:List(P),correct:Z,corrfact:List(BP))
  ParFact  ==> Record(irr:P,pow:Integer)
  FinalFact ==> Record(contp:Z,factors:List(ParFact))

SIG ==> with

polCase : (Z,NNI,List(Z)) -> Boolean
  ++ polCase(contprod, numFacts, evallcs), where contprod is the
  ++ product of the content of the leading coefficient of
  ++ the polynomial to be factored with the content of the
  ++ evaluated polynomial, numFacts is the number of factors
  ++ of the leadingCoefficient, and evallcs is the list of
  ++ the evaluated factors of the leadingCoefficient, returns
  ++ true if the factors of the leading Coefficient can be
  ++ distributed with this valuation.

distFact : (Z,List(BP),FinalFact,List(Z),List(OV),List(Z)) ->
  Union(LeadFact,"failed")
  ++ distFact(contm,unilist,plead,vl,lvar,lval), where contm is
  ++ the content of the evaluated polynomial, unilist is the list
  ++ of factors of the evaluated polynomial, plead is the complete
  ++ factorization of the leading coefficient, vl is the list
  ++ of factors of the leading coefficient evaluated, lvar is the
  ++ list of variables, lval is the list of values, returns a record
  ++ giving the list of leading coefficients to impose on the univariate
  ++ factors,

CODE ==> add

distribute: (Z,List(BP),List(P),List(Z),List(OV),List(Z)) -> LeadFact

```

```

=====
LexTriangularPackage examples
=====
```

A package for solving polynomial systems with finitely many solutions.

The decompositions are given by means of regular triangular sets. The computations use lexicographical Groebner bases. The main operations are `lexTriangular` and `squareFreeLexTriangular`. The second one provide decompositions by means of square-free regular triangular sets.

Both are based on the `lexTriangular` method described in \cite{Laza92}.

They differ from the algorithm described in \cite{Maza95} by the fact that multiplicities of the roots are not kept. With the `squareFreeLexTriangular` operation all multiplicities are removed. With the other operation some multiplicities may remain. Both operations admit an optional argument to produce normalized triangular sets.

The `LexTriangularPackage` package constructor provides an implementation of the `lexTriangular` algorithm \cite{Laza92}. This algorithm decomposes a zero-dimensional variety into zero-sets of regular triangular sets. Thus the input system must have a finite number of complex solutions. Moreover, this system needs to be a lexicographical Groebner basis.

This package takes two arguments: the coefficient-ring R of the polynomials, which must be a `GcdDomain` and their set of variables given by `ls` a List Symbol. The type of the input polynomials must be `NewSparseMultivariatePolynomial(R,V)` where V is `OrderedVariableList(ls)`. The abbreviation for `LexTriangularPackage` is `LEXTRIPK`. The main operations are `lexTriangular` and `squareFreeLexTriangular`. The later provide decompositions by means of square-free regular triangular sets, built with the `SquareFreeRegularTriangularSet` constructor, whereas the former uses the `RegularTriangularSet` constructor. Note that these constructors also implement another algorithm for solving algebraic systems by means of regular triangular sets; in that case no computations of Groebner bases are needed and the input system may have any dimension (it may have an infinite number of solutions).

The implementation of the `lexTriangular` algorithm provided in the `LexTriangularPackage` constructor differs from that reported in \cite{Maza95}.

Indeed, the `squareFreeLexTriangular` operation removes all multiplicities of the solutions (the computed solutions are pairwise different) and the `lexTriangular` operation may keep some multiplicities; this later operation runs generally faster than the former.

The interest of the `lexTriangular` algorithm is due to the following experimental remark. For some examples, a triangular decomposition of a zero-dimensional variety can be computed faster via a lexicographical Groebner basis computation than by using a direct method (like that of `SquareFreeRegularTriangularSet` and `RegularTriangularSet`). This happens typically when the total degree of the system relies essentially on its smallest variable (like in the Katsura systems). When this is not the case, the direct method may give better timings (like in the Rose system).

Of course, the direct method can also be applied to a lexicographical Groebner basis. However, the `lexTriangular` algorithm takes advantage of the structure of this basis and avoids many unnecessary computations which are performed by the direct method.

For this purpose of solving algebraic systems with a finite number of solutions, see also the `ZeroDimensionalSolvePackage`. It allows to use both strategies (the `lexTriangular` algorithm and the direct method) for computing either the complex or real roots of a system.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

Since the `LexTriangularPackage` package constructor is limited to zero-dimensional systems, it provides a `zeroDimensional?` operation to check whether this requirement holds. There is also a `groebner` operation to compute the lexicographical Groebner basis of a set of polynomials with type `NewSparseMultivariatePolynomial(R,V)`. The elimination ordering is that given by `ls` (the greatest variable being the first element of `ls`). This basis is computed by the FLGM algorithm \cite{Faug94} implemented in the `LinGroebnerPackage` package constructor.

Once a lexicographical Groebner basis is computed, then one can call the operations `lexTriangular` and `squareFreeLexTriangular`. Note that these operations admit an optional argument to produce normalized triangular sets. There is also a `zeroSetSplit` operation which does all the job from the input system; an error is produced if this system is not zero-dimensional.

Let us illustrate the facilities of the `LexTriangularPackage` constructor by a famous example, the cyclic-6 root system.

Define the coefficient ring.

```
R := Integer
```

```

Integer
                                Type: Domain

Define the list of variables,

ls : List Symbol := [a,b,c,d,e,f]
    [a,b,c,d,e,f]
                                Type: List Symbol

and make it an ordered set.

V := OVAR(ls)
    OrderedVariableList [a,b,c,d,e,f]
                                Type: Domain

Define the polynomial ring.

P := NSMP(R, V)
    NewSparseMultivariatePolynomial(Integer,OrderedVariableList [a,b,c,d,e,f])
                                Type: Domain

Define the polynomials.

p1: P :=  a*b*c*d*e*f - 1
    f e d c b a - 1
    Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [a,b,c,d,e,f])

p2: P := a*b*c*d*e + a*b*c*d*f + a*b*c*e*f + a*b*d*e*f + a*c*d*e*f + b*c*d*e*f
    (((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b
    Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [a,b,c,d,e,f])

p3: P :=  a*b*c*d + a*b*c*f + a*b*e*f + a*d*e*f + b*c*d*e + c*d*e*f
    ((d + f)c + f e)b + f e d)a + e d c b + f e d c
    Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [a,b,c,d,e,f])

p4: P := a*b*c + a*b*f + a*e*f + b*c*d + c*d*e + d*e*f
    ((c + f)b + f e)a + d c b + e d c + f e d
    Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [a,b,c,d,e,f])

p5: P := a*b + a*f + b*c + c*d + d*e + e*f
    (b + f)a + c b + d c + e d + f e
    Type: NewSparseMultivariatePolynomial(Integer,
                                OrderedVariableList [a,b,c,d,e,f])

p6: P := a + b + c + d + e + f
    a + b + c + d + e + f

```

```

Type: NewSparseMultivariatePolynomial(Integer,
                                         OrderedVariableList [a,b,c,d,e,f])

lp := [p1, p2, p3, p4, p5, p6]
[f e d c b a - 1, (((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b,
(((d + f)c + f e)b + f e d)a + e d c b + f e d c,
((c + f)b + f e)a + d c b + e d c + f e d,
(b + f)a + c b + d c + e d + f e, a + b + c + d + e + f]
Type: List NewSparseMultivariatePolynomial(Integer,
                                         OrderedVariableList [a,b,c,d,e,f])

```

Now call LEXTRIPK.

```

lextripack := LEXTRIPK(R,ls)
LexTriangularPackage(Integer,[a,b,c,d,e,f])
Type: Domain

```

Compute the lexicographical Groebner basis of the system. This may take between 5 minutes and one hour, depending on your machine.

```

lg := groebner(lp)$lextripack

      OrderedVariableList [a,b,c,d,e,f])

```

Apply lexTriangular to compute a decomposition into regular triangular sets.
This should not take more than 5 seconds.

```

    Type: List RegularChain(Integer,[a,b,c,d,e,f])

```

Note that the first set of the decomposition is normalized (all initials are integer numbers) but not the second one (normalized triangular sets are defined in the description of the `NormalizedTriangularSetCategory` constructor).

So apply now lexTriangular to produce normalized triangular sets.

```

{f - 1,e + 4f e + f ,d + e + 4f,c - f,b - f,a - f}]
Type: List RegularChain(Integer,[a,b,c,d,e,f])

```

We check that all initials are constant.

```

[ [init(p) for p in (ts :: List(P))] for ts in lts]
[[1,3,1,3,1,1], [1,1,1,1,1,1], [1,1,1,1,1,1], [1,1,1,1,1,1],
[1387545279120,1387545279120,1387545279120,1387545279120,1387545279120,1],
[1,1,1,1,1,1]]
Type: List List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])

```

Note that each triangular set in lts is a lexicographical Groebner

basis. Recall that a point belongs to the variety associated with lp if and only if it belongs to that associated with one triangular set ts in lts .

By running the `squareFreeLexTriangular` operation, we retrieve the above decomposition.

```

{f - 1, e + 4f e + f , d + e + 4f, c - f, b - f, a - f}]
Type: List SquareFreeRegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [a,b,c,d,e,f],
      OrderedVariableList [a,b,c,d,e,f],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [a,b,c,d,e,f]))

```

Thus the solutions given by lts are pairwise different.

We count them as follows.

```
reduce(+,[degree(ts) for ts in lts])
156
Type: PositiveInteger
```

We can investigate the triangular decomposition lts by using the ZeroDimensionalSolvePackage.

This requires to add an extra variable (smaller than the others) as follows.

```
ls2 : List Symbol := concat(ls,new()$Symbol)
[a,b,c,d,e,f,%A]
Type: List Symbol
```

Then we call the package.

```
zdpack := ZDSOLVE(R,ls,ls2)
(20) ZeroDimensionalSolvePackage(Integer,[a,b,c,d,e,f],[a,b,c,d,e,f,%A])
Type: Domain
```

We compute a univariate representation of the variety associated with the input system as follows.

```
concat [univariateSolve(ts)$zdpack for ts in lts]
[

coordinates: List Polynomial Integer)

```

Since the univariateSolve operation may split a regular set, it returns a list. This explains the use of concat.

Look at the last item of the result. It consists of two parts. For any complex root ? of the univariate polynomial in the first part, we get a tuple of univariate polynomials (in a, ..., f respectively) by replacing %A by ? in the second part. Each of these tuples t describes a point of the variety associated with lp by equaling to zero the polynomials in t.

Note that the way of reading these univariate representations is explained also in the example illustrating the ZeroDimensionalSolvePackage constructor.

Now, we compute the points of the variety with real coordinates.

```
concat [realSolve(ts)$zdpack for ts in lts]

Type: List List RealClosure Fraction Integer

We obtain 24 points given by lists of elements in the RealClosure of Fraction of R. In each list, the first value corresponds to the indeterminate f, the second to e and so on.

++ Faugere Efficient Computation of Zero-Dimensional Groebner Bases by Change
++ of Ordering
++ Description:
++ A package for solving polynomial systems with finitely many solutions.
++ The decompositions are given by means of regular triangular sets.
++ The computations use lexicographical Groebner bases.
++ The main operations are lexTriangular
++ and squareFreeLexTriangular. The second one provide decompositions by
++ means of square-free regular triangular sets.
++ Both are based on the lexTriangular method described in [1].
++ They differ from the algorithm described in [2] by the fact that
++ multiplicities of the roots are not kept.
++ With the squareFreeLexTriangular operation all multiplicities are removed.
++ With the other operation some multiplicities may remain. Both operations
++ admit an optional argument to produce normalized triangular sets.

SIG ==> with

zeroDimensional? : LP -> B
++ \axiom{zeroDimensional?(lp)} returns true iff
++ \axiom{lp} generates a zero-dimensional ideal
++ w.r.t. the variables involved in \axiom{lp}.

fglmIfCan : LP -> Union(LP, "failed")
++ \axiom{fglmIfCan(lp)} returns the lexicographical Groebner
++ basis of \axiom{lp} by using the FGLM strategy,
++ if \axiom{zeroDimensional?(lp)} holds .

groebner : LP -> LP
++ \axiom{groebner(lp)} returns the lexicographical Groebner
++ basis of \axiom{lp}. If \axiom{lp} generates a zero-dimensional
++ ideal then the FGLM strategy is used, otherwise
++ the Sugar strategy is used.

lexTriangular : (LP, B) -> List TS
++ \axiom{lexTriangular(base, norm?)} decomposes the variety
++ associated with \axiom{base} into regular chains.
++ Thus a point belongs to this variety iff it is a regular

```

```

++ zero of a regular set in in the output.
++ Note that \axiom{base} needs to be a lexicographical Groebner basis
++ of a zero-dimensional ideal. If \axiom{norm?} is \axiom{true}
++ then the regular sets are normalized.

```

```

squareFreeLexTriangular : (LP, B) -> List ST
++ \axiom{squareFreeLexTriangular(base, norm?) } decomposes the variety
++ associated with \axiom{base} into square-free regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \axiom{base} needs to be a lexicographical Groebner basis
++ of a zero-dimensional ideal. If \axiom{norm?} is \axiom{true}
++ then the regular sets are normalized.

```

```

zeroSetSplit : (LP, B) -> List TS
++ \axiom{zeroSetSplit(lp, norm?) } decomposes the variety
++ associated with \axiom{lp} into regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
++ If \axiom{norm?} is \axiom{true} then the regular sets
++ are normalized.

```

```

zeroSetSplit : (LP, B) -> List ST
++ \axiom{zeroSetSplit(lp, norm?) } decomposes the variety
++ associated with \axiom{lp} into square-free regular chains.
++ Thus a point belongs to this variety iff it is a regular
++ zero of a regular set in in the output.
++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
++ If \axiom{norm?} is \axiom{true} then the regular sets
++ are normalized.

o)show LinesOpPack

LinesOpPack (LOP)

— package LOP LinesOpPack —

```

)abbrev package LOP LinesOpPack
++ Authors: G. Hache
++ Date Created: 21 sept 1994
++ Date Last Updated: May 2010 by Tim Daly
++ Description:
++ A package that exports several linear algebra operations over lines
++ of matrices. Part of the PAFF package.

LinesOpPack(K) : SIG == CODE where
  K:Field

SIG ==> with

  rowEchWoZeroLinesWOVectorise : Matrix(K) -> Matrix(K)

  rowEchWoZeroLines : Matrix(K) -> Matrix(K)

  reduceRow : List(List(K)) -> List(List(K))
    ++ reduceRow(llk) if the input is considered as a matrix, the output would
    ++ be the row reduction matrix. It's almost the rowEchelon form
    ++ except that no permutation of lines is performed.

  quotVecSpaceBasis : (List(List(K)),List(List(K))) -> List(List(K))
    ++ quotVecSpaceBasis(b1,b2) returns a basis of V1/V2 where
    ++ V1 and V2 are vector space with basis b1 and b2 resp. and
    ++ V2 is suppose to be include in V1; Note that if
  
```

```

++ it is not the case then it returns the basis of V1/W
++ where W = intersection of V1 and V2

reduceLineOverLine : (List(K),List(K),K) -> List(K)
++reduceLineOverLine(v1,v2,a) returns v1-a*v1 where
++ v1 and v2 are considered as vector space.

reduceRowOnList : (List(K),List(List(K))) -> List(List(K))
++ reduceRowOnList(v,lvec) applies a row reduction on each of the
++ element of lv using v according to a pivot in v which is set to
++ be the first non nul element in v.

ListFunctions2 (LIST2)

Exports:

map reduce scan

— package LIST2 ListFunctions2 —

```

)abbrev package LIST2 ListFunctions2
++ Description:
++ \spadtype{ListFunctions2} implements utility functions that
++ operate on two kinds of lists, each with a possibly different
++ type of element.

ListFunctions2(A,B) : SIG == CODE where
  A : Type
  B : Type

  LA    ==> List A
  LB    ==> List B
  O2    ==> FiniteLinearAggregateFunctions2(A, LA, B, LB)

SIG ==> with

  scan : ((A, B) -> B, LA, B) -> LB
    ++ scan(fn,u,ident) successively uses the binary function
    ++ \spad{fn} to reduce more and more of list \spad{u}.
    ++ \spad{ident} is returned if the \spad{u} is empty.
    ++ The result is a list of the reductions at each step. See
    ++ \spadfun{reduce} for more information. Examples:
    ++ \spad{scan(fn,[1,2],0) = [fn(2,fn(1,0)),fn(1,0)]} and
    ++ \spad{scan(*,[2,3],1) = [2 * 1, 3 * (2 * 1)]}.

  reduce : ((A, B) -> B, LA, B) -> B
    ++ reduce(fn,u,ident) successively uses the binary function
    ++ \spad{fn} on the elements of list \spad{u} and the result
    ++ of previous applications. \spad{ident} is returned if the
    ++ \spad{u} is empty. Note the order of application in
    ++ the following examples:
    ++ \spad{reduce(fn,[1,2,3],0) = fn(3,fn(2,fn(1,0)))} and
    ++ \spad{reduce(*,[2,3],1) = 3 * (2 * 1)}.

  map : (A -> B, LA) -> LB
    ++ map(fn,u) applies \spad{fn} to each element of
    ++ list \spad{u} and returns a new list with the results.
    ++ For example \spad{map(square,[1,2,3]) = [1,4,9]}.

=====
ListToMap examples
=====

ListToMap allows mappings to be described by a pair of lists of equal lengths. The image of an element x , which appears in position n in the first list, is then the n -th element of the second list. A default value or default function can be specified to be used when x does not appear in the first list. In the absence of defaults, an error will occur in that case.

See Also:
o)show ListToMap

ListToMap (LIST2MAP)**Exports:**

match

— package LIST2MAP ListToMap —

```

)abbrev package LIST2MAP ListToMap
++ Author: Manuel Bronstein
++ Date Created: 22 Mar 1988
++ Change History:11 Oct 1989
++ Description:
++ \spadtype{ListToMap} allows mappings to be described by a pair of
++ lists of equal lengths. The image of an element \spad{x},
++ which appears in position \spad{n} in the first list, is then
++ the \spad{n}th element of the second list. A default value or
++ default function can be specified to be used when \spad{x}
++ does not appear in the first list. In the absence of defaults,
++ an error will occur in that case.

ListToMap(A,B) : SIG == CODE where
  A : SetCategory
  B : Type

  LA ==> List A
  LB ==> List B
  AB ==> (A -> B)

  SIG ==> with

    match : (LA, LB) -> AB
      ++ match(la, lb) creates a map with no default source or target values
      ++ defined by lists la and lb of equal length.
      ++ The target of a source value \spad{x} in la is the
      ++ value y with the same index lb.
      ++ Error: if la and lb are not of equal length.
      ++ Note that when this map is applied, an error occurs when
  
```

```

++ applied to a value missing from la.

match : (LA, LB, A) -> B
++ match(la, lb, a) creates a map
++ defined by lists la and lb of equal length, where \spad{a} is used
++ as the default source value if the given one is not in \spad{la}.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Error: if la and lb are not of equal length.

match : (LA, LB, B) -> AB
++ match(la, lb, b) creates a map
++ defined by lists la and lb of equal length, where \spad{b} is used
++ as the default target value if the given function argument is
++ not in \spad{la}.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Error: if la and lb are not of equal length.

match : (LA, LB, A, B) -> B
++ match(la, lb, a, b) creates a map
++ defined by lists la and lb of equal length.
++ and applies this map to a.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Argument b is the default target value if a is not in la.
++ Error: if la and lb are not of equal length.

match : (LA, LB, AB) -> AB
++ match(la, lb, f) creates a map
++ defined by lists la and lb of equal length.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Argument \spad{f} is used as the
++ function to call when the given function argument is not in
++ \spad{la}.
++ The value returned is f applied to that argument.

match : (LA, LB, A, AB) -> B
++ match(la, lb, a, f) creates a map
++ defined by lists la and lb of equal length.
++ and applies this map to a.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Argument \spad{f} is a default function to call if a is not in la.
++ The value returned is then obtained by applying f to argument a.

  pointToPlace : (ProjPt,PolyRing) -> Plc
    ++ pointToPlace(pt,pol) takes for input a simple point pt on the curve
    ++ defined by pol and set the local parametrization of the point.

  localParamOfSimplePt : (ProjPt,PolyRing,Integer) -> List PCS
    ++ localParamOfSimplePt(pt,pol,n) computes the local parametrization
    ++ of the simple point pt on the curve defined by pol. This local
    ++ parametrization is done according to the standard open affine
    ++ plane set by n

  pointDominateBy : Plc -> ProjPt
    ++ pointDominateBy(pl) returns the projective point dominated
    ++ by the place pl.

  localize : (PolyRing,ProjPt,PolyRing,Integer) -> _
    Record(fnc:PolyRing,crv:PolyRing,chart:List(Integer))
    ++ localize(f,pt,crv,n) returns a record containing the polynomials f
    ++ and crv translate to the origin with respect to pt. The last
    ++ element of the records, consisting of three integers contains
    ++ information about the local parameter that will be used
    ++ (either x or y): the first integer correspond to the variable
    ++ that will be used as a local parameter.

=====

MakeBinaryCompiledFunction examples

=====

Tools and transforms for making compiled functions from top-level expressions.

Given an expression assigned to a variable we can turn it into a function of two arguments.

First, we create the domain we need:

```
MBCF:=MakeBinaryCompiledFunction(POLY(FRAC(INT)),FLOAT,FLOAT,FLOAT)
```

Next, we have the expression we want to convert:

```
f:=(x+3)*(y+4)
```

We use `compiledFunction` to do the conversion. The first argument is the variable holding the expression. The second and third arguments are the names of variables in the expression.

```
g:=compiledFunction(f,x,y)$MBCF
```

This created a function `g(x,y)` which we can evaluate:

```
g(2.0,3.0) ==> 35.0
```

MakeFunction examples

=====

Tools for making interpreter functions from top-level expressions
 Transforms top-level objects into interpreter functions.

It is sometimes useful to be able to define a function given by
 the result of a calculation.

Suppose that you have obtained the following expression after several
 computations and that you now want to tabulate the numerical values of
 f for x between -1 and +1 with increment 0.1.

```
expr := (x - exp x + 1)^2 * (sin(x^2) * x + 1)^3
```

```

      3   x 2      4   3   x   5   4   3   2 3
      (x (%e ) + (- 2x - 2x )%e + x + 2x + x )sin(x )
+
      2   x 2      3   2   x   4   3   2   2 2
      (3x (%e ) + (- 6x - 6x )%e + 3x + 6x + 3x )sin(x )
+
      x 2      2   x   3   2   2   x 2
      (3x (%e ) + (- 6x - 6x)%e + 3x + 6x + 3x)sin(x ) + (%e )
+
      x 2
      (- 2x - 2)%e + x + 2x + 1
Type: Expression Integer

```

You could, of course, use the function `eval` within a loop and evaluate `expr` twenty-one times, but this would be quite slow. A better way is to create a numerical function `f` such that `f(x)` is defined by the expression `expr` above, but without retyping `expr`! The package `MakeFunction` provides the operation function which does exactly this.

Issue this to create the function `f(x)` given by `expr`.

```

function(expr, f, x)
f
Type: Symbol

```

To tabulate `expr`, we can now quickly evaluate `f` 21 times.

```

tbl := [f(0.1 * i - 1) for i in 0..20];
Type: List Float

```

Use the list `[x1,...,xn]` as the third argument to `function` to create a multivariate function `f(x1,...,xn)`.

```

e := (x - y + 1)^2 * (x^2 * y + 1)^2
      4 4      5 4      2 3      6 5      4 3      2 2
      x y + (- 2x - 2x + 2x )y + (x + 2x + x - 4x - 4x + 1)y
+
      4 3      2 2
      (2x + 4x + 2x - 2x - 2)y + x + 2x + 1
Type: Polynomial Integer

function(e, g, [x, y])
g
Type: Symbol

```

In the case of just two variables, they can be given as arguments without making them into a list.

```

function(e, h, x, y)
h

```

Type: Symbol

Note that the functions created by function are not limited to floating point numbers, but can be applied to any type for which they are defined.

```
m1 := squareMatrix [ [1, 2], [3, 4] ]
+1 2+
|  |
+3 4+
```

Type: SquareMatrix(2,Integer)

```
m2 := squareMatrix [ [1, 0], [-1, 1] ]
+ 1 0+
|  |
+- 1 1+
```

Type: SquareMatrix(2,Integer)

```
h(m1, m2)
+- 7836 8960 +
|  |
+- 17132 19588+
```

Type: SquareMatrix(2,Integer)

=====
MakeUnaryCompiledFunction examples
=====

```

Tools for making compiled functions from top-level expressions
Transforms top-level objects into compiled functions.

Given an expression assigned to a variable we can turn it into a
function of one argument.

First, we create the domain we need:

```
MUCF:=MakeUnaryCompiledFunction(POLY(FRAC(INT)),FLOAT,FLOAT)
```

Next, we have the expression we want to convert:

```
f:=(x+3)*^2
```

We use compiledFunction to do the conversion. The first argument is
the variable holding the expression. The second argument is the
names of variable in the expression.

```
g:=compiledFunction(f,x)$MUCF
```

This created a function g(x,y) which we can evaluate:

```
g(2.0) ==> 25.0
```

=====
MappingPackage1 examples
=====
```

Various Currying operations.

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

```
power(q: FRAC INT, n: INT): FRAC INT == q**n
                                Type: Void
```

```
power(2,3)
8
                                Type: Fraction Integer
```

The twist operation transposes the arguments of a binary function. Here rewop(a, b) is power(b, a).

```
rewop := twist power
theMap(MAPPKG3;twist;MM;5!0)
                                Type: ((Integer,Fraction Integer) -> Fraction Integer)
```

This is 2³.

```
rewop(3, 2)
8
                                Type: Fraction Integer
```

Now we define square in terms of power.

```
square: FRAC INT -> FRAC INT
```

Type: Void

The curryRight operation creates a unary function from a binary one by providing a constant argument on the right.

```
square:= curryRight(power, 2)
  theMap(MAPPKG3;curryRight;MBM;1!0,0)
      Type: (Fraction Integer -> Fraction Integer)
```

Likewise, the curryLeft operation provides a constant argument on the left.

```
square 4
16
      Type: Fraction Integer
```

The constantRight operation creates (in a trivial way) a binary function from a unary one: constantRight(f) is the function g such that $g(a,b) = f(a)$.

```
squirrel:= constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
  theMap(MAPPKG3;constantRight;MM;3!0)
      Type: ((Fraction Integer,Fraction Integer) -> Fraction Integer)
```

Likewise, constantLeft(f) is the function g such that $g(a,b) = f(b)$.

```
squirrel(1/2, 1/3)
1
-
4
      Type: Fraction Integer
```

The curry operation makes a unary function nullary.

```
sixteen := curry(square, 4/1)
  theMap(MAPPKG2;curry;MAM;2!0,0)
      Type: (() -> Fraction Integer)
```

```
sixteen()
16
      Type: Fraction Integer
```

The * operation constructs composed functions.

```
square2:=square*square
  theMap(MAPPKG3;*;MMM;6!0,0)
      Type: (Fraction Integer -> Fraction Integer)
```

```
square2 3
81
      Type: Fraction Integer
```

Use the `**` operation to create functions that are n-fold iterations of other functions.

```
sc(x: FRAC INT): FRAC INT == x + 1
Type: Void
```

This is a list of Mapping objects.

```
incfns := [sc**i for i in 0..10]
[theMap(MAPPKG1;**MNniM;6!0,0), theMap(MAPPKG1;**MNniM;6!0,0),
 theMap(MAPPKG1;**MNniM;6!0,0), theMap(MAPPKG1;**MNniM;6!0,0),
 theMap(MAPPKG1;**MNniM;6!0,0), theMap(MAPPKG1;**MNniM;6!0,0),
 theMap(MAPPKG1;**MNniM;6!0,0), theMap(MAPPKG1;**MNniM;6!0,0),
 theMap(MAPPKG1;**MNniM;6!0,0), theMap(MAPPKG1;**MNniM;6!0,0),
 theMap(MAPPKG1;**MNniM;6!0,0)]
Type: List (Fraction Integer -> Fraction Integer)
```

This is a list of applications of those functions.

```
[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
Type: List Fraction Integer
```

Use the `recur` operation for recursion:

```
g := recur f means g(n,x) == f(n,f(n-1,...f(1,x))).

times(n:NNI, i:INT):INT == n*i
Type: Void

r := recur(times)
theMap(MAPPKG1;recur;2M;7!0,0)
Type: ((NonNegativeInteger,Integer) -> Integer)
```

This is a factorial function.

```
fact := curryRight(r, 1)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
Type: (NonNegativeInteger -> Integer)

fact 4
24
Type: PositiveInteger
```

Constructed functions can be used within other functions.

```
mtto2ton(m, n) ==
  raiser := square^n
  raiser m
```

Type: Void

This is $3^{(2^3)}$.

```
mto2ton(3, 3)
6561
```

Type: Fraction Integer

Here shiftfib is a unary function that modifies its argument.

```
shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t
```

Type: Void

By currying over the argument we get a function with private state.

```
fibinit: List INT := [0, 1]
[0,1]
```

Type: List Integer

```
fibs := curry(shiftfib, fibinit)
  theMap(MAPPKG2;curry;MAM;2!0,0)
Type: (() -> Integer)
```

```
[fibs() for i in 0..30]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597,
 2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418,
 317811, 514229, 832040]
```

Type: List Integer

=====
MappingPackage2 examples
=====

```

Various Currying operations.

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

```

power(q: FRAC INT, n: INT): FRAC INT == q**n
Type: Void

```

```

power(2,3)
8
Type: Fraction Integer

```

The twist operation transposes the arguments of a binary function. Here rewop(a, b) is power(b, a).

```

rewop := twist power
theMap(MAPPKG3;twist;MM;5!0)
Type: ((Integer,Fraction Integer) -> Fraction Integer)

```

This is 2^3 .

```
rewop(3, 2)
8
Type: Fraction Integer
```

Now we define square in terms of power.

```
square: FRAC INT -> FRAC INT
Type: Void
```

The `curryRight` operation creates a unary function from a binary one by providing a constant argument on the right.

```
square:= curryRight(power, 2)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
Type: (Fraction Integer -> Fraction Integer)
```

Likewise, the `curryLeft` operation provides a constant argument on the left.

```
square 4
16
Type: Fraction Integer
```

The `constantRight` operation creates (in a trivial way) a binary function from a unary one: `constantRight(f)` is the function g such that $g(a,b) = f(a)$.

```
squirrel:= constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
theMap(MAPPKG3;constantRight;MM;3!0)
Type: ((Fraction Integer,Fraction Integer) -> Fraction Integer)
```

Likewise, `constantLeft(f)` is the function g such that $g(a,b) = f(b)$.

```
squirrel(1/2, 1/3)
1
-
4
Type: Fraction Integer
```

The `curry` operation makes a unary function nullary.

```
sixteen := curry(square, 4/1)
theMap(MAPPKG2;curry;MAM;2!0,0)
Type: (() -> Fraction Integer)
```

```
sixteen()
16
Type: Fraction Integer
```

The `*` operation constructs composed functions.

```
square2:=square*square
  theMap(MAPPKG3;*;MMM;6!0,0)
      Type: (Fraction Integer -> Fraction Integer)

square2 3
  81
      Type: Fraction Integer
```

Use the `**` operation to create functions that are n-fold iterations of other functions.

```
sc(x: FRAC INT): FRAC INT == x + 1
      Type: Void
```

This is a list of Mapping objects.

```
incfns := [sc**i for i in 0..10]
[theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0)]
      Type: List (Fraction Integer -> Fraction Integer)
```

This is a list of applications of those functions.

```
[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
      Type: List Fraction Integer
```

Use the `recur` operation for recursion:

```
g := recur f means g(n,x) == f(n,f(n-1,...f(1,x))).

times(n:NNI, i:INT):INT == n*i
      Type: Void

r := recur(times)
  theMap(MAPPKG1;recur;2M;7!0,0)
      Type: ((NonNegativeInteger,Integer) -> Integer)
```

This is a factorial function.

```
fact := curryRight(r, 1)
  theMap(MAPPKG3;curryRight;MBM;1!0,0)
      Type: (NonNegativeInteger -> Integer)
```

```
fact 4
  24
                                Type: PositiveInteger
```

Constructed functions can be used within other functions.

```
mto2ton(m, n) ==
  raiser := square^n
  raiser m
                                Type: Void
```

This is $3^{(2^3)}$.

```
mto2ton(3, 3)
  6561
                                Type: Fraction Integer
```

Here shiftfib is a unary function that modifies its argument.

```
shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t
                                Type: Void
```

By currying over the argument we get a function with private state.

```
fibinit: List INT := [0, 1]
  [0,1]
                                Type: List Integer

fibs := curry(shiftfib, fibinit)
  theMap(MAPPKG2;curry;MAM;2!0,0)
                                Type: (() -> Integer)
```

```
[fibs() for i in 0..30]
  [0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597,
  2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418,
  317811, 514229, 832040]
                                Type: List Integer
```

=====

MappingPackage3 examples

=====

Various Currying operations.

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

```
power(q: FRAC INT, n: INT): FRAC INT == q**n
                                Type: Void
```

```
power(2,3)
8
                                Type: Fraction Integer
```

The twist operation transposes the arguments of a binary function. Here `rewop(a, b)` is `power(b, a)`.

```
rewop := twist power
      theMap(MAPPKG3;twist;MM;5!0)
                                Type: ((Integer,Fraction Integer) -> Fraction Integer)
```

This is 2^3 .

```
rewop(3, 2)
8
                                Type: Fraction Integer
```

Now we define square in terms of power.

```
square: FRAC INT -> FRAC INT
                                Type: Void
```

The `curryRight` operation creates a unary function from a binary one by providing a constant argument on the right.

```
square:= curryRight(power, 2)
      theMap(MAPPKG3;curryRight;MBM;1!0,0)
                                Type: (Fraction Integer -> Fraction Integer)
```

Likewise, the `curryLeft` operation provides a constant argument on the left.

```
square 4
16
                                Type: Fraction Integer
```

The `constantRight` operation creates (in a trivial way) a binary function from a unary one: `constantRight(f)` is the function `g` such that `g(a,b)= f(a)`.

```
squirrel:= constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
      theMap(MAPPKG3;constantRight;MM;3!0)
                                Type: ((Fraction Integer,Fraction Integer) -> Fraction Integer)
```

Likewise, `constantLeft(f)` is the function `g` such that `g(a,b)= f(b)`.

```
squirrel(1/2, 1/3)
1
-
4
Type: Fraction Integer
```

The curry operation makes a unary function nullary.

[illegible]

```
sixteen()
16
Type: Fraction Integer
```

The `*` operation constructs composed functions.

```
square2:=square*square
  theMap(MAPPKG3;*;MMM;6!0,0)
      Type: (Fraction Integer -> Fraction Integer)
```

```
square2 3
      81
Type: Fraction Integer
```

Use the `**` operation to create functions that are n-fold iterations of other functions.

```
sc(x: FRAC INT): FRAC INT == x + 1
                        Type: Void
```

This is a list of Mapping objects.

```
incfns := [sc**i for i in 0..10]
[theMap(MAPPKG1;**MNnIM;6!0,0), theMap(MAPPKG1;**MNnIM;6!0,0),
theMap(MAPPKG1;**MNnIM;6!0,0), theMap(MAPPKG1;**MNnIM;6!0,0),
theMap(MAPPKG1;**MNnIM;6!0,0), theMap(MAPPKG1;**MNnIM;6!0,0),
theMap(MAPPKG1;**MNnIM;6!0,0), theMap(MAPPKG1;**MNnIM;6!0,0),
theMap(MAPPKG1;**MNnIM;6!0,0), theMap(MAPPKG1;**MNnIM;6!0,0),
theMap(MAPPKG1;**MNnIM;6!0,0)]
Type: List (Fraction Integer -> Fraction Integer)
```

This is a list of applications of those functions.

```
[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
Type: List Fraction Integer
```

Use the recur operation for recursion:

```
g := recur f means g(n,x) == f(n,f(n-1,...f(1,x))).

times(n:NNI, i:INT):INT == n*i
                        Type: Void

r := recur(times)
  theMap(MAPPKG1;recur;2M;7!0,0)
                        Type: ((NonNegativeInteger,Integer) -> Integer)
```

This is a factorial function.

```
fact := curryRight(r, 1)
  theMap(MAPPKG3;curryRight;MBM;1!0,0)
                        Type: (NonNegativeInteger -> Integer)

fact 4
  24
                        Type: PositiveInteger
```

Constructed functions can be used within other functions.

```
mto2ton(m, n) ==
  raiser := square^n
  raiser m
                        Type: Void
```

This is $3^{(2^3)}$.

```
mto2ton(3, 3)
  6561
                        Type: Fraction Integer
```

Here shiftfib is a unary function that modifies its argument.

```
shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t
                        Type: Void
```

By currying over the argument we get a function with private state.

```
fibinit: List INT := [0, 1]
  [0,1]
                        Type: List Integer

fibs := curry(shiftfib, fibinit)
```

```

theMap(MAPPKG2;curry;MAM;2!0,0)
      Type: (()) -> Integer

[fibs() for i in 0..30]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597,
 2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418,

MappingPackage examples

=====

Given functions f and g, returns the applicable closure

We can construct some simple maps that take a variable x
into an equation:

```

p:=(x:EXPR(INT)):EXPR(INT)+->3*x
q:=(x:EXPR(INT)):EXPR(INT)+->2*x+3

```

Now we can do the four arithmetic operations, +, -, *, / on these
newly constructed mappings. Since the maps are from the domain
Expression Integer to the same domain we can also use symbolic
values for the argument. All of the following will return 0,
showing that function composition is equivalent to the result
of doing the operations individually.

```

(p+q)(4)-(p(4)+q(4))
(p+q)(x)-(p(x)+q(x))

```

```

(p-q)(4)-(p(4)-q(4))
(p-q)(x)-(p(x)-q(x))

```

```

(p*q)(4)-(p(4)*q(4))
(p*q)(x)-(p(x)*q(x))

```

```
(p/q)(4)-(p(4)/q(4))
(p/q)(x)-(p(x)/q(x))
```

We can construct simple maps from Integer to Integer but this limits our ability to do division.

```
r:=(x:INT):INT+> (x*x*x)
s:=(y:INT):INT+> (y*y+3)
```

Again, all of these will return 0:

```
(r+s)(4)-(r(4)+s(4))
(r-s)(4)-(r(4)-s(4))
(r*s)(4)-(r(4)*s(4))
```

If we want to do division with Integer inputs we create the appropriate map:

```
t:=(x:INT):EXPR(INT)+> (x*x*x)
u:=(y:INT):EXPR(INT)+> (y*y+3)

(t/u)(4)-(t(4)/u(4))
```

We can even recover the original functions if we make a map that always returns the constant 1:

```
h:=(x:EXPR(INT)):EXPR(INT)+>1

theMap(Closure)
      Type: (Expression Integer -> Expression Integer)

(p/h)(x)

      3x
                                     Type: Expression Integer
(q/h)(x)

      2x + 3
                                     Type: Expression Integer
```

=====

MatrixManipulation examples

=====

Some functions for manipulating (dense) matrices.

Supported are various kinds of slicing, splitting and stacking of matrices. The functions resemble operations often used in numerical linear algebra algorithms.

```
M := matrix([[a,b,c],[d,e,f],[g,h,i]])
```

```
+a  b  c+
|      |
|d  e  f|
|      |
+g  h  i+
```

```
element(M, 2,2)
```

```
[e]
```

```
aRow(M, 1)
```

```
[a  b  c]
```

```
aRow(M, 2)
```

```
[d  e  f]
```

```
aColumn(M, 2)
```

```
+b+
| |
|e|
| |
+h+
```

```
aColumn(M, 3)
```

```
+c+
```

```

| |
|f|
| |
+i+

```

```
rows(M, [1,2])
```

```

+a b c+
|   |
+d e f+

```

```
rows(M, [1,3])
```

```

+a b c+
|   |
+g h i+

```

```
rows(M, [3,2])
```

```

+g h i+
|   |
+d e f+

```

```
rows(M, 2..3)
```

```

+d e f+
|   |
+g h i+

```

```
columns(M, [1,2])
```

```

+a b+
|   |
|d e|
|   |
+g h+

```

```
columns(M, [1,3])
```

```

+a c+
|   |
|d f|
|   |
+g i+

```

```
columns(M, [3,2])
```

```

+c b+
|   |
|f e|

```

$$\begin{array}{cc} | & | \\ +i & h+ \end{array}$$

columns(M, 1..2)

```

=====
element from MatrixManipulation (MAMA)
=====

```

```

NAME
=====

```

```

    element

```

```

DOMAIN
=====

```

```

    MatrixManipulation (MAMA)

```

SYNOPSIS

=====

```
element : (M, PositiveInteger, PositiveInteger) -> M
```

```
where
```

```
  R : Field
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M : MatrixCategory(R, Row, Col)
```

DESCRIPTION

=====

element returns a single element out of a matrix.
The element is put into a one by one matrix.

ARGUMENTS

=====

The first argument is an element of M

```
where
```

```
  R : Field
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M : MatrixCategory(R, Row, Col)
```

The second element is a member of PositiveInteger

The third element is a member of PositiveInteger

RETURN VALUE

=====

The result is an element of M

```
where
```

```
  R : Field
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M : MatrixCategory(R, Row, Col)
```

EXAMPLES

=====

```
M := matrix([[a,b,c],[d,e,f],[g,h,i]])
```

```
element(M,2,2)
```

NOTES

aRow from MatrixManipulation (MAMA)

=====

NAME

=====

aRow

DOMAIN

=====

MatrixManipulation (MAMA)

SYNOPSIS

=====

aRow : (M, PositiveInteger) -> M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

DESCRIPTION

=====

aRow returns a single row out of a matrix.
 The row is put into a one by N matrix.

ARGUMENTS

=====

The first argument is an element of M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

The second element is a member of PositiveInteger

RETURN VALUE

=====

The result is an element of M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

EXAMPLES

=====

M := matrix([[a,b,c],[d,e,f],[g,h,i]])

aRow(M, 1)

aRow(M, 2)

diagonalMatrix

DOMAIN

=====

MatrixManipulation (MAMA)

SYNOPSIS

=====

diagonalMatrix : (M, Integer) -> M
 diagonalMatrix : M -> M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

DESCRIPTION

=====

diagonalMatrix : (M, Integer) -> M

diagonalMatrix returns a diagonal out of a matrix.
 The diagonal is put into a matrix of same shape as the
 original one. Positive integer arguments select upper
 off-diagonals, negative ones lower off-diagonals.

diagonalMatrix : M -> M

diagonalMatrix returns the main diagonal out of
 a matrix. The diagonal is put into a matrix of same shape
 as the original one.

ARGUMENTS

=====

diagonalMatrix : (M, Integer) -> M

The first argument is an element of M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

The second element is an Integer

`diagonalMatrix : M -> M`

The first argument is an element of M

where

`R : Field`
`Row : FiniteLinearAggregate R`
`Col : FiniteLinearAggregate R`
`M : MatrixCategory(R, Row, Col)`

RETURN VALUE

=====

The result is an element of M

where

`R : Field`
`Row : FiniteLinearAggregate R`
`Col : FiniteLinearAggregate R`
`M : MatrixCategory(R, Row, Col)`

EXAMPLES

=====

`M := matrix([[a,b,c],[d,e,f],[g,h,i]])`

`diagonalMatrix(M, 1)`

`diagonalMatrix(M, 2)`

`diagonalMatrix(M, -1)`

`diagonalMatrix(M)`

MatrixManipulation (MAMA)

SYNOPSIS

=====

blockSplit : (M, PositiveInteger, PositiveInteger) -> List List M

blockSplit : (M, List PositiveInteger, PositiveInteger) -> List List M

blockSplit : (M, PositiveInteger, List PositiveInteger) -> List List M

blockSplit : (M, List PositiveInteger, List PositiveInteger) -> List List M

where

R : Field

Row : FiniteLinearAggregate R

Col : FiniteLinearAggregate R

M : MatrixCategory(R, Row, Col)

DESCRIPTION

=====

blockSplit splits a matrix into multiple submatrices row and column wise, dividing a matrix into blocks.

ARGUMENTS

=====

`blockSplit : (M, PositiveInteger, PositiveInteger) -> List List M`

The first argument is an element of M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

The second argument is a PositiveInteger

The third argument is a PositiveInteger

`blockSplit : (M, List PositiveInteger, PositiveInteger) -> List List M`

The first argument is an element of M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

The second argument is a List of PositiveInteger

The third argument is a PositiveInteger

`blockSplit : (M, PositiveInteger, List PositiveInteger) -> List List M`

The first argument is an element of M

where

R : Field
 Row : FiniteLinearAggregate R
 Col : FiniteLinearAggregate R
 M : MatrixCategory(R, Row, Col)

The second argument is a PositiveInteger

The third argument is a List of PositiveInteger

`blockSplit : (M, List PositiveInteger, List PositiveInteger) -> List List M`

The first argument is an element of M

where

R : Field
 Row : FiniteLinearAggregate R

```
Col : FiniteLinearAggregate R
M : MatrixCategory(R, Row, Col)
```

The second argument is a List of PositiveInteger

The third argument is a List of PositiveInteger

RETURN VALUE

=====

The result is an List of Lists of elements of M

where

```
R : Field
Row : FiniteLinearAggregate R
Col : FiniteLinearAggregate R
M : MatrixCategory(R, Row, Col)
```

EXAMPLES

=====

```
E := matrix([[i,a,b,c],[a,a,b,c],[b,d,e,f],[c,g,h,i]])
```

```
t1:= blockSplit(E,2,2)
```

```
t2:= blockSplit(E, [2,1,1], 2)
```

```
t3:= blockSplit(E, 4, [2,2])
```

```
t4:= blockSplit(E, [1,2,1], [2,2])

MatrixManipulation (MAMA)

— package MAMA MatrixManipulation —

```
)abbrev package MAMA MatrixManipulation
++ Author: Raoul Bourquin
++ Date Created: 17 November 2012
++ Date Last Updated: 1 December 2012
++ Description:
++ Some functions for manipulating (dense) matrices.
++ Supported are various kinds of slicing, splitting and stacking of
++ matrices. The functions resemble operations often used in numerical
++ linear algebra algorithms.
```

```
MatrixManipulation(R, Row, Col, M) : SIG == CODE where
  R : Field
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M : MatrixCategory(R, Row, Col)
```

```
I ==> Integer
PI ==> PositiveInteger
LI ==> List I
SI ==> Segment I
LPI ==> List PI
SPI ==> Segment PI
```

```
SIG ==> with
```

```
-- Slicing matrices
```

```
-- How to call aRow, aColumn? Name clashed with usual row, column
```

```

-- Package call is ugly because of many parameters of MAMA

SIG ==> with

gcd : (U,U,I) -> U
++ gcd(f1,f2,p) computes the gcd of the univariate polynomials
++ f1 and f2 modulo the integer prime p.

linears : (U,I) -> U
++ linears(f,p) returns the product of all the linear factors
++ of f modulo p. Potentially incorrect result if f is not
++ square-free modulo p.

factor : (U,I) -> L U
++ factor(f1,p) returns the list of factors of the univariate
++ polynomial f1 modulo the integer prime p.
++ Error: if f1 is not square-free modulo p.

ddFact : (U,I) -> UDDLList
++ ddFact(f,p) computes a distinct degree factorization of the
++ polynomial f modulo the prime p, such that each factor
++ is a product of irreducibles of the same degrees. The input
++ polynomial f is assumed to be square-free modulo p.

separateFactors : (UDDLList,I) -> L U
++ separateFactors(ddl, p) refines the distinct degree factorization
++ produced by ddFact to give a complete list of factors.

exptMod : (U,I,U,I) -> U
++ exptMod(f,n,g,p) raises the univariate polynomial f to the nth
++ power modulo the polynomial g and the prime p.

++ Author: Manuel Bronstein
++ Date Created: 22 February 1989
++ Date Last Updated: 24 November 1993
++ Description:
++ Modular hermitian row reduction.
-- should be moved into matrix whenever possible

ModularHermitianRowReduction(R) : SIG == CODE where
  R : EuclideanDomain

  Z ==> Integer
  V ==> Vector R
  M ==> Matrix R
  REC ==> Record(val:R, cl:Z, rw:Z)

  SIG ==> with

    rowEch : M -> M
      ++ rowEch(m) computes a modular row-echelon form of m, finding
      ++ an appropriate modulus.

    rowEchelon : (M, R) -> M
      ++ rowEchelon(m, d) computes a modular row-echelon form mod d of
      ++ [d ]
      ++ [ d ]
      ++ [ . ]
      ++ [ d]
      ++ [ M ]
      ++ where \spad{M = m mod d}.

    rowEchLocal : (M, R) -> M
      ++ rowEchLocal(m,p) computes a modular row-echelon form of m, finding
      ++ an appropriate modulus over a local ring where p is the only prime.

    rowEchelonLocal : (M, R, R) -> M
      ++ rowEchelonLocal(m, d, p) computes the row-echelon form of m
      ++ concatenated with d times the identity matrix
      ++ over a local ring where p is the only prime.

    normalizedDivide : (R, R) -> Record(quotient:R, remainder:R)
      ++ normalizedDivide(n,d) returns a normalized quotient and
      ++ remainder such that consistently unique representatives
      ++ for the residue class are chosen, for example, positive remainders

  CODE ==> add

```

```

SIG ==> with

```

```

  gradient : (F,FLAS) -> Vector F
  ++ \spad{gradient(v,xlist)}
  ++ computes the gradient, the vector of first partial derivatives,
  ++ of the scalar field v,
  ++ v a function of the variables listed in xlist.

```

```

  divergence : (FLAF,FLAS) -> F
  ++ \spad{divergence(vf,xlist)}

```

```

++ computes the divergence of the vector field vf,
++ vf a vector function of the variables listed in xlist.

laplacian : (F,FLAS) -> F
++ \spad{laplacian(v,xlist)}
++ computes the laplacian of the scalar field v,
++ v a function of the variables listed in xlist.

hessian : (F,FLAS) -> Matrix F
++ \spad{hessian(v,xlist)}
++ computes the hessian, the matrix of second partial derivatives,
++ of the scalar field v,
++ v a function of the variables listed in xlist.

bandedHessian : (F,FLAS,NNI) -> Matrix F
++ \spad{bandedHessian(v,xlist,k)}
++ computes the hessian, the matrix of second partial derivatives,
++ of the scalar field v,
++ v a function of the variables listed in xlist,
++ k is the semi-bandwidth, the number of nonzero subdiagonals,
++ 2*k+1 being actual bandwidth.
++ Stores the nonzero band in lower triangle in a matrix,
++ dimensions k+1 by #xlist,
++ whose rows are the vectors formed by diagonal, subdiagonal, etc.
++ of the real, full-matrix, hessian.
++ (The notation conforms to LAPACK/NAG-F07 conventions.)

-- At one stage it seemed a good idea to help the ASP<n> domains
-- with the types of their input arguments and this led to the
-- standard Gradient|Hessian|Jacobian functions.
--standardJacobian: (Vector(F),List(S)) -> Matrix F
-- ++ \spad{jacobian(vf,xlist)}
-- ++ computes the jacobian, the matrix of first partial derivatives,
-- ++ of the vector field vf,
-- ++ vf a vector function of the variables listed in xlist.

jacobian : (FLAF,FLAS) -> Matrix F
++ \spad{jacobian(vf,xlist)}
++ computes the jacobian, the matrix of first partial derivatives,
++ of the vector field vf,
++ vf a vector function of the variables listed in xlist.

bandedJacobian : (FLAF,FLAS,NNI,NNI) -> Matrix F
++ \spad{bandedJacobian(vf,xlist,kl,ku)}
++ computes the jacobian, the matrix of first partial derivatives,
++ of the vector field vf,
++ vf a vector function of the variables listed in xlist,
++ kl is the number of nonzero subdiagonals,
++ ku is the number of nonzero superdiagonals,
++ kl+ku+1 being actual bandwidth.

```

```

++ Stores the nonzero band in a matrix,
++ dimensions kl+ku+1 by #xlist.
++ The upper triangle is in the top ku rows,
++ the diagonal is in row ku+1,
++ the lower triangle in the last kl rows.
++ Entries in a column in the band store correspond to entries
++ in same column of full store.
++ (The notation conforms to LAPACK/NAG-F07 conventions.)

)abbrev package MLIFT MultivariateLifting
++ Author : P.Gianni.
++ Description:
++ This package provides the functions for the multivariate "lifting", using
++ an algorithm of Paul Wang.
++ This package will work for every euclidean domain R which has property
++ F, there exists a factor operation in \spad{R[x]}.

— NagEigenPackage.help —

This package uses the NAG Library to compute

- * eigenvalues and eigenvectors of a matrix\
- * eigenvalues and eigenvectors of generalized matrix
- * eigenvalue problems
- * singular values and singular vectors of a matrix.

Chapter F02 Eigenvalues and Eigenvectors

1. Scope of the Chapter

This chapter is concerned with computing

- eigenvalues and eigenvectors of a matrix
- eigenvalues and eigenvectors of generalized matrix eigenvalue problems
- singular values and singular vectors of a matrix.

2. Background to the Problems

2.1. Eigenvalue Problems

In the most usual form of eigenvalue problem we are given a square n by n matrix A and wish to compute (λ) (an eigenvalue) and $x \neq 0$ (an eigenvector) which satisfy the equation

$$Ax = (\lambda)x$$

Such problems are called 'standard' eigenvalue problems in contrast to 'generalized' eigenvalue problems where we wish to satisfy the equation

$$Ax = (\lambda)Bx$$

B also being a square n by n matrix.

Section 2.1.1 and Section 2.1.2 discuss, respectively, standard and generalized eigenvalue problems where the matrices involved are dense; Section 2.1.3 discusses both types of problem in the case where A and B are sparse (and symmetric).

2.1.1. Standard eigenvalue problems

Some of the routines in this chapter find all the n eigenvalues, some find all the n eigensolutions (eigenvalues and corresponding eigenvectors), and some find a selected group of eigenvalues and/or eigenvectors. The matrix A may be:

- (i) general (real or complex)
- (ii) real symmetric, or
- (iii) complex Hermitian (so that if $a_{ij} = (\alpha) + i(\beta)$ then $a_{ji} = (\alpha) - i(\beta)$)

$$a_{ji} = (\alpha - i(\beta)) \delta_{ji}.$$

In all cases the computation starts with a similarity

transformation $S^{-1}AS = T$, where S is non-singular and is the product of fairly simple matrices, and T has an 'easier form' than A so that its eigensolutions are easily determined. The matrices A and T , of course, have the same eigenvalues, and if y is an eigenvector of T then Sy is the corresponding eigenvector of A .

In case (i) (general real or complex A), the selected form of T is an upper Hessenberg matrix ($t_{ij} = 0$ if $i - j > 1$) and S is the

product of $n-2$ stabilised elementary transformation matrices. There is no easy method of computing selected eigenvalues of a Hessenberg matrix, so that all eigenvalues are always calculated. In the real case this computation is performed via the Francis QR algorithm with double shifts, and in the complex case by means of the LR algorithm. If the eigenvectors are required they are computed by back-substitution following the QR and LR algorithm.

In case (ii) (real and symmetric A) the selected simple form of T is a tridiagonal matrix ($t_{ij} = 0$ if $|i - j| > 1$), and S is the product

of $n-2$ orthogonal Householder transformation matrices. If only selected eigenvalues are required, they are obtained by the method of bisection using the Sturm sequence property, and the corresponding eigenvectors of T are computed by inverse iteration. If all eigenvalues are required, they are computed from T via the QL algorithm (an adaptation of the QR algorithm), and the corresponding eigenvectors of T are the product of the transformations for the QL reduction. In all cases the corresponding eigenvectors of A are recovered from the computation of $x = Sy$.

In case (iii) (complex Hermitian A) analogous transformations as in case (ii) are used. T has complex elements in off-diagonal positions, but a simple diagonal similarity transformation is then used to produce a real tridiagonal form, after which the QL algorithm and succeeding methods described in the previous paragraph are used to complete the solution.

2.1.2. Generalized eigenvalue problems

Here we distinguish as a special case those problems in which both A and B are symmetric and B is positive-definite and well-conditioned with respect to inversion (all the eigenvalues of B are significantly greater than zero). Such problems can be

satisfactorily treated by first reducing them to case (ii) of Section 2.1.1 and then using the methods described there to

compute the eigensolutions. If B is factorized as LL^T (L lower triangular), then $Ax=(\lambda)Bx$ is equivalent to the standard symmetric problem $Ry=(\lambda)y$, where $R=L^{-1}A(L^{-1})^T$ and $y=L^T x$. After finding an eigenvector y of R , the required x is computed by back-substitution in $y=L^T x$.

For generalized problems of the form $Ax=(\lambda)Bx$ which do not fall into the special case, the QZ algorithm is provided.

In order to appreciate the domain in which this algorithm is appropriate we remark first that when B is non-singular the problem $Ax=(\lambda)Bx$ is fully equivalent to the problem

$(B^{-1}A)x=(\lambda)x$; both the eigenvalues and eigenvectors being the same. When A is non-singular $Ax=(\lambda)Bx$ is equivalent to the problem

$(A^{-1}B)x=(\mu)x$; the eigenvalues (μ) being the reciprocals of the required eigenvalues and the eigenvectors remaining the same. In theory then, provided at least one of the matrices A and B is non-singular, the generalized problem $Ax=(\lambda)Bx$ could be solved via the standard problem $Cx=(\lambda)x$ with an appropriate matrix C , and as far as economy of effort is concerned this is quite satisfactory. However, in practice, for this reduction to be satisfactory from the standpoint of numerical stability, one requires more than the

mere non-singularity of A or B . It is necessary that $B^{-1}A$ (or $A^{-1}B$) should not only exist but that $B^{-1}A$ (or $A^{-1}B$) should be well-conditioned with respect to inversion. The nearer $B^{-1}A$ (or $A^{-1}B$) is to

singularity the more unsatisfactory $B^{-1}A$ (or $A^{-1}B$) will be as a vehicle for determining the required eigenvalues. Unfortunately one cannot counter ill-conditioning in $B^{-1}A$ (or $A^{-1}B$) by computing $B^{-1}A$

(or $A^{-1}B$) accurately to single precision using iterative refinement. Well-determined eigenvalues of the original $Ax=(\lambda)Bx$ may be poorly determined even by the correctly

rounded version of $B^{-1}A$ (or $A^{-1}B$). The situation may in some instances be saved by the observation that if $Ax=(\lambda)Bx$ then $(A-kB)x=((\lambda)-k)Bx$. Hence if $A-kB$ is non-singular we may

solve the standard problem $[(A-kB)^{-1}B]x=(\mu)x$ and for numerical

stability we require only that $(A-kB)$ be well-conditioned with respect to inversion.

In practice one may well be in a situation where no k is known for which $(A-kB)$ is well-conditioned with respect to inversion and indeed $(A-kB)$ may be singular for all k . The QZ algorithm is designed to deal directly with the problem $Ax=(\lambda)Bx$ itself and its performance is unaffected by singularity or near-singularity of A , B or $A-kB$.

2.1.3. Sparse symmetric problems

If the matrices A and B are large and sparse (only a small proportion of the elements are non-zero), then the methods described in the previous Section are unsuitable, because in reducing the problem to a simpler form, much of the sparsity of the problem would be lost; hence the computing time and the storage required would be very large. Instead, for symmetric problems, the method of simultaneous iteration may be used to determine selected eigenvalues and the corresponding eigenvectors. The routine provided has been designed to handle both symmetric and generalized symmetric problems.

2.2. Singular Value Problems

The singular value decomposition of an m by n real matrix A is given by

$$A = QDP^T,$$

where Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and D is an m by n diagonal matrix with non-negative diagonal elements. The first $k=\min(m,n)$ columns of Q and P are the left- and right-hand singular vectors of A and the k diagonal elements of D are the singular values.

When A is complex then the singular value decomposition is given by

$$A = QDP^H,$$

where Q and P are unitary, P^H denotes the complex conjugate of P^T and D is as above for the real case.

If the matrix A has column means of zero, then AP is the matrix of principal components of A and the singular values are the square roots of the sample variances of the observations with

respect to the principal components. (See also Chapter G03.)

Routines are provided to return the singular values and vectors of a general real or complex matrix.

3. Recommendations on Choice and Use of Routines

3.1. General Discussion

There is one routine, F02FJF, which is designed for sparse symmetric eigenvalue problems, either standard or generalized. The remainder of the routines are designed for dense matrices.

3.2. Eigenvalue and Eigenvector Routines

These reduce the matrix A to a simpler form by a similarity

$S^{-1}AS = T$ where T is an upper Hessenberg or tridiagonal matrix, compute the eigensolutions of T , and then recover the eigenvectors of A via the matrix S . The eigenvectors are normalised so that

$$\sum_{r=1}^n |x_r|^2 = 1$$

x_r being the r th component of the eigenvector x , and so that the element of largest modulus is real if x is complex. For problems of the type $Ax = (\lambda B)x$ with A and B symmetric and B positive-definite, the eigenvectors are normalised so that $x^T B x = 1$, x always being real for such problems.

3.3. Singular Value and Singular Vector Routines

These reduce the matrix A to real bidiagonal form, B say, by orthogonal transformations $Q^T A P = B$ in the real case, and by

unitary transformations $Q^H A P = B$ in the complex case, and the singular values and vectors are computed via this bidiagonal form. The singular values are returned in descending order.

3.4. Decision Trees

- (i) Eigenvalues and Eigenvectors

F02 -- Eigenvalue and Eigenvectors F02AAF
 F02AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AAF calculates all the eigenvalues of a real symmetric matrix.

2. Specification

```
SUBROUTINE F02AAF (A, IA, N, R, E, IFAIL)
  INTEGER          IA, N, IFAIL
  DOUBLE PRECISION A(IA,N), R(N), E(N)
```

3. Description

This routine reduces the real symmetric matrix A to a real symmetric tridiagonal matrix using Householder's method. The eigenvalues of the tridiagonal matrix are then determined using the QL algorithm.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- | | | |
|----|---|--------------|
| 1: | A(IA,N) -- DOUBLE PRECISION array | Input/Output |
| | On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged. | |
| 2: | IA -- INTEGER | Input |
| | On entry:
the first dimension of the array A as declared in the (sub)program from which F02AAF is called.
Constraint: IA >= N. | |
| 3: | N -- INTEGER | Input |
| | On entry: n, the order of the matrix A. | |
| 4: | R(N) -- DOUBLE PRECISION array | Output |

On exit: the eigenvalues in ascending order.

5: E(N) -- DOUBLE PRECISION array Workspace

6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 Failure in F02AVF(*) indicating that more than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the eigenvalues depends on the sensitivity of the matrix to rounding errors produced in tridiagonalisation. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the real symmetric matrix:

```
( 0.5  0.0  2.3 -2.6)
( 0.0  0.5 -1.4 -0.7)
( 2.3 -1.4  0.5  0.0).
(-2.6 -0.7  0.0  0.5)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

F02 -- Eigenvalue and Eigenvectors F02ABF
 F02ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02ABF calculates all the eigenvalues and eigenvectors of a real symmetric matrix.

2. Specification

```
SUBROUTINE F02ABF (A, IA, N, R, V, IV, E, IFAIL)
  INTEGER          IA, N, IV, IFAIL
  DOUBLE PRECISION A(IA,N), R(N), V(IV,N), E(N)
```

3. Description

This routine reduces the real symmetric matrix A to a real symmetric tridiagonal matrix by Householder's method. The eigenvalues and eigenvectors are calculated using the QL algorithm.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input
On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. See also Section 8.
- 2: IA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02ABF is called.
Constraint: IA >= N.
- 3: N -- INTEGER Input
On entry: n, the order of the matrix A.
- 4: R(N) -- DOUBLE PRECISION array Output
On exit: the eigenvalues in ascending order.
- 5: V(IV,N) -- DOUBLE PRECISION array Output
On exit: the normalised eigenvectors, stored by columns;
the ith column corresponds to the ith eigenvalue. The

eigenvectors are normalised so that the sum of squares of the elements is equal to 1.

- 6: IV -- INTEGER Input
 On entry:
 the first dimension of the array V as declared in the
 (sub)program from which F02ABF is called.
 Constraint: IV $\geq$ N.
- 7: E(N) -- DOUBLE PRECISION array Workspace
- 8: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 Failure in F02AMF(*) indicating that more than 30*N
 iterations are required to isolate all the eigenvalues.

7. Accuracy

The eigenvectors are always accurately orthogonal but the accuracy of the individual eigenvectors is dependent on their inherent sensitivity to changes in the original matrix. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and V, in which case the eigenvectors will overwrite the original matrix. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the real symmetric matrix:

```

( 0.5  0.0  2.3 -2.6)
( 0.0  0.5 -1.4 -0.7)
( 2.3 -1.4  0.5  0.0).
(-2.6 -0.7  0.0  0.5)

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

```

F02 -- Eigenvalue and Eigenvectors                                F02ADF
      F02ADF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02ADF calculates all the eigenvalues of $Ax=(\lambda)Bx$, where A is a real symmetric matrix and B is a real symmetric positive-definite matrix.

2. Specification

```

SUBROUTINE F02ADF (A, IA, B, IB, N, R, DE, IFAIL)
  INTEGER          IA, IB, N, IFAIL
  DOUBLE PRECISION A(IA,N), B(IB,N), R(N), DE(N)

```

3. Description

The problem is reduced to the standard symmetric eigenproblem using Cholesky's method to decompose B into triangular matrices,

$$B = LL^T, \text{ where } L \text{ is lower triangular. Then } Ax=(\lambda)Bx \text{ implies}$$

$$L^{-1} L^T L x = (\lambda) L^T L x; \text{ hence the eigenvalues of}$$

$$Ax=(\lambda)Bx \text{ are those of } Py=(\lambda)y \text{ where } P \text{ is the symmetric}$$

$$L^{-1} L^T$$

matrix $L^{-1} L^T$. Householder's method is used to tridiagonalise the matrix P and the eigenvalues are then found using the QL algorithm.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged.

- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02ADF is called.
 Constraint: IA $\geq$ N.

- 3: B(IB,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric positive-definite matrix B. The elements of the array below the diagonal need not be set. On exit: the elements below the diagonal are overwritten. The rest of the array is unchanged.

- 4: IB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the (sub)program from which F02ADF is called.
 Constraint: IB $\geq$ N.

- 5: N -- INTEGER Input
 On entry: n, the order of the matrices A and B.

- 6: R(N) -- DOUBLE PRECISION array Output
 On exit: the eigenvalues in ascending order.

- 7: DE(N) -- DOUBLE PRECISION array Workspace

- 8: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

Failure in F01AEF(*); the matrix B is not positive-definite

possibly due to rounding errors.

IFAIL= 2

Failure in F02AVF(*), more than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-conditioned with respect to inversion, the eigenvalues could be inaccurately determined. For a detailed error analysis see Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the general symmetric eigenproblem $Ax=(\lambda) Bx$ where A is the symmetric matrix:

```
(0.5  1.5  6.6  4.8)
(1.5  6.5 16.2  8.6)
(6.6 16.2 37.6  9.8)
(4.8  8.6  9.8 -17.1)
```

and B is the symmetric positive-definite matrix:

```
(1  3  4  1)
(3 13 16 11)
(4 16 24 18).
(1 11 18 27)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AEF
 F02AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AEF calculates all the eigenvalues and eigenvectors of $Ax=(\lambda)Bx$, where A is a real symmetric matrix and B is a real symmetric positive-definite matrix.

2. Specification

```

      SUBROUTINE F02AEF (A, IA, B, IB, N, R, V, IV, DL, E, IFAIL)
      INTEGER          IA, IB, N, IV, IFAIL
      DOUBLE PRECISION A(IA,N), B(IB,N), R(N), V(IV,N), DL(N), E
1              (N)

```

3. Description

The problem is reduced to the standard symmetric eigenproblem using Cholesky's method to decompose B into triangular matrices

$B=LL^T$, where L is lower triangular. Then $Ax=(\lambda)Bx$ implies $(L^{-1}AL^{-T})(Lx)=(\lambda)(Lx)$; hence the eigenvalues of $Ax=(\lambda)Bx$ are those of $Py=(\lambda)y$, where P is the symmetric

matrix $L^{-1}AL^{-T}$. Householder's method is used to tridiagonalise the matrix P and the eigenvalues are found using the QL algorithm. An eigenvector z of the derived problem is related to

an eigenvector x of the original problem by $z=L^{-T}x$. The eigenvectors z are determined using the QL algorithm and are

normalised so that $z^T z=1$; the eigenvectors of the original

problem are then determined by solving $L^{-1}x=z$, and are normalised so that $x^T Bx=1$.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

1: A(IA,N) -- DOUBLE PRECISION array Input/Output

On entry: the upper triangle of the n by n symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged. See also Section 8.

- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the
 (sub)program from which F02AEF is called.
 Constraint: IA $\geq$ N.
- 3: B(IB,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric
 positive-definite matrix B. The elements of the array below
 the diagonal need not be set. On exit: the elements below
 the diagonal are overwritten. The rest of the array is
 unchanged.
- 4: IB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the
 (sub)program from which F02AEF is called.
 Constraint: IB $\geq$ N.
- 5: N -- INTEGER Input
 On entry: n, the order of the matrices A and B.
- 6: R(N) -- DOUBLE PRECISION array Output
 On exit: the eigenvalues in ascending order.
- 7: V(IV,N) -- DOUBLE PRECISION array Output
 On exit: the normalised eigenvectors, stored by columns;
 the ith column corresponds to the ith eigenvalue. The
 $\begin{matrix} T \\ \text{eigenvectors } x \text{ are normalised so that } x^T B x = 1. \text{ See also} \\ \text{Section 8.} \end{matrix}$
- 8: IV -- INTEGER Input
 On entry:
 the first dimension of the array V as declared in the
 (sub)program from which F02AEF is called.
 Constraint: IV $\geq$ N.
- 9: DL(N) -- DOUBLE PRECISION array Workspace
- 10: E(N) -- DOUBLE PRECISION array Workspace
- 11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

Failure in F01AEF(*); the matrix B is not positive-definite, possibly due to rounding errors.

IFAIL= 2

Failure in F02AMF(*); more than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-conditioned with respect to inversion, the eigenvectors could be inaccurately determined. For a detailed error analysis see Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n^3

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and V, in which case the eigenvectors will overwrite the original matrix A. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the general symmetric eigenproblem $Ax = (\lambda B)x$ where A is the symmetric matrix:

```
(0.5  1.5  6.6  4.8)
(1.5  6.5 16.2  8.6)
(6.6 16.2 37.6  9.8)
(4.8  8.6  9.8 -17.1)
```

and B is the symmetric positive-definite matrix:

```
(1  3  4  1)
(3 13 16 11)
(4 16 24 18)
(1 11 18 27)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AFF
 F02AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AFF calculates all the eigenvalues of a real unsymmetric matrix.

2. Specification

```
SUBROUTINE F02AFF (A, IA, N, RR, RI, INTGER, IFAIL)
  INTEGER          IA, N, INTGER(N), IFAIL
  DOUBLE PRECISION A(IA,N), RR(N), RI(N)
```

3. Description

The matrix A is first balanced and then reduced to upper Hessenberg form using stabilised elementary similarity transformations. The eigenvalues are then found using the QR algorithm for real Hessenberg matrices.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- | | | |
|----|--|--------------|
| 1: | A(IA,N) -- DOUBLE PRECISION array | Input/Output |
| | On entry: the n by n matrix A. On exit: the array is overwritten. | |
| 2: | IA -- INTEGER | Input |
| | On entry:
the dimension of the array A as declared in the (sub)program from which F02AFF is called.
Constraint: IA >= N. | |
| 3: | N -- INTEGER | Input |
| | On entry: n, the order of the matrix A. | |
| 4: | RR(N) -- DOUBLE PRECISION array | Output |

On exit: the real parts of the eigenvalues.

5: RI(N) -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvalues.

6: INTGER(N) -- INTEGER array Output
 On exit: INTGER(i) contains the number of iterations used to find the ith eigenvalue. If INTGER(i) is negative, the ith eigenvalue is the second of a pair found simultaneously.

Note that the eigenvalues are found in reverse order, starting with the nth.

7: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 More than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 367.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the real matrix:

```
( 1.5 0.1  4.5 -1.5)
(-22.5 3.5 12.5 -2.5)
( -2.5 0.3  4.5 -2.5).
( -2.5 0.1  4.5  2.5)
```

The example program is not reproduced here. The source code for

all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AGF
 F02AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AGF calculates all the eigenvalues and eigenvectors of a real unsymmetric matrix.

2. Specification

```

      SUBROUTINE F02AGF (A, IA, N, RR, RI, VR, IVR, VI, IVI,
1      INTEGER, IFAIL)
      INTEGER      IA, N, IVR, IVI, INTGER(N), IFAIL
      DOUBLE PRECISION A(IA,N), RR(N), RI(N), VR(IVR,N), VI
1      (IVI,N)

```

3. Description

The matrix A is first balanced and then reduced to upper Hessenberg form using real stabilised elementary similarity transformations. The eigenvalues and eigenvectors of the Hessenberg matrix are calculated using the QR algorithm. The eigenvectors of the Hessenberg matrix are back-transformed to give the eigenvectors of the original matrix A.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the n by n matrix A. On exit: the array is overwritten.
- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02AGF is called.

Constraint: $IA \geq N$.

- 3: N -- INTEGER Input
On entry: n, the order of the matrix A.

- 4: RR(N) -- DOUBLE PRECISION array Output
On exit: the real parts of the eigenvalues.

- 5: RI(N) -- DOUBLE PRECISION array Output
On exit: the imaginary parts of the eigenvalues.

- 6: VR(IVR,N) -- DOUBLE PRECISION array Output
On exit: the real parts of the eigenvectors, stored by columns. The ith column corresponds to the ith eigenvalue. The eigenvectors are normalised so that the sum of the squares of the moduli of the elements is equal to 1 and the element of largest modulus is real. This ensures that real eigenvalues have real eigenvectors.

- 7: IVR -- INTEGER Input
On entry:
the first dimension of the array VR as declared in the (sub)program from which F02AGF is called.
Constraint: $IVR \geq N$.

- 8: VI(IVI,N) -- DOUBLE PRECISION array Output
On exit: the imaginary parts of the eigenvectors, stored by columns. The ith column corresponds to the ith eigenvalue.

- 9: IVI -- INTEGER Input
On entry:
the first dimension of the array VI as declared in the (sub)program from which F02AGF is called.
Constraint: $IVI \geq N$.

- 10: INTGER(N) -- INTEGER array Output
On exit: INTGER(i) contains the number of iterations used to find the ith eigenvalue. If INTGER(i) is negative, the ith eigenvalue is the second of a pair found simultaneously.

Note that the eigenvalues are found in reverse order, starting with the nth.

- 11: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

More than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 390.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues and eigenvectors of the real matrix:

```
( 1.5 0.1  4.5 -1.5)
(-22.5 3.5 12.5 -2.5)
( -2.5 0.3  4.5 -2.5).
( -2.5 0.1  4.5  2.5)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AJF
F02AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AJF calculates all the eigenvalues of a complex matrix.

2. Specification

```

SUBROUTINE F02AJF (AR, IAR, AI, IAI, N, RR, RI, INTGER,
1                IFAIL)
  INTEGER          IAR, IAI, N, INTGER(N), IFAIL
  DOUBLE PRECISION AR(IAR,N), AI(IAI,N), RR(N), RI(N)

```

3. Description

The complex matrix A is first balanced and then reduced to upper Hessenberg form using stabilised elementary similarity transformations. The eigenvalues are then found using the modified LR algorithm for complex Hessenberg matrices.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input/Output
On entry: the real parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.
- 2: IAR -- INTEGER Input
On entry:
the first dimension of the array AR as declared in the (sub)program from which F02AJF is called.
Constraint: IAR >= N.
- 3: AI(IAI,N) -- DOUBLE PRECISION array Input/Output
On entry: the imaginary parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.
- 4: IAI -- INTEGER Input
On entry:
the first dimension of the array AI as declared in the (sub)program from which F02AJF is called.
Constraint: IAI >= N.
- 5: N -- INTEGER Input
On entry: n, the order of the matrix A.
- 6: RR(N) -- DOUBLE PRECISION array Output
On exit: the real parts of the eigenvalues.
- 7: RI(N) -- DOUBLE PRECISION array Output
On exit: the imaginary parts of the eigenvalues.
- 8: INTGER(N) -- INTEGER array Workspace

9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 More than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 401.

8. Further Comments

3

The time taken by the routine is approximately proportional to n^3

9. Example

To calculate all the eigenvalues of the complex matrix:

```
(-21.0-5.0i      24.60i 13.6+10.2i      4.0i)
(      22.5i 26.00-5.00i  7.5-10.0i 2.5      )
( -2.0+1.5i  1.68+2.24i  4.5-5.0i  1.5+2.0i).
(      -2.5i -2.60      -2.7+3.6i  2.5-5.0i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AKF
 F02AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AKF calculates all the eigenvalues and eigenvectors of a complex matrix.

2. Specification

```

      SUBROUTINE F02AKF (AR, IAR, AI, IAI, N, RR, RI, VR, IVR,
1          VI, IVI, INTGER, IFAIL)
      INTEGER          IAR, IAI, N, IVR, IVI, INTGER(N), IFAIL
      DOUBLE PRECISION AR(IAR,N), AI(IAI,N), RR(N), RI(N), VR
1          (IVR,N), VI(IVI,N)

```

3. Description

The complex matrix A is first balanced and then reduced to upper Hessenberg form by stabilised elementary similarity transformations. The eigenvalues and eigenvectors of the Hessenberg matrix are calculated using the LR algorithm. The eigenvectors of the Hessenberg matrix are back-transformed to give the eigenvectors of the original matrix.

4. References

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input/Output
On entry: the real parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.
- 2: IAR -- INTEGER Input
On entry:
the first dimension of the array AR as declared in the (sub)program from which F02AKF is called.
Constraint: IAR >= N.
- 3: AI(IAI,N) -- DOUBLE PRECISION array Input/Output
On entry: the imaginary parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.
- 4: IAI -- INTEGER Input
On entry:
the first dimension of the array AI as declared in the (sub)program from which F02AKF is called.
Constraint: IAI >= N.
- 5: N -- INTEGER Input

On entry: n , the order of the matrix A .

- 6: $RR(N)$ -- DOUBLE PRECISION array Output
 On exit: the real parts of the eigenvalues.
- 7: $RI(N)$ -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvalues.
- 8: $VR(IVR,N)$ -- DOUBLE PRECISION array Output
 On exit: the real parts of the eigenvectors, stored by columns. The i th column corresponds to the i th eigenvalue. The eigenvectors are normalised so that the sum of squares of the moduli of the elements is equal to 1 and the element of largest modulus is real.
- 9: IVR -- INTEGER Input
 On entry:
 the first dimension of the array VR as declared in the (sub)program from which F02AKF is called.
 Constraint: $IVR \geq N$.
- 10: $VI(IVI,N)$ -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvectors, stored by columns. The i th column corresponds to the i th eigenvalue.
- 11: IVI -- INTEGER Input
 On entry:
 the first dimension of the array VI as declared in the (sub)program from which F02AKF is called.
 Constraint: $IVI \geq N$.
- 12: $INTGER(N)$ -- INTEGER array Workspace
- 13: $IFAIL$ -- INTEGER Input/Output
 On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

$IFAIL = 1$

More than $30 \times N$ iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the results depends on the conditioning of the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 390.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues and eigenvectors of the complex matrix:

```
(-21.0-5.0i      24.60i 13.6+10.2i      4.0i)
(      22.5i 26.00-5.00i  7.5-10.0i 2.5      )
( -2.0+1.5i  1.68+2.24i  4.5-5.0i  1.5+2.0i).
(      -2.5i -2.60      -2.7+3.6i  2.5-5.0i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```
F02 -- Eigenvalue and Eigenvectors                                F02AWF
      F02AWF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AWF calculates all the eigenvalues of a complex Hermitian matrix.

2. Specification

```
SUBROUTINE F02AWF (AR, IAR, AI, IAI, N, R, WK1, WK2, WK3,
1                  IFAIL)
      INTEGER      IAR, IAI, N, IFAIL
      DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), WK1(N),
1                  WK2(N), WK3(N)
```

3. Description

The complex Hermitian matrix A is first reduced to a real

tridiagonal matrix by $n-2$ unitary transformations, and a subsequent diagonal transformation. The eigenvalues are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

- [1] Peters G (1967) NPL Algorithms Library. Document No. F1/04/A.
- [2] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input/Output
On entry: the real parts of the elements of the lower triangle of the n by n complex Hermitian matrix A . Elements of the array above the diagonal need not be set. On exit: the array is overwritten.
- 2: IAR -- INTEGER Input
On entry:
the first dimension of the array AR as declared in the (sub)program from which F02AWF is called.
Constraint: IAR $\geq$ N.
- 3: AI(IAI,N) -- DOUBLE PRECISION array Input/Output
On entry: the imaginary parts of the elements of the lower triangle of the n by n complex Hermitian matrix A . Elements of the array above the diagonal need not be set. On exit: the array is overwritten.
- 4: IAI -- INTEGER Input
On entry:
the first dimension of the array AI as declared in the (sub)program from which F02AWF is called.
Constraint: IAI $\geq$ N.
- 5: N -- INTEGER Input
On entry: n , the order of the complex Hermitian matrix, A .
- 6: R(N) -- DOUBLE PRECISION array Output
On exit: the eigenvalues in ascending order.
- 7: WK1(N) -- DOUBLE PRECISION array Workspace
- 8: WK2(N) -- DOUBLE PRECISION array Workspace
- 9: WK3(N) -- DOUBLE PRECISION array Workspace

10: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 More than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

For a detailed error analysis see Peters [1] page 3 and Wilkinson and Reinsch [2] page 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the complex Hermitian matrix:

(0.50	0.00	1.84+1.38i	2.08-1.56i)
(0.00	0.50	1.12+0.84i	-0.56+0.42i)
(1.84-1.38i	1.12-0.84i	0.50	0.00)
(2.08+1.56i	-0.56-0.42i	0.00	0.50)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AXF
 F02AXF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AXF calculates all the eigenvalues and eigenvectors of a complex Hermitian matrix.

2. Specification

```

      SUBROUTINE F02AXF (AR, IAR, AI, IAI, N, R, VR, IVR, VI,
1      IVI, WK1, WK2, WK3, IFAIL)
      INTEGER          IAR, IAI, N, IVR, IVI, IFAIL
      DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), VR(IVR,N), VI
1      (IVI,N), WK1(N), WK2(N), WK3(N)

```

3. Description

The complex Hermitian matrix is first reduced to a real tridiagonal matrix by $n-2$ unitary transformations and a subsequent diagonal transformation. The eigenvalues and eigenvectors are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

- [1] Peters G (1967) NPL Algorithms Library. Document No. F2/03/A.
- [2] Peters G (1967) NPL Algorithms Library. Document No. F1/04/A.

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input
 On entry: the real parts of the elements of the lower triangle of the n by n complex Hermitian matrix A . Elements of the array above the diagonal need not be set. See also Section 8.
- 2: IAR -- INTEGER Input
 On entry:
 the first dimension of the array AR as declared in the (sub)program from which F02AXF is called.
 Constraint: IAR $\geq$ N.
- 3: AI(IAI,N) -- DOUBLE PRECISION array Input
 On entry: the imaginary parts of the elements of the lower triangle of the n by n complex Hermitian matrix A . Elements of the array above the diagonal need not be set. See also Section 8.
- 4: IAI -- INTEGER Input

On entry:
 the first dimension of the array AI as declared in the
 (sub)program from which F02AXF is called.
 Constraint: IAI $\geq$ N.

- 5: N -- INTEGER Input
 On entry: n, the order of the matrix, A.
- 6: R(N) -- DOUBLE PRECISION array Output
 On exit: the eigenvalues in ascending order.
- 7: VR(IVR,N) -- DOUBLE PRECISION array Output
 On exit: the real parts of the eigenvectors, stored by
 columns. The ith column corresponds to the ith eigenvector.
 The eigenvectors are normalised so that the sum of the
 squares of the moduli of the elements is equal to 1 and the
 element of largest modulus is real. See also Section 8.
- 8: IVR -- INTEGER Input
 On entry:
 the first dimension of the array VR as declared in the
 (sub)program from which F02AXF is called.
 Constraint: IVR $\geq$ N.
- 9: VI(IVI,N) -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvectors, stored by
 columns. The ith column corresponds to the ith eigenvector.
 See also Section 8.
- 10: IVI -- INTEGER Input
 On entry:
 the first dimension of the array VI as declared in the
 (sub)program from which F02AXF is called.
 Constraint: IVI $\geq$ N.
- 11: WK1(N) -- DOUBLE PRECISION array Workspace
- 12: WK2(N) -- DOUBLE PRECISION array Workspace
- 13: WK3(N) -- DOUBLE PRECISION array Workspace
- 14: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

More than 30*N iterations are required to isolate all the eigenvalues.

IFAIL= 2

The diagonal elements of AI are not all zero, the complex matrix is not Hermitian.

7. Accuracy

The eigenvectors are always accurately orthogonal but the accuracy of the individual eigenvalues and eigenvectors is dependent on their inherent sensitivity to small changes in the original matrix. For a detailed error analysis see Peters [1] page 3 and [2] page 3.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the implementation document, the routine may be called with the same actual array supplied for parameters AR and VR, and for AI and VI, in which case the eigenvectors will overwrite the original matrix A. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate the eigenvalues and eigenvectors of the complex Hermitian matrix:

(0.50	0.00	1.84+1.38i	2.08-1.56i)
(0.00	0.50	1.12+0.84i	-0.56+0.42i)
(1.84-1.38i	1.12-0.84i	0.50	0.00)
(2.08+1.56i	-0.56-0.42i	0.00	0.50)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors	F02BBF
F02BBF -- NAG Foundation Library Routine Document	

Note: Before using this routine, please read the Users' Note for

your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02BBF calculates selected eigenvalues and eigenvectors of a real symmetric matrix by reduction to tridiagonal form, bisection and inverse iteration, where the selected eigenvalues lie within a given interval.

2. Specification

```

      SUBROUTINE F02BBF (A, IA, N, ALB, UB, M, MM, R, V, IV, D,
1      E, E2, X, G, C, ICOUNT, IFAIL)
      INTEGER          IA, N, M, MM, IV, ICOUNT(M), IFAIL
      DOUBLE PRECISION A(IA,N), ALB, UB, R(M), V(IV,M), D(N), E
1      (N), E2(N), X(N,7), G(N)
      LOGICAL          C(N)

```

3. Description

The real symmetric matrix A is reduced to a symmetric tridiagonal matrix T by Householder's method. The eigenvalues which lie within a given interval [l,u], are calculated by the method of bisection. The corresponding eigenvectors of T are calculated by inverse iteration. A back-transformation is then performed to obtain the eigenvectors of the original matrix A.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged.
- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02BBF is called.
 Constraint: IA >= N.
- 3: N -- INTEGER Input
 On entry: n, the order of the matrix A.

- 4: ALB -- DOUBLE PRECISION Input
 5: UB -- DOUBLE PRECISION Input
 On entry: l and u, the lower and upper end-points of the interval within which eigenvalues are to be calculated.
 6: M -- INTEGER Input
 On entry: an upper bound for the number of eigenvalues within the interval.
 7: MM -- INTEGER Output
 On exit: the actual number of eigenvalues within the interval.
 8: R(M) -- DOUBLE PRECISION array Output
 On exit: the eigenvalues, not necessarily in ascending order.
 9: V(IV,M) -- DOUBLE PRECISION array Output
 On exit: the eigenvectors, stored by columns. The ith column corresponds to the ith eigenvalue. The eigenvectors are normalised so that the sum of the squares of the elements are equal to 1.
 10: IV -- INTEGER Input
 On entry:
 the first dimension of the array V as declared in the (sub)program from which F02BBF is called.
 Constraint: IV >= N.
 11: D(N) -- DOUBLE PRECISION array Workspace
 12: E(N) -- DOUBLE PRECISION array Workspace
 13: E2(N) -- DOUBLE PRECISION array Workspace
 14: X(N,7) -- DOUBLE PRECISION array Workspace
 15: G(N) -- DOUBLE PRECISION array Workspace
 16: C(N) -- LOGICAL array Workspace
 17: ICOUNT(M) -- INTEGER array Output
 On exit: ICOUNT(i) contains the number of iterations for the ith eigenvalue.
 18: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

Errors detected by the routine:

```
IFAIL= 2
    More than 5 iterations are required to determine any one
    eigenvector.
```

There is no guarantee of the accuracy of the eigenvectors as the results depend on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 436.

3
The time taken by the routine is approximately proportional to n^3

This subroutine should only be used when less than 25% of the eigenvalues and the corresponding eigenvectors are required. Also this subroutine is less efficient with matrices which have multiple eigenvalues.

To calculate the eigenvalues lying between -2.0 and 3.0, and the corresponding eigenvectors of the real symmetric matrix:

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

[illegible]

F02 -- Eigenvalue and Eigenvectors F02BJF
 F02BJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02BJF calculates all the eigenvalues and, if required, all the eigenvectors of the generalized eigenproblem $Ax=(\lambda)Bx$ where A and B are real, square matrices, using the QZ algorithm.

2. Specification

```

      SUBROUTINE F02BJF (N, A, IA, B, IB, EPS1, ALFR, ALFI,
1      BETA, MATV, V, IV, ITER, IFAIL)
      INTEGER          N, IA, IB, IV, ITER(N), IFAIL
      DOUBLE PRECISION A(IA,N), B(IB,N), EPS1, ALFR(N), ALFI(N),
1      BETA(N), V(IV,N)
      LOGICAL          MATV

```

3. Description

All the eigenvalues and, if required, all the eigenvectors of the generalized eigenproblem $Ax=(\lambda)Bx$ where A and B are real, square matrices, are determined using the QZ algorithm. The QZ algorithm consists of 4 stages:

- (a) A is reduced to upper Hessenberg form and at the same time B is reduced to upper triangular form.
- (b) A is further reduced to quasi-triangular form while the triangular form of B is maintained.
- (c) The quasi-triangular form of A is reduced to triangular form and the eigenvalues extracted. This routine does not actually produce the eigenvalues $(\lambda)_j$, but instead returns $(\alpha)_j$ and $(\beta)_j$ such that

$$(\lambda)_j = (\alpha)_j / (\beta)_j, \quad j=1,2,\dots,n$$

The division by $(\beta)_j$ becomes the responsibility of the user's program, since $(\beta)_j$ may be zero indicating an

infinite eigenvalue. Pairs of complex eigenvalues occur with $(\alpha)_j / (\beta)_j$ and $(\alpha)_{j+1} / (\beta)_{j+1}$ complex conjugates, even though $(\alpha)_j$ and $(\alpha)_{j+1}$ are not conjugate.

- (d) If the eigenvectors are required (MATV = .TRUE.), they are obtained from the triangular matrices and then transformed back into the original co-ordinate system.

- [3] Wilkinson J H (1979) Kronecker's Canonical Form and the QZ Algorithm. Linear Algebra and Appl. 28 285--303.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the order of the matrices A and B.
- 2: A(IA,N) -- DOUBLE PRECISION array Input/Output
On entry: the n by n matrix A. On exit: the array is overwritten.
- 3: IA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F02BJF is called.
Constraint: IA >= N.
- 4: B(IB,N) -- DOUBLE PRECISION array Input/Output
On entry: the n by n matrix B. On exit: the array is overwritten.
- 5: IB -- INTEGER Input
On entry:
the first dimension of the array B as declared in the (sub)program from which F02BJF is called.
Constraint: IB >= N.
- 6: EPS1 -- DOUBLE PRECISION Input

On entry: the tolerance used to determine negligible elements. If EPS1 > 0.0, an element will be considered negligible if it is less than EPS1 times the norm of its matrix. If EPS1 <= 0.0, machine precision is used in place of EPS1. A positive value of EPS1 may result in faster execution but less accurate results.

- 7: ALFR(N) -- DOUBLE PRECISION array Output
- 8: ALFI(N) -- DOUBLE PRECISION array Output
 On exit: the real and imaginary parts of (alpha) , for
j
 j=1,2,...,n.
- 9: BETA(N) -- DOUBLE PRECISION array Output
 On exit: (beta) , for j=1,2,...,n.
j
- 10: MATV -- LOGICAL Input
 On entry: MATV must be set .TRUE. if the eigenvectors are required, otherwise .FALSE..
- 11: V(IV,N) -- DOUBLE PRECISION array Output
 On exit: if MATV = .TRUE., then
 (i) if the jth eigenvalue is real, the jth column of V contains its eigenvector;

 (ii) if the jth and (j+1)th eigenvalues form a complex pair, the jth and (j+1)th columns of V contain the real and imaginary parts of the eigenvector associated with the first eigenvalue of the pair. The conjugate of this vector is the eigenvector for the conjugate eigenvalue.
 Each eigenvector is normalised so that the component of largest modulus is real and the sum of squares of the moduli equal one.

 If MATV = .FALSE., V is not used.
- 12: IV -- INTEGER Input
 On entry:
 the first dimension of the array V as declared in the (sub)program from which F02BJF is called.
 Constraint: IV >= N.
- 13: ITER(N) -- INTEGER array Output
 On exit: ITER(j) contains the number of iterations needed to obtain the jth eigenvalue. Note that the eigenvalues are obtained in reverse order, starting with the nth.

14: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= i
 More than $30 \times N$ iterations are required to determine all the diagonal 1 by 1 or 2 by 2 blocks of the quasi-triangular form in the second step of the QZ algorithm. IFAIL is set to the index i of the eigenvalue at which this failure occurs. If the soft failure option is used, $(\alpha)_j$ and $(\beta)_j$ are correct for $j=i+1, i+2, \dots, n$, but V does not contain any correct eigenvectors.

7. Accuracy

The computed eigenvalues are always exact for a problem $(A+E)x=(\lambda)(B+F)x$ where $\|E\|/\|A\|$ and $\|F\|/\|B\|$ are both of the order of $\max(\text{EPS1}, (\epsilon))$, EPS1 being defined as in Section 5 and (ϵ) being the machine precision.

Note: interpretation of results obtained with the QZ algorithm often requires a clear understanding of the effects of small changes in the original data. These effects are reviewed in Wilkinson [3], in relation to the significance of small values of $(\alpha)_j$ and $(\beta)_j$. It should be noted that if $(\alpha)_j$ and $(\beta)_j$ are both small for any j, it may be that no reliance can be placed on any of the computed eigenvalues $(\lambda)_i = (\alpha)_i / (\beta)_i$. The user is recommended to study [3] and, if in difficulty, to seek expert advice on determining the sensitivity of the eigenvalues to perturbations in the data.

8. Further Comments

3

The time taken by the routine is approximately proportional to n and also depends on the value chosen for parameter EPS1.

9. Example

To find all the eigenvalues and eigenvectors of $Ax=(\lambda) Bx$
where

```
(3.9 12.5 -34.5 -0.5)
(4.3 21.5 -47.5 7.5)
A=(4.3 21.5 -43.5 3.5)
(4.4 26.0 -46.0 6.0)
```

and

```
(1 2 -3 1)
(1 3 -5 4)
B=(1 3 -4 3).
(1 3 -4 4)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02FJF
F02FJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To find eigenvalues and eigenvectors of a real sparse symmetric or generalized symmetric eigenvalue problem.

2. Specification

```
SUBROUTINE F02FJF (N, M, K, NOITS, TOL, DOT, IMAGE, MONIT,
1 NOVECS, X, NRX, D, WORK, LWORK, RWORK,
2 LRWORK, IWORK, LIWORK, IFAIL)
INTEGER N, M, K, NOITS, NOVECS, NRX, LWORK,
1 LRWORK, IWORK(LIWORK), LIWORK, IFAIL
DOUBLE PRECISION TOL, DOT, X(NRX,K), D(K), WORK(LWORK),
1 RWORK(LRWORK)
EXTERNAL DOT, IMAGE, MONIT
```

3. Description

F02FJF finds the m eigenvalues of largest absolute value and the corresponding eigenvectors for the real eigenvalue problem

$$Cx=(\lambda)x \quad (1)$$

where C is an n by n matrix such that

$$BC=C^T B \quad (2)$$

for a given positive-definite matrix B . C is said to be B -symmetric. Different specifications of C allow for the solution of a variety of eigenvalue problems. For example, when

$$C=A \text{ and } B=I \text{ where } A=A^T$$

the routine finds the m eigenvalues of largest absolute magnitude for the standard symmetric eigenvalue problem

$$Ax=(\lambda)x. \quad (3)$$

The routine is intended for the case where A is sparse.

As a second example, when

$$C=B^{-1} A$$

where

$$A=A^T$$

the routine finds the m eigenvalues of largest absolute magnitude for the generalized symmetric eigenvalue problem

$$Ax=(\lambda)Bx. \quad (4)$$

The routine is intended for the case where A and B are sparse.

The routine does not require C explicitly, but C is specified via a user-supplied routine `IMAGE` which, given an n element vector z , computes the image w given by

$$w=Cz.$$

-1

For instance, in the above example, where $C=B^{-1} A$, routine `IMAGE` will need to solve the positive-definite system of equations $Bw=Az$ for w .

To find the m eigenvalues of smallest absolute magnitude of (3)
 -1
 we can choose $C=A^{-1}$ and hence find the reciprocals of the
 required eigenvalues, so that IMAGE will need to solve $Aw=z$ for
 -1
 w , and correspondingly for (4) we can choose $C=A^{-1}B$ and solve
 $Aw=Bz$ for w .

A table of examples of choice of IMAGE is given in Table 3.1. It
 should be remembered that the routine also returns the
 corresponding eigenvectors and that B is positive-definite.
 Throughout A is assumed to be symmetric and, where necessary,
 non-singularity is also assumed.

Eigenvalues Required	Problem		
	$Ax=(\lambda)x$	$(B-I)Ax=(\lambda)Bx$	$ABx=(\lambda)x$
Largest	Compute $w=Az$	Solve $Bw=Az$	Compute $w=ABz$
Smallest (Find $1/(\lambda)$)	Solve $Aw=z$	Solve $Aw=Bz$	Solve $Av=z, Bw=(\lambda)z$
Furthest from (σ) (Find $(\lambda)-(\sigma)$)	Compute $w=(A-(\sigma)I)z$	Solve $Bw=(A-(\sigma)B)z$	Compute $w=(AB-(\sigma)I)z$
Closest to (σ) (Find $1/((\lambda)-(\sigma))$)	Solve $(A-(\sigma)I)w=z$	Solve $(A-(\sigma)B)w=Bz$	Solve $(AB-(\sigma)I)w=z$

Table 3.1
 The Requirement of IMAGE for Various Problems

The matrix B also need not be supplied explicitly, but is
 specified via a user-supplied routine DOT which, given n element
 T
 vectors z and w , computes the generalized dot product $w^T Bz$.

F02FJF is based upon routine SIMITZ (see Nikolai [1]), which is
 itself a derivative of the Algol procedure ritzit (see

Rutishauser [4]), and uses the method of simultaneous (subspace) iteration. (See Parlett [2] for description, analysis and advice on the use of the method.)

The routine performs simultaneous iteration on $k > m$ vectors. Initial estimates to $p \leq k$ eigenvectors, corresponding to the p eigenvalues of C of largest absolute value, may be supplied by the user to F02FJF. When possible k should be chosen so that the k th eigenvalue is not too close to the m required eigenvalues, but if k is initially chosen too small then F02FJF may be re-entered, supplying approximations to the k eigenvectors found so far and with k then increased.

At each major iteration F02FJF solves an r by r ($r \leq k$) eigenvalue sub-problem in order to obtain an approximation to the eigenvalues for which convergence has not yet occurred. This approximation is refined by Chebyshev acceleration.

- [4] Rutishauser H (1970) Simultaneous iteration method for symmetric matrices. Num. Math. 16 205--223.

5. Parameters

- 1: N -- INTEGER Input
On entry: n , the order of the matrix C . Constraint: $N \geq 1$.
- 2: M -- INTEGER Input/Output
On entry: m , the number of eigenvalues required.
,
Constraint: $M \geq 1$. On exit: m , the number of eigenvalues actually found. It is equal to m if IFAIL = 0 on exit, and is less than m if IFAIL = 2, 3 or 4. See Section 6 and Section 8 for further information.
- 3: K -- INTEGER Input
On entry: the number of simultaneous iteration vectors to be used. Too small a value of K may inhibit convergence, while a larger value of K incurs additional storage and additional

work per iteration. Suggested value: $K = M + 4$ will often be a reasonable choice in the absence of better information.
Constraint: $M < K \leq N$.

4: NOITS -- INTEGER Input/Output
On entry: the maximum number of major iterations (eigenvalue sub-problems) to be performed. If NOITS ≤ 0 , then the value 100 is used in place of NOITS. On exit: the number of iterations actually performed.

5: TOL -- DOUBLE PRECISION Input
On entry: a relative tolerance to be used in accepting eigenvalues and eigenvectors. If the eigenvalues are required to about t significant figures, then TOL should be set to about 10^{-t} . d_i is accepted as an eigenvalue as soon as two successive approximations to d_i differ by less than $\frac{1}{2}(|d_i| * TOL)/10$, where d_i is the latest approximation to d_i .
Once an eigenvalue has been accepted, then an eigenvector is accepted as soon as $(d_i f_i)/(d_i - d_k) < TOL$, where f_i is the normalised residual of the current approximation to the eigenvector (see Section 8 for further information). The values of the f_i and d_i can be printed from routine MONIT.
If TOL is supplied outside the range ((epsilon), 1.0), where (epsilon) is the machine precision, then the value (epsilon) is used in place of TOL.

6: DOT -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure
 T
DOT must return the value $w^T B z$ for given vectors w and z .
For the standard eigenvalue problem, where $B=I$, DOT must T
return the dot product $w^T z$.

Its specification is:

```
DOUBLE PRECISION FUNCTION DOT (IFLAG, N, Z, W,
1                                RWORK, LRWORK,
2                                IWORK, LIWORK)
INTEGER                        IFLAG, N, LRWORK, IWORK(LIWORK),
1                                LIWORK
DOUBLE PRECISION Z(N), W(N), RWORK(LRWORK)
```

- 1: IFLAG -- INTEGER Input/Output
 On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of wBz . If IFLAG is negative on exit from DOT, then F02FJF will exit immediately with IFAIL set to IFLAG. Note that in this case DOT must still be assigned a value.
- 2: N -- INTEGER Input
 On entry: the number of elements in the vectors z and w and the order of the matrix B .
- 3: Z(N) -- DOUBLE PRECISION array Input
T
 On entry: the vector z for which wBz is required.
- 4: W(N) -- DOUBLE PRECISION array Input
T
 On entry: the vector w for which wBz is required.
- 5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
- 6: LRWORK -- INTEGER Input
- 7: IWORK(LIWORK) -- INTEGER array User Workspace
- 8: LIWORK -- INTEGER Input
 DOT is called from F02FJF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F02FJF. The user is free to use the arrays RWORK and IWORK to supply information to DOT and to IMAGE as an alternative to using COMMON.
 DOT must be declared as EXTERNAL in the (sub)program from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.
- 7: IMAGE -- SUBROUTINE, supplied by the user. External Procedure
 IMAGE must return the vector $w=Cz$ for a given vector z .
 Its specification is:

```

SUBROUTINE IMAGE (IFLAG, N, Z, W, RWORK, LRWORK,
1                IWORK, LIWORK)
INTEGER          IFLAG, N, LRWORK, IWORK(LIWORK),
1                LIWORK
    
```

DOUBLE PRECISION Z(N), W(N), RWORK(LRWORK)

- 1: IFLAG -- INTEGER Input/Output
 On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of w. If IFLAG is negative on exit from IMAGE, then F02FJF will exit immediately with IFAIL set to IFLAG.

 - 2: N -- INTEGER Input
 On entry: n, the number of elements in the vectors w and z, and the order of the matrix C.

 - 3: Z(N) -- DOUBLE PRECISION array Input
 On entry: the vector z for which Cz is required.

 - 4: W(N) -- DOUBLE PRECISION array Output
 On exit: the vector w=Cz.

 - 5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace

 - 6: LRWORK -- INTEGER Input

 - 7: IWORK(LIWORK) -- INTEGER array User Workspace

 - 8: LIWORK -- INTEGER Input
 IMAGE is called from F02FJF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F02FJF. The user is free to use the arrays RWORK and IWORK to supply information to IMAGE and DOT as an alternative to using COMMON.
 IMAGE must be declared as EXTERNAL in the (sub)program from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.
- 8: MONIT -- SUBROUTINE, supplied by the user. External Procedure
- MONIT is used to monitor the progress of F02FJF. MONIT may be the dummy subroutine F02FJZ if no monitoring is actually required. (F02FJZ is included in the NAG Foundation Library and so need not be supplied by the user. The routine name F02FJZ may be implementation dependent: see the Users' Note for your implementation for details.) MONIT is called after the solution of each eigenvalue sub-problem and also just prior to return from F02FJF. The parameters ISTATE and NEXTIT allow selective printing by MONIT.

Its specification is:

SUBROUTINE MONIT (ISTATE, NEXTIT, NEVALS,

```

1          NEVECS, K, F, D)
  INTEGER      ISTATE, NEXTIT, NEVALS, NEVECS,
1          K
  DOUBLE PRECISION F(K), D(K)

1: ISTATE -- INTEGER                                Input
  On entry: ISTATE specifies the state of F02FJF and will
  have values as follows:
  ISTATE = 0
      No eigenvalue or eigenvector has just been
      accepted.

  ISTATE = 1
      One or more eigenvalues have been accepted since
      the last call to MONIT.

  ISTATE = 2
      One or more eigenvectors have been accepted since
      the last call to MONIT.

  ISTATE = 3
      One or more eigenvalues and eigenvectors have
      been accepted since the last call to MONIT.

  ISTATE = 4
      Return from F02FJF is about to occur.

2: NEXTIT -- INTEGER                                Input
  On entry: the number of the next iteration.

3: NEVALS -- INTEGER                                Input
  On entry: the number of eigenvalues accepted so far.

4: NEVECS -- INTEGER                                Input
  On entry: the number of eigenvectors accepted so far.

5: K -- INTEGER                                     Input
  On entry: k, the number of simultaneous iteration
  vectors.

6: F(K) -- DOUBLE PRECISION array                    Input
  On entry: a vector of error quantities measuring the
  state of convergence of the simultaneous iteration
  vectors. See the parameter TOL of F02FJF above and
  Section 8 for further details. Each element of F is
  initially set to the value 4.0 and an element remains
  at 4.0 until the corresponding vector is tested.

7: D(K) -- DOUBLE PRECISION array                    Input
  On entry: D(i) contains the latest approximation to the

```

absolute value of the i th eigenvalue of C .
 MONIT must be declared as EXTERNAL in the (sub)program
 from which F02FJF is called. Parameters denoted as
 Input must not be changed by this procedure.

- 9: NOVECS -- INTEGER Input
 On entry: the number of approximate vectors that are being
 supplied in X . If NOVECS is outside the range $(0, K)$, then
 the value 0 is used in place of NOVECS.

- 10: $X(NRX, K)$ -- DOUBLE PRECISION array Input/Output
 On entry: if $0 < NOVECS \leq K$, the first NOVECS columns of X
 must contain approximations to the eigenvectors
 corresponding to the NOVECS eigenvalues of largest absolute
 value of C . Supplying approximate eigenvectors can be useful
 when reasonable approximations are known, or when the
 routine is being restarted with a larger value of K .
 Otherwise it is not necessary to supply approximate vectors,
 as simultaneous iteration vectors will be generated randomly
 by the routine. On exit: if IFAIL = 0, 2, 3 or 4, the first
 m' columns contain the eigenvectors corresponding to the
 eigenvalues returned in the first m' elements of D (see
 below); and the next $k - m' - 1$ columns contain approximations
 to the eigenvectors corresponding to the approximate
 eigenvalues returned in the next $k - m' - 1$ elements of D . Here
 m' is the value returned in M (see above), the number of
 eigenvalues actually found. The k th column is used as
 workspace.

- 11: NRX -- INTEGER Input
 On entry:
 the first dimension of the array X as declared in the
 (sub)program from which F02FJF is called.
 Constraint: $NRX \geq N$.

- 12: $D(K)$ -- DOUBLE PRECISION array Output
 On exit: if IFAIL = 0, 2, 3 or 4, the first m' elements
 contain the first m' eigenvalues in decreasing order of
 magnitude; and the next $k - m' - 1$ elements contain
 approximations to the next $k - m' - 1$ eigenvalues. Here m' is
 the value returned in M (see above), the number of
 eigenvalues actually found. $D(k)$ contains the value e where
 $(-e, e)$ is the latest interval over which Chebyshev
 acceleration is performed.

- 13: $WORK(LWORK)$ -- DOUBLE PRECISION array Workspace

- 14: LWORK -- INTEGER Input
 On entry: the length of the array $WORK$, as declared in the
 (sub)program from which F02FJF is called. Constraint:

$LWORK \geq 3 * K + \max(K * K, 2 * N)$.

- 15: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
 RWORK is not used by F02FJF, but is passed directly to
 routines DOT and IMAGE and may be used to supply information
 to these routines.
- 16: LRWORK -- INTEGER Input
 On entry: the length of the array RWORK, as declared in the
 (sub)program from which F02FJF is called. Constraint: LRWORK
 ≥ 1 .
- 17: IWORK(LIWORK) -- INTEGER array User Workspace
 IWORK is not used by F02FJF, but is passed directly to
 routines DOT and IMAGE and may be used to supply information
 to these routines.
- 18: LIWORK -- INTEGER Input
 On entry: the length of the array IWORK, as declared in the
 (sub)program from which F02FJF is called. Constraint: LIWORK
 ≥ 1 .
- 19: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are
 unfamiliar with this parameter should refer to the Essential
 Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
 gives a warning (see Section 6).

For this routine, because the values of output parameters
 may be useful even if IFAIL $\neq$ 0 on exit, users are
 recommended to set IFAIL to -1 before entry. It is then
 essential to test the value of IFAIL on exit. To suppress
 the output of an error message when soft failure occurs, set
 IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL < 0

A negative value of IFAIL indicates an exit from F02FJF
 because the user has set IFLAG negative in DOT or IMAGE. The
 value of IFAIL will be the same as the user's setting of
 IFLAG.

IFAIL = 1

On entry $N < 1$,

or $M < 1$,
or $M \geq K$,
or $K > N$,
or $NRX < N$,
or $LWORK < 3K + \max(K \times K, N)$,
or $LRWORK < 1$,
or $LIWORK < 1$.

IFAIL= 2

Not all the requested eigenvalues and vectors have been obtained. Approximations to the r th eigenvalue are oscillating rapidly indicating that severe cancellation is occurring in the r th eigenvector and so M is returned as $(r-1)$. A restart with a larger value of K may permit convergence.

IFAIL= 3

Not all the requested eigenvalues and vectors have been obtained. The rate of convergence of the remaining eigenvectors suggests that more than $NOITS$ iterations would be required and so the input value of M has been reduced. A restart with a larger value of K may permit convergence.

IFAIL= 4

Not all the requested eigenvalues and vectors have been obtained. $NOITS$ iterations have been performed. A restart, possibly with a larger value of K , may permit convergence.

IFAIL= 5

This error is very unlikely to occur, but indicates that convergence of the eigenvalue sub-problem has not taken place. Restarting with a different set of approximate vectors may allow convergence. If this error occurs the user should check carefully that F02FJF is being called correctly.

7. Accuracy

Eigenvalues and eigenvectors will normally be computed to the accuracy requested by the parameter TOL , but eigenvectors corresponding to small or to close eigenvalues may not always be computed to the accuracy requested by the parameter TOL . Use of the routine **MONIT** to monitor acceptance of eigenvalues and

eigenvectors is recommended.

8. Further Comments

The time taken by the routine will be principally determined by the time taken to solve the eigenvalue sub-problem and the time taken by the routines DOT and IMAGE. The time taken to solve an eigenvalue sub-problem is approximately proportional to n^2 . It is important to be aware that several calls to DOT and IMAGE may occur on each major iteration.

As can be seen from Table 3.1, many applications of F02FJF will require routine IMAGE to solve a system of linear equations. For example, to find the smallest eigenvalues of $Ax=(\lambda)Bx$, IMAGE needs to solve equations of the form $Aw=Bz$ for w and routines from Chapters F01 and F04 of the NAG Foundation Library will frequently be useful in this context. In particular, if A is a positive-definite variable band matrix, F04MCF may be used after A has been factorized by F01MCF. Thus factorization need be performed only once prior to calling F02FJF. An illustration of this type of use is given in the example program in Section 9.

An approximation d_h , to the i th eigenvalue, is accepted as soon

as d_h and the previous approximation differ by less than

$|d_h|*TOL/10$. Eigenvectors are accepted in groups corresponding to

clusters of eigenvalues that are equal, or nearly equal, in absolute value and that have already been accepted. If d_r is the last eigenvalue in such a group and we define the residual r_j as

$$r_j = Cx_j - y_r$$

where y_r is the projection of Cx_j , with respect to B , onto the space spanned by $x_1, x_2, \dots, x_r$ and x_j is the current approximation to the j th eigenvector, then the value f_i returned in MONIT is given by

$$f_i = \max_j \frac{\|r_j\|}{\|Cx_j\|} \quad \|x\| = x B$$

and each vector in the group is accepted as an eigenvector if

$$\frac{(\|d_r\| f_r)}{(\|d_r\| - e)} < \text{TOL}$$

where e is the current approximation to $\|d_k\|$. The values of the f_i are systematically increased if the convergence criteria

appear to be too strict. See Rutishauser [4] for further details.

The algorithm implemented by F02FJF differs slightly from SIMITZ (Nikolai [1]) in that the eigenvalue sub-problem is solved using the singular value decomposition of the upper triangular matrix R^T of the Gram-Schmidt factorization of Cx , rather than forming $R R^T$.

9. Example

To find the four eigenvalues of smallest absolute value and corresponding eigenvectors for the generalized symmetric eigenvalue problem $Ax = (\lambda B)x$, where A and B are the 16 by 16 matrices

$$A = \begin{pmatrix} 1 & a & & & & & & & & & & & & & & \\ a & 1 & a & & & & & & & & & & & & & \\ & a & 1 & a & & & & & & & & & & & & \\ & & a & 1 & a & & & & & & & & & & & \\ a & & & a & 1 & a & & & & & & & & & & \\ & a & & & a & 1 & a & & & & & & & & & \\ & & a & & & a & 1 & a & & & & & & & & \\ & & & a & & & a & 1 & a & & & & & & & \\ & & & & a & & & a & 1 & a & & & & & & \\ & & & & & a & & & a & 1 & a & & & & & \\ & & & & & & a & & & a & 1 & a & & & & \\ & & & & & & & a & & & a & 1 & a & & & \\ & & & & & & & & a & & & a & 1 & a & & \\ & & & & & & & & & a & & & a & 1 & a & \\ & & & & & & & & & & a & & & a & 1 & \end{pmatrix}$$

where $a = -\frac{1}{4}$

```

( b 1 b )
( b 1 b )
( b 1 b )
( b 1 b )

```

```

1
where b= -
2

```

TOL is taken as 0.0001 and 6 iteration vectors are used. F01MAF is used to factorize the matrix A, prior to calling F02FJF, and F04MAF is used within IMAGE to solve the equations $Aw=Bz$ for w . Details of the factorization of A are passed from F01MAF to F04MAF by means of the COMMON block BLOCK1.

Output from MONIT occurs each time ISTATE is non-zero. Note that the required eigenvalues are the reciprocals of the eigenvalues returned by F02FJF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors                                F02WEF
F02WEF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02WEF returns all, or part, of the singular value decomposition of a general real matrix.

2. Specification

```

      SUBROUTINE FO2WEF (M, N, A, LDA, NCOLB, B, LDB, WANTQ, Q,
1                      LDQ, SV, WANTP, PT, LDPT, WORK, IFAIL)
      INTEGER          M, N, LDA, NCOLB, LDB, LDQ, LDPT, IFAIL
      DOUBLE PRECISION A(LDA,*), B(LDB,*), Q(LDQ,*), SV(*), PT
1                      (LDPT,*), WORK(*)
      LOGICAL          WANTQ, WANTP

```

3. Description

The m by n matrix A is factorized as

$$A = QDP^T,$$

where

$$\begin{aligned}
 D &= (0), & m > n, \\
 D &= S, & m = n, \\
 D &= (S \ 0), & m < n,
 \end{aligned}$$

Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and S is a $\min(m,n)$ by $\min(m,n)$ diagonal matrix with non-negative diagonal elements, $sv_1, sv_2, \dots, sv_{\min(m,n)}$, ordered such that

$$sv_1 \geq sv_2 \geq \dots \geq sv_{\min(m,n)} \geq 0.$$

The first $\min(m,n)$ columns of Q are the left-hand singular vectors of A , the diagonal elements of S are the singular values of A and the first $\min(m,n)$ columns of P are the right-hand singular vectors of A .

Either or both of the left-hand and right-hand singular vectors of A may be requested and the matrix C given by

$$C = Q^T B,$$

where B is an m by $ncolb$ given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing A to upper triangular form by means of Householder transformations, from the left when $m \geq n$ and from the right when $m < n$. The upper triangular form is then reduced to bidiagonal form

by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] DSVDC.

Note that if K is any orthogonal diagonal matrix so that

$$K^T K = I,$$

(so that K has elements $+1$ or -1 on the diagonal)

then

$$A = (QK)D(PK)^T$$

is also a singular value decomposition of A .

5. Parameters

- 1: M -- INTEGER Input
 On entry: the number of rows, m , of the matrix A .
 Constraint: $M \geq 0$.

 When $M = 0$ then an immediate return is effected.
- 2: N -- INTEGER Input
 On entry: the number of columns, n , of the matrix A .
 Constraint: $N \geq 0$.

 When $N = 0$ then an immediate return is effected.
- 3: $A(LDA,*)$ -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array A must be at least $\max(1, N)$.

On entry: the leading m by n part of the array A must contain the matrix A whose singular value decomposition is required. On exit: if $M \geq N$ and $WANTQ = .TRUE.$, then the leading m by n part of A will contain the first n columns of the orthogonal matrix Q .

If $M < N$ and $WANTP = .TRUE.$, then the leading m by n part of A will contain the first m rows of the orthogonal matrix P^T .

If $M \geq N$ and $WANTQ = .FALSE.$ and $WANTP = .TRUE.$, then the leading n by n part of A will contain the first n rows of the orthogonal matrix P^T .

Otherwise the leading m by n part of A is used as internal workspace.

- 4: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02WEF is called.
 Constraint: $LDA \geq \max(1, M)$.

- 5: NCOLB -- INTEGER Input
 On entry: $ncolb$, the number of columns of the matrix B .
 When $NCOLB = 0$ the array B is not referenced. Constraint:
 $NCOLB \geq 0$.

- 6: B(LDB,*) -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array B must be at least $\max(1, ncolb)$ On entry: if $NCOLB > 0$, the leading m by $ncolb$ part of the array B must contain the matrix to be transformed. On exit: B is overwritten by the m by $ncolb$ matrix $Q^T B$.

- 7: LDB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the (sub)program from which F02WEF is called.
 Constraint: if $NCOLB > 0$ then $LDB \geq \max(1, M)$.

- 8: WANTQ -- LOGICAL Input
 On entry: $WANTQ$ must be $.TRUE.$, if the left-hand singular vectors are required. If $WANTQ = .FALSE.$, then the array Q is not referenced.

- 9: Q(LDQ,*) -- DOUBLE PRECISION array Output
 Note: the second dimension of the array Q must be at least

$\max(1,M)$.

On exit: if $M < N$ and $\text{WANTQ} = \text{.TRUE.}$, the leading m by m part of the array Q will contain the orthogonal matrix Q . Otherwise the array Q is not referenced.

- 10: LDQ -- INTEGER Input
 On entry:
 the first dimension of the array Q as declared in the (sub)program from which F02WEF is called.
 Constraint: if $M < N$ and $\text{WANTQ} = \text{.TRUE.}$, $\text{LDQ} \geq \max(1,M)$.
- 11: SV(*) -- DOUBLE PRECISION array Output
 Note: the length of SV must be at least $\min(M,N)$. On exit: the $\min(M,N)$ diagonal elements of the matrix S .
- 12: WANTP -- LOGICAL Input
 On entry: WANTP must be .TRUE. if the right-hand singular vectors are required. If $\text{WANTP} = \text{.FALSE.}$, then the array PT is not referenced.
- 13: PT(LDPT,*) -- DOUBLE PRECISION array Output
 Note: the second dimension of the array PT must be at least $\max(1,N)$.
 On exit: if $M \geq N$ and WANTQ and WANTP are .TRUE. , the leading n by n part of the array PT will contain the

$$P^T$$

 orthogonal matrix P . Otherwise the array PT is not referenced.
- 14: LDPT -- INTEGER Input
 On entry:
 the first dimension of the array PT as declared in the (sub)program from which F02WEF is called.
 Constraint: if $M \geq N$ and WANTQ and WANTP are .TRUE. , $\text{LDPT} \geq \max(1,N)$.
- 15: WORK(*) -- DOUBLE PRECISION array Output
 Note: the length of $WORK$ must be at least $\max(1,\text{lwork})$, where lwork must be as given in the following table:
- | |
|--|
| $M \geq N$ |
| WANTQ is .TRUE. and $\text{WANTP} = \text{.TRUE.}$ |
| 2 |
| $\text{lwork} = \max(N + 5*(N-1), N + \text{NCOLB}, 4)$ |
| $\text{WANTQ} = \text{.TRUE.}$ and $\text{WANTP} = \text{.FALSE.}$ |
| 2 |
| $\text{lwork} = \max(N + 4*(N-1), N + \text{NCOLB}, 4)$ |
| $\text{WANTQ} = \text{.FALSE.}$ and $\text{WANTP} = \text{.TRUE.}$ |

```

      lwork=max(3*(N-1),2) when NCOLB = 0

      lwork=max(5*(N-1),2) when NCOLB > 0

WANTQ = .FALSE. and WANTP = .FALSE.
      lwork=max(2*(N-1),2) when NCOLB = 0

      lwork=max(3*(N-1),2) when NCOLB > 0

M < N
WANTQ = .TRUE. and WANTP = .TRUE.
      2
      lwork=max(M +5*(M-1),2)

WANTQ = .TRUE. and WANTP = .FALSE.
      lwork=max(3*(M-1),1)

WANTQ = .FALSE. and WANTP = .TRUE.
      2
      lwork=max(M +3*(M-1),2) when NCOLB = 0

      2
      lwork=max(M +5*(M-1),2) when NCOLB > 0

WANTQ = .FALSE. and WANTP = .FALSE.
      lwork=max(2*(M-1),1) when NCOLB = 0

      lwork=max(3*(M-1),1) when NCOLB > 0
On exit: WORK(min(M,N)) contains the total number of
iterations taken by the R algorithm.

```

The rest of the array is used as workspace.

16: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL=-1

One or more of the following conditions holds:

```

M < 0,

N < 0,

LDA < M,

NCOLB < 0,

LDB < M and NCOLB > 0,

LDQ < M and M < N and WANTQ = .TRUE.,

LDPT < N and M >= N and WANTQ = .TRUE., and WANTP = .
TRUE..

```

IFAIL> 0

The QR algorithm has failed to converge in 50*min(m,n) iterations. In this case SV(1), SV(2),..., SV(IFAIL) may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have

T

been factorized as $A=QEP$, where the leading min(m,n) by min(m,n) part of E is a bidiagonal matrix with SV(1), SV(2), ..., SV(min(m,n)) as the diagonal elements and WORK(1), WORK(2),..., WORK(min(m,n)-1) as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors Q, D and P satisfy the relation

$$QDP^T = A + E,$$

where

$$||E|| \leq c(\text{epsilon}) ||A||,$$

(epsilon) being the machine precision, c is a modest function of m and n and ||.|| denotes the spectral (two) norm. Note that $||A|| = \text{sv}_1$.

1

8. Further Comments

Following the use of this routine the rank of A may be estimated by a call to the INTEGER FUNCTION F06KLF(*). The statement:

```
IRANK = F06KLF(MIN(M, N), SV, 1, TOL)
```

returns the value (k-1) in IRANK, where k is the smallest integer for which $SV(k) < tol * SV(1)$, where tol is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of S and thus also of A. If TOL is supplied as negative then the machine precision is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

```
(2.0  2.5  2.5)
(2.0  2.5  2.5)
A=(1.6 -0.4  2.8)
(2.0 -0.5  0.5)
(1.2 -0.3 -2.9)
```

T

together with the vector Q b for the vector

```
( 1.1)
( 0.9)
b=( 0.6)
( 0.0)
(-0.8)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

9.2. Example 2

To find the singular value decomposition of the 3 by 5 matrix

```
(2.0 2.0  1.6  2.0  1.2)
A=(2.5 2.5 -0.4 -0.5 -0.3)
(2.5 2.5  2.8  0.5 -2.9)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

    DOUBLE PRECISION SV(*), RWORK(*)
    COMPLEX(KIND=KIND(1.0D0)) A(LDA,*), B(LDB,*), Q(LDQ,*),
1                PH(LDPH,*), CWORK(*)
    LOGICAL          WANTQ, WANTP

```

3. Description

The m by n matrix A is factorized as

$$A = QDP^H,$$

where

$$\begin{aligned}
 D &= \begin{pmatrix} S \\ 0 \end{pmatrix} & m > n, \\
 D &= S, & m = n, \\
 D &= \begin{pmatrix} S & 0 \end{pmatrix}, & m < n,
 \end{aligned}$$

Q is an m by m unitary matrix, P is an n by n unitary matrix and S is a $\min(m,n)$ by $\min(m,n)$ diagonal matrix with real non-negative diagonal elements, $sv_1, sv_2, \dots, sv_{\min(m,n)}$, ordered such

that

$$sv_1 \geq sv_2 \geq \dots \geq sv_{\min(m,n)} \geq 0.$$

The first $\min(m,n)$ columns of Q are the left-hand singular vectors of A , the diagonal elements of S are the singular values of A and the first $\min(m,n)$ columns of P are the right-hand singular vectors of A .

Either or both of the left-hand and right-hand singular vectors of A may be requested and the matrix C given by

$$C = Q^H B,$$

where B is an m by ncolb given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing A to upper triangular form by means of Householder transformations, from the left when $m \geq n$ and from the right when $m < n$. The upper triangular form is then reduced to bidiagonal form by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] ZSVDC.

Note that if K is any unitary diagonal matrix so that

$$K K^H = I,$$

then

$$A = (QK) D (PK)^H$$

is also a singular value decomposition of A.

 Note: the second dimension of the array B must be at least $\max(1, NCOLB)$.
 On entry: if $NCOLB > 0$, the leading m by $ncolb$ part of the array B must contain the matrix to be transformed. On exit:
 B is overwritten by the m by $ncolb$ matrix $Q B$.

- 7: LDB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the (sub)program from which F02XEF is called.
 Constraint: if $NCOLB > 0$, then $LDB \geq \max(1, M)$.

- 8: WANTQ -- LOGICAL Input
 On entry: WANTQ must be .TRUE. if the left-hand singular
 vectors are required. If WANTQ = .FALSE. then the array Q is
 not referenced.
- 9: Q(LDQ,*) -- COMPLEX(KIND(1.0D)) array Output
 Note: the second dimension of the array Q must be at least
 max(1,M).
 On exit: if $M < N$ and WANTQ = .TRUE., the leading m by m
 part of the array Q will contain the unitary matrix Q.
 Otherwise the array Q is not referenced.
- 10: LDQ -- INTEGER Input
 On entry:
 the first dimension of the array Q as declared in the
 (sub)program from which F02XEF is called.
 Constraint: if $M < N$ and WANTQ = .TRUE., $LDQ \geq \max(1,M)$.
- 11: SV(*) -- DOUBLE PRECISION array Output
 Note: the length of SV must be at least min(M,N). On exit:
 the min(m,n) diagonal elements of the matrix S.
- 12: WANTP -- LOGICAL Input
 On entry: WANTP must be .TRUE. if the right-hand singular
 vectors are required. If WANTP = .FALSE. then the array PH
 is not referenced.
- 13: PH(LDPH,*) -- DOUBLE PRECISION array Output
 Note: the second dimension of the array PH must be at least
 max(1,N).
 On exit: if $M \geq N$ and WANTQ and WANTP are .TRUE., the
 leading n by n part of the array PH will contain the unitary
 H
 matrix P. Otherwise the array PH is not referenced.
- 14: LDPH -- INTEGER Input
 On entry:
 the first dimension of the array PH as declared in the
 (sub)program from which F02XEF is called.
 Constraint: if $M \geq N$ and WANTQ and WANTP are .TRUE., $LDPH$
 $\geq \max(1,N)$.
- 15: RWORK(*) -- DOUBLE PRECISION array Output
 Note: the length of RWORK must be at least max(1,lrwork),
 where lrwork must satisfy:
 $lrwork = 2 * (\min(M,N) - 1)$ when
 $NCOLB = 0$ and WANTQ and WANTP are .FALSE.,
 $lrwork = 3 * (\min(M,N) - 1)$ when

either $NCOLB = 0$ and $WANTQ = .FALSE.$ and $WANTP = .TRUE.$, or $WANTP = .FALSE.$ and one or both of $NCOLB > 0$ and $WANTQ = .TRUE.$

$lrwork = 5 * (\min(M, N) - 1)$
otherwise.

On exit: $RWORK(\min(M, N))$ contains the total number of iterations taken by the QR algorithm.

The rest of the array is used as workspace.

16: $CWORK(*)$ -- $COMPLEX(KIND(1.0D))$ array Workspace

Note: the length of $CWORK$ must be at least $\max(1, lcwork)$, where $lcwork$ must satisfy:

2
 $lcwork = N + \max(N, NCOLB)$ when
 $M \geq N$ and $WANTQ$ and $WANTP$ are both $.TRUE.$

2
 $lcwork = N + \max(N + N, NCOLB)$ when
 $M \geq N$ and $WANTQ = .TRUE.$, but $WANTP = .FALSE.$

$lcwork = N + \max(N, NCOLB)$ when
 $M \geq N$ and $WANTQ = .FALSE.$

2
 $lcwork = M + M$ when
 $M < N$ and $WANTP = .TRUE.$

$lcwork = M$ when
 $M < N$ and $WANTP = .FALSE.$

17: $IFAIL$ -- $INTEGER$ Input/Output

On entry: $IFAIL$ must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: $IFAIL = 0$ unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry $IFAIL = 0$ or -1, explanatory error messages are output on the current error message unit (as defined by $X04AAF$).

$IFAIL = -1$

One or more of the following conditions holds:
 $M < 0$,

```

N < 0,

LDA < M,

NCOLB < 0,

LDB < M and NCOLB > 0,

LDQ < M and M < N and WANTQ = .TRUE.,

LDPH < N and M >= N and WANTQ = .TRUE. and WANTP = .
TRUE..

```

IFAIL > 0

The QR algorithm has failed to converge in $50 \times \min(m,n)$ iterations. In this case SV(1), SV(2), ..., SV(IFAIL) may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have

H

been factorized as $A = QEP$ where the leading $\min(m,n)$ by $\min(m,n)$ part of E is a bidiagonal matrix with SV(1), SV(2), ..., SV($\min(m,n)$) as the diagonal elements and RWORK(1), RWORK(2), ..., RWORK($\min(m,n)-1$) as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors Q, D and P satisfy the relation

$$QDP = A + E,$$

where

$$\|E\| \leq c(\text{epsilon}) \|A\|,$$

(epsilon) being the machine precision, c is a modest function of m and n and $\|.\|$ denotes the spectral (two) norm. Note that $\|A\| = \text{sv}_1$.

1

8. Further Comments

Following the use of this routine the rank of A may be estimated by a call to the INTEGER FUNCTION F06KLF(*). The statement:

```
IRANK = F06KLF(MIN(M, N), SV, 1, TOL)
```

returns the value (k-1) in IRANK, where k is the smallest integer for which $SV(k) < tol * SV(1)$, where tol is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of S and thus also of A. If TOL is supplied as negative then the machine precision is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

```
( 0.5i -0.5+1.5i -1.0+1.0i)
(0.4+0.3i 0.9+1.3i 0.2+1.4i)
A=(0.4      -0.4+0.4i 1.8      )
(0.3-0.4i 0.1+0.7i 0.0      )
( -0.3i 0.3+0.3i      2.4i)
```

H

together with the vector Q b for the vector

```
(-0.55+1.05i)
( 0.49+0.93i)
b=( 0.56-0.16i)
( 0.39+0.23i)
( 1.13+0.83i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

9.2. Example 2

To find the singular value decomposition of the 3 by 5 matrix

```
( 0.5i 0.4-0.3i 0.4      0.3+0.4i 0.3i)
A=(-0.5-1.5i 0.9-1.3i -0.4-0.4i 0.1-0.7i 0.3-0.3i)
(-1.0-1.0i 0.2-1.4i 1.8      0.0      -2.4i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

f02aaf : (Integer,Integer,Matrix DoubleFloat,Integer) -> Result
++ f02aaf(ia,n,a,ifail)
++ calculates all the eigenvalue.
++ See \downlink{Manual Page}{manpageXXf02aaf}.

f02abf : (Matrix DoubleFloat,Integer,Integer,Integer,Integer) -> Result
++ f02abf(a,ia,n,iv,ifail)
++ calculates all the eigenvalues of a real
++ symmetric matrix.

```

```

++ See \downlink{Manual Page}{manpageXXf02abf}.

f02adf : (Integer,Integer,Integer,Matrix DoubleFloat,_
  Matrix DoubleFloat,Integer) -> Result
++ f02adf(ia,ib,n,a,b,ifail)
++ calculates all the eigenvalues of  $Ax=(\lambda)Bx$ , where A
++ is a real symmetric matrix and B is a real symmetric positive-
++ definite matrix.
++ See \downlink{Manual Page}{manpageXXf02adf}.

f02aef : (Integer,Integer,Integer,Integer,_
  Matrix DoubleFloat,Matrix DoubleFloat,Integer) -> Result
++ f02aef(ia,ib,n,iv,a,b,ifail)
++ calculates all the eigenvalues of
++  $Ax=(\lambda)Bx$ , where A is a real symmetric matrix and B is a
++ real symmetric positive-definite matrix.
++ See \downlink{Manual Page}{manpageXXf02aef}.

f02aff : (Integer,Integer,Matrix DoubleFloat,Integer) -> Result
++ f02aff(ia,n,a,ifail)
++ calculates all the eigenvalues of a real unsymmetric
++ matrix.
++ See \downlink{Manual Page}{manpageXXf02aff}.

f02agf : (Integer,Integer,Integer,Integer,_
  Matrix DoubleFloat,Integer) -> Result
++ f02agf(ia,n,ivr,ivi,a,ifail)
++ calculates all the eigenvalues of a real
++ unsymmetric matrix.
++ See \downlink{Manual Page}{manpageXXf02agf}.

f02ajf : (Integer,Integer,Integer,Matrix DoubleFloat,_
  Matrix DoubleFloat,Integer) -> Result
++ f02ajf(iar,iai,n,ar,ai,ifail)
++ calculates all the eigenvalue.
++ See \downlink{Manual Page}{manpageXXf02ajf}.

f02akf : (Integer,Integer,Integer,Integer,_
  Integer,Matrix DoubleFloat,Matrix DoubleFloat,Integer) -> Result
++ f02akf(iar,iai,n,ivr,ivi,ar,ai,ifail)
++ calculates all the eigenvalues of a
++ complex matrix.
++ See \downlink{Manual Page}{manpageXXf02akf}.

f02awf : (Integer,Integer,Integer,Matrix DoubleFloat,_
  Matrix DoubleFloat,Integer) -> Result
++ f02awf(iar,iai,n,ar,ai,ifail)
++ calculates all the eigenvalues of a complex Hermitian
++ matrix.
++ See \downlink{Manual Page}{manpageXXf02awf}.

```

```

f02axf : (Matrix DoubleFloat,Integer,Matrix DoubleFloat,Integer,_
Integer,Integer,Integer,Integer) -> Result
++ f02axf(ar,iar,ai,iai,n,ivr,ivi,ifail)
++ calculates all the eigenvalues of a
++ complex Hermitian matrix.
++ See \downlink{Manual Page}{manpageXXf02axf}.

f02bbf : (Integer,Integer,DoubleFloat,DoubleFloat,_
Integer,Integer,Matrix DoubleFloat,Integer) -> Result
++ f02bbf(ia,n,alb,ub,m,iv,a,ifail)
++ calculates selected eigenvalues of a real
++ symmetric matrix by reduction to tridiagonal form, bisection and
++ inverse iteration, where the selected eigenvalues lie within a
++ given interval.
++ See \downlink{Manual Page}{manpageXXf02bbf}.

f02bjf : (Integer,Integer,Integer,DoubleFloat,_
Boolean,Integer,Matrix DoubleFloat,Matrix DoubleFloat,Integer) -> Result
++ f02bjf(n,ia,ib,eps1,matv,iv,a,b,ifail)
++ calculates all the eigenvalues and, if required, all the
++ eigenvectors of the generalized eigenproblem  $Ax=(\lambda)Bx$ 
++ where A and B are real, square matrices, using the QZ algorithm.
++ See \downlink{Manual Page}{manpageXXf02bjf}.

f02fjf : (Integer,Integer,DoubleFloat,Integer,_
Integer,Integer,Integer,Integer,Integer,Integer,Matrix DoubleFloat,_
Integer,Union(fn:FileName,fp:Asp27(DOT)),_
Union(fn:FileName,fp:Asp28(IMAGE))) -> Result
++ f02fjf(n,k,tol,novecs,nrx,lwork,lrwork,
++      liwork,m,noits,x,ifail,dot,image)
++ finds eigenvalues of a real sparse symmetric
++ or generalized symmetric eigenvalue problem.
++ See \downlink{Manual Page}{manpageXXf02fjf}.

f02fjf : (Integer,Integer,DoubleFloat,Integer,_
Integer,Integer,Integer,Integer,Integer,Integer,Matrix DoubleFloat,_
Integer,Union(fn:FileName,fp:Asp27(DOT)),_
Union(fn:FileName,fp:Asp28(IMAGE)),FileName) -> Result
++ f02fjf(n,k,tol,novecs,nrx,lwork,lrwork,
++      liwork,m,noits,x,ifail,dot,image,monit)
++ finds eigenvalues of a real sparse symmetric
++ or generalized symmetric eigenvalue problem.
++ See \downlink{Manual Page}{manpageXXf02fjf}.

f02wef : (Integer,Integer,Integer,Integer,_
Integer,Boolean,Integer,Boolean,Integer,Matrix DoubleFloat,_
Matrix DoubleFloat,Integer) -> Result
++ f02wef(m,n,lda,ncolb,ldb,wantq,ldq,wantp,ldpt,a,b,ifail)
++ returns all, or part, of the singular value decomposition

```

```

++ of a general real matrix.
++ See \downlink{Manual Page}{manpageXXf02wef}.

f02xef : (Integer,Integer,Integer,Integer,_
         Integer,Boolean,Integer,Boolean,Integer,Matrix Complex DoubleFloat,_
         Matrix Complex DoubleFloat,Integer) -> Result
++ f02xef(m,n,lda,ncolb,ldb,wantq,ldq,wantp,ldph,a,b,ifail)
++ returns all, or part, of the singular value decomposition
++ of a general complex matrix.
++ See \downlink{Manual Page}{manpageXXf02xef}.

— NagFittingPackage.help —

This package uses the NAG Library to find a function which approximates a set of data points. Typically the data contain random errors, as of experimental measurement, which need to be smoothed out. To seek an approximation to the data, it is first necessary to specify for the approximating function a mathematical form (a polynomial, for example) which contains a number of unspecified coefficients: the appropriate fitting routine then derives for the coefficients the values which provide the best fit of that particular form. The package deals mainly with curve and surface fitting (fitting with functions of one and of two variables) when a polynomial or a cubic spline is used as the fitting function, since these cover the most common needs. However, fitting with other functions and/or more variables can be undertaken by means of general linear or nonlinear routines (some of which are contained in other packages) depending on whether the coefficients in the function occur linearly or nonlinearly. Cases where a graph rather than a set of data points is given can be treated simply by first reading a suitable set of points from the graph. The package also contains routines for evaluating, differentiating and integrating polynomial and spline

curves and surfaces, once the numerical values of their coefficients have been determined.

1. Scope of the Chapter

The main aim of this chapter is to assist the user in finding a function which approximates a set of data points. Typically the data contain random errors, as of experimental measurement, which need to be smoothed out. To seek an approximation to the data, it is first necessary to specify for the approximating function a mathematical form (a polynomial, for example) which contains a number of unspecified coefficients: the appropriate fitting routine then derives for the coefficients the values which provide the best fit of that particular form. The chapter deals mainly with curve and surface fitting (fitting with functions of one and of two variables) when a polynomial or a cubic spline is used as the fitting function, since these cover the most common needs. However, fitting with other functions and/or more variables can be undertaken by means of general linear or nonlinear routines (some of which are contained in other chapters) depending on whether the coefficients in the function occur linearly or nonlinearly. Cases where a graph rather than a set of data points is given can be treated simply by first reading a suitable set of points from the graph.

The chapter also contains routines for evaluating, differentiating and integrating polynomial and spline curves and surfaces, once the numerical values of their coefficients have

been determined.

2. Background to the Problems

2.1. Preliminary Considerations

In the curve-fitting problems considered in this chapter, we have a dependent variable y and an independent variable x , and we are given a set of data points (x_r, y_r) , for $r=1,2,\dots,m$. The

preliminary matters to be considered in this section will, for simplicity, be discussed in this context of curve-fitting problems. In fact, however, these considerations apply equally well to surface and higher-dimensional problems. Indeed, the discussion presented carries over essentially as it stands if, for these cases, we interpret x as a vector of several independent variables and correspondingly each x_r as a vector containing the r th data value of each independent variable.

We wish, then, to approximate the set of data points as closely as possible with a specified function, $f(x)$ say, which is as smooth as possible -- $f(x)$ may, for example, be a polynomial. The requirements of smoothness and closeness conflict, however, and a balance has to be struck between them. Most often, the smoothness requirement is met simply by limiting the number of coefficients allowed in the fitting function -- for example, by restricting the degree in the case of a polynomial. Given a particular number of coefficients in the function in question, the fitting routines of this chapter determine the values of the coefficients such that the 'distance' of the function from the data points is as small as possible. The necessary balance is struck by the user comparing a selection of such fits having different numbers of coefficients. If the number of coefficients is too low, the approximation to the data will be poor. If the number is too high, the fit will be too close to the data, essentially following the random errors and tending to have unwanted fluctuations between the data points. Between these extremes, there is often a group of fits all similarly close to the data points and then, particularly when least-squares polynomials are used, the choice is clear: it is the fit from this group having the smallest number of coefficients.

The above process can be seen as the user minimizing the smoothness measure (the number of coefficients) subject to the distance from the data points being acceptably small. Some of the routines, however, do this task themselves. They use a different measure of smoothness (in each case one that is continuous) and minimize it subject to the distance being less than a threshold specified by the user. This is a much more

automatic process, requiring only some experimentation with the threshold.

2.1.1. Fitting criteria: norms

A measure of the above 'distance' between the set of data points and the function $f(x)$ is needed. The distance from a single data point (x_r, y_r) to the function can simply be taken as

$$r_r$$

$$(\text{epsilon})_r = y_r - f(x_r), \quad (1)$$

and is called the residual of the point. (With this definition, the residual is regarded as a function of the coefficients contained in $f(x)$; however, the term is also used to mean the particular value of $(\text{epsilon})_r$ which corresponds to the fitted

r

values of the coefficients.) However, we need a measure of distance for the set of data points as a whole. Three different measures are used in the different routines (which measure to select, according to circumstances, is discussed later in this sub-section). With $(\text{epsilon})_r$ defined in (1), these measures, or

r

norms, are

$$\begin{aligned} & \text{m} \\ & \text{--} \\ & > |(\text{epsilon})_r|, \quad (2) \\ & \text{--} \\ & r=1 \end{aligned}$$

$$\begin{aligned} & / \text{ m} \\ & / \text{ --} \\ & / > (\text{epsilon})_r^2, \text{ and} \quad (3) \\ & / \text{ --} \\ & \backslash / r=1 \end{aligned}$$

$$\begin{aligned} & \max |(\text{epsilon})_r|, \quad (4) \\ & r \end{aligned}$$

respectively the l_1 norm, the l_2 norm and the l_{∞} norm.

Minimization of one or other of these norms usually provides the fitting criterion, the minimization being carried out with respect to the coefficients in the mathematical form used for $f(x)$: with respect to the b for example if the mathematical form

is the power series in (8) below. The fit which results from minimizing (2) is known as the l_1 fit, or the fit in the l_1 norm: that which results from minimizing (3) is the l_2 fit, the well-known least-squares fit (minimizing (3) is equivalent to minimizing the square of (3), the sum of squares of residuals, and it is the latter which is used in practice), and that from minimizing (4) is the l_∞ , or minimax, fit.

Strictly speaking, implicit in the use of the above norms are the statistical assumptions that the random errors in the y are independent of one another and that any errors in the x are negligible by comparison. From this point of view, the use of the l_1 norm is appropriate when the random errors in the y have a normal distribution, and the l_2 norm is appropriate when they have a rectangular distribution, as when fitting a table of values rounded to a fixed number of decimal places. The l_1 norm is appropriate when the error distribution has its frequency function proportional to the negative exponential of the modulus of the normalised error -- not a common situation.

However, the user is often indifferent to these statistical considerations, and simply seeks a fit which he can assess by inspection, perhaps visually from a graph of the results. In this event, the l_1 norm is particularly appropriate when the data are thought to contain some 'wild' points (since fitting in this norm tends to be unaffected by the presence of a small number of such points), though of course in simple situations the user may prefer to identify and reject these points. The l_∞ norm should be used only when the maximum residual is of particular concern, as may be the case for example when the data values have been obtained by accurate computation, as of a mathematical function. Generally, however, a routine based on least-squares should be preferred, as being computationally faster and usually providing more information on which to assess the results. In many problems the three fits will not differ significantly for practical purposes.

Some of the routines based on the l_2 norm do not minimize the

norm itself but instead minimize some (intuitively acceptable) measure of smoothness subject to the norm being less than a user-specified threshold. These routines fit with cubic or bicubic splines (see (10) and (14) below) and the smoothing measures relate to the size of the discontinuities in their third derivatives. A much more automatic fitting procedure follows from this approach.

2.1.2. Weighting of data points

The use of the above norms also assumes that the data values y_r are of equal (absolute) accuracy. Some of the routines enable an allowance to be made to take account of differing accuracies. The allowance takes the form of 'weights' applied to the y -values so that those values known to be more accurate have a greater influence on the fit than others. These weights, to be supplied by the user, should be calculated from estimates of the absolute accuracies of the y -values, these estimates being expressed as standard deviations, probable errors or some other measure which has the same dimensions as y . Specifically, for each y_r the corresponding weight w_r should be inversely proportional to the accuracy estimate of y_r . For example, if the percentage accuracy is the same for all y_r , then the absolute accuracy of y_r is proportional to y_r (assuming y_r to be positive, as it usually is in such cases) and so $w_r = K/y_r$, for $r=1,2,\dots,m$, for an arbitrary positive constant K . (This definition of weight is stressed because often weight is defined as the square of that used here.) The norms (2), (3) and (4) above are then replaced respectively by

$$\sum_{r=1}^m |w_r(\epsilon)|, \quad (5)$$

$$\sum_{r=1}^m w_r^2(\epsilon), \quad \text{and} \quad \sqrt{\sum_{r=1}^m w_r^2(\epsilon)}, \quad (6)$$

$$\max_r |w_r(\epsilon)|. \quad (7)$$

Again it is the square of (6) which is used in practice rather than (6) itself.

2.2. Curve Fitting

When, as is commonly the case, the mathematical form of the fitting function is immaterial to the problem, polynomials and cubic splines are to be preferred because their simplicity and ease of handling confer substantial benefits. The cubic spline is the more versatile of the two. It consists of a number of cubic polynomial segments joined end to end with continuity in first and second derivatives at the joins. The third derivative at the joins is in general discontinuous. The x-values of the joins are called knots, or, more precisely, interior knots. Their number determines the number of coefficients in the spline, just as the degree determines the number of coefficients in a polynomial.

2.2.1. Representation of polynomials

Rather than using the power-series form

$$f(x) = b_0 + b_1 x + b_2 x^2 + \dots + b_k x^k \quad (8)$$

to represent a polynomial, the routines in this chapter use the Chebyshev series form

$$f(x) = a_0 T_0(x) + a_1 T_1(x) + a_2 T_2(x) + \dots + a_k T_k(x), \quad (9)$$

where $T_i(x)$ is the Chebyshev polynomial of the first kind of degree i (see Cox and Hayes [1], page 9), and where the range of x has been normalised to run from -1 to +1. The use of either form leads theoretically to the same fitted polynomial, but in practice results may differ substantially because of the effects of rounding error. The Chebyshev form is to be preferred, since it leads to much better accuracy in general, both in the computation of the coefficients and in the subsequent evaluation of the fitted polynomial at specified points. This form also has other advantages: for example, since the later terms in (9) generally decrease much more rapidly from left to right than do those in (8), the situation is more often encountered where the last terms are negligible and it is obvious that the degree of

the polynomial can be reduced (note that on the interval $-1 \leq x \leq 1$ for all i , $T_i(x)$ attains the value unity but never exceeds it, so that the coefficient a_i gives directly the maximum value of the term containing it).

2.2.2. Representation of cubic splines

A cubic spline is represented in the form

$$f(x) = c_1 N_1(x) + c_2 N_2(x) + \dots + c_p N_p(x), \quad (10)$$

where $N_i(x)$, for $i=1,2,\dots,p$, is a normalised cubic B-spline (see Hayes [2]). This form, also, has advantages of computational speed and accuracy over alternative representations.

2.3. Surface Fitting

There are now two independent variables, and we shall denote these by x and y . The dependent variable, which was denoted by y in the curve-fitting case, will now be denoted by f . (This is a rather different notation from that indicated for the general-dimensional problem in the first paragraph of Section 2.1, but it has some advantages in presentation.)

Again, in the absence of contrary indications in the particular application being considered, polynomials and splines are the approximating functions most commonly used. Only splines are used by the surface-fitting routines in this chapter.

2.3.1. Bicubic splines: definition and representation

The bicubic spline is defined over a rectangle R in the (x,y) plane, the sides of R being parallel to the x - and y -axes. R is divided into rectangular panels, again by lines parallel to the axes. Over each panel the bicubic spline is a bicubic polynomial, that is it takes the form

$$\sum_{i=0}^3 \sum_{j=0}^3 a_{ij} x^i y^j. \quad (13)$$

Each of these polynomials joins the polynomials in adjacent panels with continuity up to the second derivative. The constant x -values of the dividing lines parallel to the y -axis form the

set of interior knots for the variable x , corresponding precisely to the set of interior knots of a cubic spline. Similarly, the constant y -values of dividing lines parallel to the x -axis form the set of interior knots for the variable y . Instead of representing the bicubic spline in terms of the above set of bicubic polynomials, however, it is represented, for the sake of computational speed and accuracy, in the form

$$f(x,y) = \sum_{i=1}^p \sum_{j=1}^q c_{ij} M_i(x) N_j(y), \quad (14)$$

where $M_i(x)$, for $i=1,2,\dots,p$, and $N_j(y)$, for $j=1,2,\dots,q$, are normalised B-splines (see Hayes and Halliday [4] for further details of bicubic splines and Hayes [2] for normalised B-splines).

2.4. General Linear and Nonlinear Fitting Functions

We have indicated earlier that, unless the data-fitting application under consideration specifically requires some other type of fitting function, a polynomial or a spline is usually to be preferred. Special routines for these functions, in one and in two variables, are provided in this chapter. When the application does specify some other fitting function, however, it may be treated by a routine which deals with a general linear function, or by one for a general nonlinear function, depending on whether the coefficients in the given function occur linearly or nonlinearly.

The general linear fitting function can be written in the form

$$f(x) = c_1(\phi_1(x)) + c_2(\phi_2(x)) + \dots + c_p(\phi_p(x)), \quad (15)$$

where x is a vector of one or more independent variables, and the ϕ_i are any given functions of these variables (though they must be linearly independent of one another if there is to be the possibility of a unique solution to the fitting problem). This is not intended to imply that each ϕ_i is necessarily a function of all the variables: we may have, for example, that each ϕ_i is a function of a different single variable, and even that one of the ϕ_i is a constant. All that is required is that a value

of each $(\phi)_i(x)$ can be computed when a value of each independent variable is given.

When the fitting function $f(x)$ is not linear in its coefficients, no more specific representation is available in general than $f(x)$ itself. However, we shall find it helpful later on to indicate the fact that $f(x)$ contains a number of coefficients (to be determined by the fitting process) by using instead the notation $f(x;c)$, where c denotes the vector of coefficients. An example of a nonlinear fitting function is

$$f(x;c) = c_1 + c_2 \exp(-c_4 x) + c_3 \exp(-c_5 x), \quad (16)$$

which is in one variable and contains five coefficients. Note that here, as elsewhere in this Chapter Introduction, we use the term 'coefficients' to include all the quantities whose values are to be determined by the fitting process, not just those which occur linearly. We may observe that it is only the presence of the coefficients c_4 and c_5 which makes the form (16) nonlinear.

If the values of these two coefficients were known beforehand, (16) would instead be a linear function which, in terms of the general linear form (15), has $p=3$ and

$$(\phi)_1(x) = 1, \quad (\phi)_2(x) = \exp(-c_4 x), \quad \text{and} \quad (\phi)_3(x) = \exp(-c_5 x).$$

We may note also that polynomials and splines, such as (9) and (14), are themselves linear in their coefficients. Thus if, when fitting with these functions, a suitable special routine is not available (as when more than two independent variables are involved or when fitting in the l_1 norm), it is appropriate to

use a routine designed for a general linear function.

2.5. Constrained Problems

So far, we have considered only fitting processes in which the values of the coefficients in the fitting function are determined by an unconstrained minimization of a particular norm. Some fitting problems, however, require that further restrictions be placed on the determination of the coefficient values. Sometimes these restrictions are contained explicitly in the formulation of the problem in the form of equalities or inequalities which the coefficients, or some function of them, must satisfy. For example, if the fitting function contains a term $A \exp(-kx)$, it may be required that $k \geq 0$. Often, however, the equality or

inequality constraints relate to the value of the fitting function or its derivatives at specified values of the independent variable(s), but these too can be expressed in terms of the coefficients of the fitting function, and it is appropriate to do this if a general linear or nonlinear routine is being used. For example, if the fitting function is that given in (10), the requirement that the first derivative of the function at $x=x_0$ be non-negative can be expressed as

$$c_{11} N'_0(x) + c_{22} N'_0(x) + \dots + c_{pp} N'_0(x) \geq 0, \quad (17)$$

where the prime denotes differentiation with respect to x and each derivative is evaluated at $x=x_0$. On the other hand, if the requirement had been that the derivative at $x=x_0$ be exactly zero, the inequality sign in (17) would be replaced by an equality.

Routines which provide a facility for minimizing the appropriate norm subject to such constraints are discussed in Section 3.6.

3. Recommendations on Choice and Use of Routines

3.1. General

The choice of a routine to treat a particular fitting problem will depend first of all on the fitting function and the norm to be used. Unless there is good reason to the contrary, the fitting

function should be a polynomial or a cubic spline (in the appropriate number of variables) and the norm should be the l_2 norm (leading to the least-squares fit). If some other function is to be used, the choice of routine will depend on whether the function is nonlinear (in which case see Section 3.5.2) or linear in its coefficients (see Section 3.5.1), and, in the latter case, on whether the l_1 or l_2 norm is to be used. The latter section is appropriate for polynomials and splines, too, if the l_1 norm is preferred.

In the case of a polynomial or cubic spline, if there is only one independent variable, the user should choose a spline (Section 3.3) when the curve represented by the data is of complicated form, perhaps with several peaks and troughs. When the curve is of simple form, first try a polynomial (see Section 3.2) of low degree, say up to degree 5 or 6, and then a spline if the polynomial fails to provide a satisfactory fit. (Of course, if third-derivative discontinuities are unacceptable to the user, a polynomial is the only choice.) If the problem is one of surface fitting, one of the spline routines should be used (Section 3.4). If the problem has more than two independent variables, it may be treated by the general linear routine in Section 3.5.1, again using a polynomial in the first instance.

Another factor which affects the choice of routine is the presence of constraints, as previously discussed in Section 2.5. Indeed this factor is likely to be overriding at present, because of the limited number of routines which have the necessary facility. See Section 3.6.

3.1.1. Data considerations

A satisfactory fit cannot be expected by any means if the number and arrangement of the data points do not adequately represent the character of the underlying relationship: sharp changes in behaviour, in particular, such as sharp peaks, should be well covered. Data points should extend over the whole range of interest of the independent variable(s): extrapolation outside the data ranges is most unwise. Then, with polynomials, it is advantageous to have additional points near the ends of the ranges, to counteract the tendency of polynomials to develop fluctuations in these regions. When, with polynomial curves, the user can precisely choose the x-values of the data, the special points defined in Section 3.2.2 should be selected. With splines the choice is less critical as long as the character of the relationship is adequately represented. All fits should be tested graphically before accepting them as satisfactory.

For this purpose it should be noted that it is not sufficient to plot the values of the fitted function only at the data values of the independent variable(s); at the least, its values at a similar number of intermediate points should also be plotted, as unwanted fluctuations may otherwise go undetected. Such fluctuations are the less likely to occur the lower the number of coefficients chosen in the fitting function. No firm guide can be given, but as a rough rule, at least initially, the number of coefficients should not exceed half the number of data points (points with equal or nearly equal values of the independent variable, or both independent variables in surface fitting, counting as a single point for this purpose). However, the situation may be such, particularly with a small number of data points, that a satisfactorily close fit to the data cannot be achieved without unwanted fluctuations occurring. In such cases, it is often possible to improve the situation by a transformation of one or more of the variables, as discussed in the next paragraph: otherwise it will be necessary to provide extra data points. Further advice on curve fitting is given in Cox and Hayes [1] and, for polynomials only, in Hayes [3] of Section 2.7. Much of the advice applies also to surface fitting; see also the Routine Documents.

3.1.2. Transformation of variables

Before starting the fitting, consideration should be given to the choice of a good form in which to deal with each of the variables: often it will be satisfactory to use the variables as they stand, but sometimes the use of the logarithm, square root, or some other function of a variable will lead to a better-behaved relationship. This question is customarily taken into account in preparing graphs and tables of a relationship and the same considerations apply when curve or surface fitting. The practical context will often give a guide. In general, it is best to avoid having to deal with a relationship whose behaviour in one region is radically different from that in another. A steep rise at the left-hand end of a curve, for example, can often best be treated by curve fitting in terms of $\log(x+c)$ with some suitable value of the constant c . A case when such a transformation gave substantial benefit is discussed in Hayes [3] page 60. According to the features exhibited in any particular case, transformation of either dependent variable or independent variable(s) or both may be beneficial. When there is a choice it is usually better to transform the independent variable(s): if the dependent variable is transformed, the weights attached to the data points must be adjusted. Thus (denoting the dependent variable by y , as in the notation for curves) if the y to be

r
fitted have been obtained by a transformation $y=g(Y)$ from

original data values Y_r , with weights W_r , for $r=1,2,\dots,m$, we must take

$$w_r = W_r / (dy/dY_r), \quad (18)$$

where the derivative is evaluated at Y_r . Strictly, the transformation of Y and the adjustment of weights are valid only when the data errors in the Y_r are small compared with the range spanned by the Y_r , but this is usually the case.

3.2. Polynomial Curves

3.2.1. Least-squares polynomials: arbitrary data points

E02ADF fits to arbitrary data points, with arbitrary weights, polynomials of all degrees up to a maximum degree k , which is at choice. If the user is seeking only a low degree polynomial, up to degree 5 or 6 say, $k=10$ is an appropriate value, providing there are about 20 data points or more. To assist in deciding the degree of polynomial which satisfactorily fits the data, the routine provides the root-mean-square-residual s_i for all degrees $i=1,2,\dots,k$. In a satisfactory case, these s_i will decrease steadily as i increases and then settle down to a fairly constant value, as shown in the example

i	s_i
0	3.5215
1	0.7708
2	0.1861
3	0.0820
4	0.0554
5	0.0251
6	0.0264
7	0.0280

8 0.0277

9 0.0297

10 0.0271

If the s_i values settle down in this way, it indicates that the closest polynomial approximation justified by the data has been achieved. The degree which first gives the approximately constant value of s_i (degree 5 in the example) is the appropriate degree to select. (Users who are prepared to accept a fit higher than sixth degree, should simply find a high enough value of k to enable the type of behaviour indicated by the example to be detected: thus they should seek values of k for which at least 4 or 5 consecutive values of s_i are approximately the same.) If the degree were allowed to go high enough, s_i would, in most cases, eventually start to decrease again, indicating that the data points are being fitted too closely and that undesirable fluctuations are developing between the points. In some cases, particularly with a small number of data points, this final decrease is not distinguishable from the initial decrease in s_i .

In such cases, users may seek an acceptable fit by examining the graphs of several of the polynomials obtained. Failing this, they may (a) seek a transformation of variables which improves the behaviour, (b) try fitting a spline, or (c) provide more data points. If data can be provided simply by drawing an approximating curve by hand and reading points from it, use the points discussed in Section 3.2.2.

3.2.2. Least-squares polynomials: selected data points

When users are at liberty to choose the x -values of data points, such as when the points are taken from a graph, it is most advantageous when fitting with polynomials to use the values $x_r = \cos((\pi)r/n)$, for $r=0,1,\dots,n$ for some value of n , a suitable value for which is discussed at the end of this section. Note that these x_r relate to the variable x after it has been normalised so that its range of interest is -1 to $+1$. E02ADF may then be used as in Section 3.2.1 to seek a satisfactory fit.

3.3. Cubic Spline Curves

3.3.1. Least-squares cubic splines

E02BAF fits to arbitrary data points, with arbitrary weights, a cubic spline with interior knots specified by the user. The choice of these knots so as to give an acceptable fit must largely be a matter of trial and error, though with a little experience a satisfactory choice can often be made after one or two trials. It is usually best to start with a small number of knots (too many will result in unwanted fluctuations in the fit, or even in there being no unique solution) and, examining the fit graphically at each stage, to add a few knots at a time at places where the fit is particularly poor. Moving the existing knots towards these places will also often improve the fit. In regions where the behaviour of the curve underlying the data is changing rapidly, closer knots will be needed than elsewhere. Otherwise, positioning is not usually very critical and equally-spaced knots are often satisfactory. See also the next section, however.

A useful feature of the routine is that it can be used in applications which require the continuity to be less than the normal continuity of the cubic spline. For example, the fit may be required to have a discontinuous slope at some point in the range. This can be achieved by placing three coincident knots at the given point. Similarly a discontinuity in the second derivative at a point can be achieved by placing two knots there. Analogy with these discontinuous cases can provide guidance in more usual cases: for example, just as three coincident knots can produce a discontinuity in slope, so three close knots can produce a rapid change in slope. The closer the knots are, the more rapid can the change be.

Figure 1

Please see figure in printed Reference Manual

An example set of data is given in Figure 1. It is a rather tricky set, because of the scarcity of data on the right, but it will serve to illustrate some of the above points and to show some of the dangers to be avoided. Three interior knots (indicated by the vertical lines at the top of the diagram) are chosen as a start. We see that the resulting curve is not steep enough in the middle and fluctuates at both ends, severely on the right. The spline is unable to cope with the shape and more knots are needed.

In Figure 2, three knots have been added in the centre, where the data shows a rapid change in behaviour, and one further out at each end, where the fit is poor. The fit is still poor, so a further knot is added in this region and, in Figure 3, disaster ensues in rather spectacular fashion.

Figure 2

Please see figure in printed Reference Manual

Figure 3

Please see figure in printed Reference Manual

The reason is that, at the right-hand end, the fits in Figure 1 and Figure 2 have been interpreted as poor simply because of the fluctuations about the curve underlying the data (or what it is naturally assumed to be). But the fitting process knows only about the data and nothing else about the underlying curve, so it is important to consider only closeness to the data when deciding goodness of fit.

Thus, in Figure 1, the curve fits the last two data points quite well compared with the fit elsewhere, so no knot should have been added in this region. In Figure 2, the curve goes exactly through the last two points, so a further knot is certainly not needed here.

Figure 4

Please see figure in printed Reference Manual

Figure 4 shows what can be achieved without the extra knot on each of the flat regions. Remembering that within each knot interval the spline is a cubic polynomial, there is really no need to have more than one knot interval covering each flat region.

What we have, in fact, in Figure 2 and Figure 3 is a case of too many knots (so too many coefficients in the spline equation) for the number of data points. The warning in the second paragraph of Section 2.1 was that the fit will then be too close to the data, tending to have unwanted fluctuations between the data points. The warning applies locally for splines, in the sense that, in localities where there are plenty of data points, there can be a lot of knots, as long as there are few knots where there are few points, especially near the ends of the interval. In the present example, with so few data points on the right, just the one extra knot in Figure 2 is too many! The signs are clearly present, with the last two points fitted exactly (at least to the graphical accuracy and actually much closer than that) and fluctuations within the last two knot-intervals (cf. Figure 1, where only the final point is fitted exactly and one of the wobbles spans several data points).

The situation in Figure 3 is different. The fit, if computed exactly, would still pass through the last two data points, with even more violent fluctuations. However, the problem has become

so ill-conditioned that all accuracy has been lost. Indeed, if the last interior knot were moved a tiny amount to the right, there would be no unique solution and an error message would have been caused. Near-singularity is, sadly, not picked up by the routine, but can be spotted readily in a graph, as Figure 3. B-spline coefficients becoming large, with alternating signs, is another indication. However, it is better to avoid such situations, firstly by providing, whenever possible, data adequately covering the range of interest, and secondly by placing knots only where there is a reasonable amount of data.

The example here could, in fact, have utilised from the start the observation made in the second paragraph of this section, that three close knots can produce a rapid change in slope. The example has two such rapid changes and so requires two sets of three close knots (in fact, the two sets can be so close that one knot can serve in both sets, so only five knots prove sufficient in Figure 4). It should be noted, however, that the rapid turn occurs within the range spanned by the three knots. This is the reason that the six knots in Figure 2 are not satisfactory as they do not quite span the two turns.

Some more examples to illustrate the choice of knots are given in Cox and Hayes [1].

3.3.2. Automatic fitting with cubic splines

E02BEF also fits cubic splines to arbitrary data points with arbitrary weights but itself chooses the number and positions of the knots. The user has to supply only a threshold for the sum of squares of residuals. The routine first builds up a knot set by a series of trial fits in the l_1 norm. Then, with the knot set

2

decided, the final spline is computed to minimize a certain smoothing measure subject to satisfaction of the chosen threshold. Thus it is easier to use than E02BAF (see previous section), requiring only some experimentation with this threshold. It should therefore be first choice unless the user has a preference for the ordinary least-squares fit or, for example, wishes to experiment with knot positions, trying to keep their number down (E02BEF aims only to be reasonably frugal with knots).

3.4. Spline Surfaces

3.4.1. Least-squares bicubic splines

E02DAF fits to arbitrary data points, with arbitrary weights, a bicubic spline with its two sets of interior knots specified by the user. For choosing these knots, the advice given for cubic

splines, in Section 3.3.1 above, applies here too. (See also the next section, however.) If changes in the behaviour of the surface underlying the data are more marked in the direction of one variable than of the other, more knots will be needed for the former variable than the latter. Note also that, in the surface case, the reduction in continuity caused by coincident knots will extend across the whole spline surface: for example, if three knots associated with the variable x are chosen to coincide at a value L , the spline surface will have a discontinuous slope across the whole extent of the line $x=L$.

With some sets of data and some choices of knots, the least-squares bicubic spline will not be unique. This will not occur, with a reasonable choice of knots, if the rectangle R is well covered with data points: here R is defined as the smallest rectangle in the (x,y) plane, with sides parallel to the axes, which contains all the data points. Where the least-squares solution is not unique, the minimal least-squares solution is computed, namely that least-squares solution which has the smallest value of the sum of squares of the B-spline coefficients c_{ij} (see the end of Section 2.3.2 above). This choice of least-squares solution tends to minimize the risk of unwanted fluctuations in the fit. The fit will not be reliable, however, in regions where there are few or no data points.

3.4.2. Automatic fitting with bicubic splines

E02DDF also fits bicubic splines to arbitrary data points with arbitrary weights but chooses the knot sets itself. The user has to supply only a threshold for the sum of squares of residuals. Just like the automatic curve E02BEF (Section 3.3.2), E02DDF then builds up the knot sets and finally fits a spline minimizing a smoothing measure subject to satisfaction of the threshold. Again, this easier to use routine is normally to be preferred, at least in the first instance.

E02DCF is a very similar routine to E02DDF but deals with data points of equal weight which lie on a rectangular mesh in the (x,y) plane. This kind of data allows a very much faster computation and so is to be preferred when applicable. Substantial departures from equal weighting can be ignored if the user is not concerned with statistical questions, though the quality of the fit will suffer if this is taken too far. In such cases, the user should revert to E02DDF.

3.5. General Linear and Nonlinear Fitting Functions

3.5.1. General linear functions

For the general linear function (15), routines are available for fitting in the l_1 and l_2 norms. The least-squares routines (which are to be preferred unless there is good reason to use another norm -- see Section 2.1.1) are in Chapter F04. The l_1 routine is E02GAF.

All the above routines are essentially linear algebra routines, and in considering their use we need to view the fitting process in a slightly different way from hitherto. Taking y to be the dependent variable and x the vector of independent variables, we have, as for equation (1) but with each x now a vector,

$$(\epsilon)_r = y_r - f(x)_r \quad r=1,2,\dots,m.$$

Substituting for $f(x)$ the general linear form (15), we can write this as

$$c_1(\phi)_1(x)_r + c_2(\phi)_2(x)_r + \dots + c_p(\phi)_p(x)_r = y_r - (\epsilon)_r, \quad r=1,2,\dots,m \quad (19)$$

Thus we have a system of linear equations in the coefficients c_j . Usually, in writing these equations, the $(\epsilon)_r$ are omitted and simply taken as implied. The system of equations is then described as an overdetermined system (since we must have $m \geq p$ if there is to be the possibility of a unique solution to our fitting problem), and the fitting process of computing the c_j to minimize one or other of the norms (2), (3) and (4) can be described, in relation to the system of equations, as solving the overdetermined system in that particular norm. In matrix notation, the system can be written as

$$(\Phi)c = y, \quad (20)$$

where (Φ) is the m by p matrix whose element in row r and column j is $(\phi)_j(x)_r$, for $r=1,2,\dots,m$; $j=1,2,\dots,p$. The vectors c and y respectively contain the coefficients c_j and the data values y_r .

The routines, however, use the standard notation of linear algebra, the overdetermined system of equations being denoted by

$$Ax=b \quad (21)$$

The correspondence between this notation and that which we have used for the data-fitting problem (equation (20)) is therefore given by

$$A=(\Phi), \quad x=c \quad b=y \quad (22)$$

Note that the norms used by these routines are the unweighted norms (2) and (3). If the user wishes to apply weights to the data points, that is to use the norms (5) or (6), the equivalences (22) should be replaced by

$$A=D(\Phi), \quad x=c \quad b=Dy$$

where D is a diagonal matrix with w_r as the r th diagonal element.

Here w_r , for $r=1,2,\dots,m$, is the weight of the r th data point as defined in Section 2.1.2.

3.5.2. Nonlinear functions

Routines for fitting with a nonlinear function in the l_2 norm are provided in Chapter E04, and that chapter's Introduction should be consulted for the appropriate choice of routine. Again, however, the notation adopted is different from that we have used for data fitting. In the latter, we denote the fitting function by $f(x;c)$, where x is the vector of independent variables and c is the vector of coefficients, whose values are to be determined. The squared l_2 norm, to be minimized with respect to the elements of c , is then

$$\begin{aligned} & \sum_{r=1}^m w_r [y_r - f(x_r; c)]^2 \end{aligned} \quad (23)$$

where y_r is the r th data value of the dependent variable, x_r is the vector containing the r th values of the independent variables, and w_r is the corresponding weight as defined in Section 2.1.2.

On the other hand, in the nonlinear least-squares routines of Chapter E04, the function to be minimized is denoted by

$$f(x) = \sum_{i=1}^m f_i(x), \quad (24)$$

the minimization being carried out with respect to the elements of the vector x . The correspondence between the two notations is given by

$x=c$ and

$$f_i(x) = w_r [y_r - f(x; c)], \quad i=r=1, 2, \dots, m.$$

Note especially that the vector x of variables of the nonlinear least-squares routines is the vector c of coefficients of the data-fitting problem, and in particular that, if the selected routine requires derivatives of the $f_i(x)$ to be provided, these

are derivatives of $w_r [y_r - f(x; c)]$ with respect to the coefficients of the data-fitting problem.

3.6. Constraints

At present, there are only a limited number of routines which fit subject to constraints. Chapter E04 contains a routine, E04UCF, which can be used for fitting with a nonlinear function in the l_2 norm subject to equality or inequality constraints. This routine, unlike those in that chapter suited to the unconstrained case, is not designed specifically for minimizing functions which are sums of squares, and so the function (23) has to be treated as a general nonlinear function. The E04 Chapter Introduction should be consulted.

The remaining constraint routine relates to fitting with polynomials in the l_2 norm. E02AGF deals with polynomial curves

and allows precise values of the fitting function and (if required) all its derivatives up to a given order to be prescribed at one or more values of the independent variable.

3.7. Evaluation, Differentiation and Integration

Routines are available to evaluate, differentiate and integrate polynomials in Chebyshev-series form and cubic or bicubic splines in B-spline form. These polynomials and splines may have been produced by the various fitting routines or, in the case of polynomials, from prior calls of the differentiation and integration routines themselves.

E02AEF and E02AKF evaluate polynomial curves: the latter has a longer parameter list but does not require the user to normalise the values of the independent variable and can accept coefficients which are not stored in contiguous locations. E02BBF evaluates cubic spline curves, and E02DEF and E02DFF bicubic spline surfaces.

Differentiation and integration of polynomial curves are carried out by E02AHF and E02AJF respectively. The results are provided in Chebyshev-series form and so repeated differentiation and integration are catered for. Values of the derivative or integral can then be computed using the appropriate evaluation routine.

For splines the differentiation and integration routines provided are of a different nature from those for polynomials. E02BCF provides values of a cubic spline curve and its first three derivatives (the rest, of course, are zero) at a given value of x spline over its whole range. These routines can also be applied to surfaces of the form (14). For example, if, for each value of j in turn, the coefficients c_{ij} , for $i=1,2,\dots,p$ are supplied to

E02BCF with $x=x_0$ and on each occasion we select from the output the value of the second derivative, d_j say, and if the whole set of d_j are then supplied to the same routine with $x=y_0$, the output will contain all the values at (x_0, y_0) of

$$\frac{\partial^2 f}{\partial x^2} \quad \text{and} \quad \frac{\partial^{r+2} f}{\partial x^2 \partial y^r}, \quad r=1,2,3.$$

Equally, if after each of the first p calls of E02BCF we had selected the function value (E02BBF would also provide this) instead of the second derivative and we had supplied these values to E02BDF, the result obtained would have been the value of

$$\frac{B}{}$$

$$\int_A^B f(x,y)dy,$$

where A and B are the end-points of the y interval over which the spline was defined.

E02 -- Curve and Surface Fitting E02ADF
 E02ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
 your implementation to check implementation-dependent details.
 The symbol (*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

1. Purpose

E02ADF computes weighted least-squares polynomial approximations to an arbitrary set of data points.

2. Specification

```

      SUBROUTINE E02ADF (M, KPLUS1, NROWS, X, Y, W, WORK1,
1      WORK2, A, S, IFAIL)
      INTEGER          M, KPLUS1, NROWS, IFAIL
      DOUBLE PRECISION X(M), Y(M), W(M), WORK1(3*M), WORK2
1      (2*KPLUS1), A(NROWS,KPLUS1), S(KPLUS1)

```

3. Description

This routine determines least-squares polynomial approximations of degrees $0, 1, \dots, k$ to the set of data points (x_r, y_r) with

weights w_r , for $r=1, 2, \dots, m$.

The approximation of degree i has the property that it minimizes (σ_i) the sum of squares of the weighted residuals (ϵ_r) , where

$$(\epsilon_r) = w_r (y_r - f_r)$$

and f_r is the value of the polynomial of degree i at the r th data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument x . This argument lies in the range -1 to $+1$ and is related to the original variable x by the linear transformation

$$x = \frac{(2x_{\max} - x_{\min})}{(x_{\max} - x_{\min})}.$$

Here $x_{\max}$ and $x_{\min}$ are respectively the largest and smallest

values of x_r . The polynomial approximation of degree i is represented as

$$-a_{i+1,1} T_0(x) + a_{i+1,2} T_1(x) + a_{i+1,3} T_2(x) + \dots + a_{i+1,i+1} T_i(x),$$

where $T_j(x)$ is the Chebyshev polynomial of the first kind of degree j with argument (x) .

For $i=0,1,\dots,k$, the routine produces the values of $a_{i+1,j+1}$, for $j=0,1,\dots,i$, together with the value of the root mean square

$$\text{residual } s_i = \frac{1}{\sqrt{i}} \sqrt{\sum_{j=0}^i (a_{i+1,j+1})^2}.$$

In the case $m=i+1$ the routine sets the value of s_i to zero.

The method employed is due to Forsythe [4] and is based upon the generation of a set of polynomials orthogonal with respect to summation over the normalised data set. The extensions due to Clenshaw [1] to represent these polynomials as well as the approximating polynomials in their Chebyshev-series forms are incorporated. The modifications suggested by Reinsch and Gentleman (see [5]) to the method originally employed by Clenshaw for evaluating the orthogonal polynomials from their Chebyshev-series representations are used to give greater numerical stability.

For further details of the algorithm and its use see Cox [2] and [3].

Subsequent evaluation of the Chebyshev-series representations of the polynomial approximations should be carried out using E02AEF.

5. Parameters

- 1: M -- INTEGER Input
On entry: the number m of data points. Constraint: $M \geq MDIST$, where MDIST is the number of distinct x values in the data.
- 2: KPLUS1 -- INTEGER Input
On entry: k+1, where k is the maximum degree required.
Constraint: $0 < KPLUS1 \leq MDIST$, where MDIST is the number of distinct x values in the data.
- 3: NROWS -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which E02ADF is called.
Constraint: $NROWS \geq KPLUS1$.
- 4: X(M) -- DOUBLE PRECISION array Input
On entry: the values x_r of the independent variable, for $r=1,2,\dots,m$. Constraint: the values must be supplied in non-decreasing order with $X(M) > X(1)$.
- 5: Y(M) -- DOUBLE PRECISION array Input
On entry: the values y_r of the dependent variable, for $r=1,2,\dots,m$.
- 6: W(M) -- DOUBLE PRECISION array Input

On entry: the set of weights, w_r , for $r=1,2,\dots,m$. For advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint: $W(r) > 0.0$, for $r=1,2,\dots,m$.

7: WORK1(3*M) -- DOUBLE PRECISION array Workspace
 8: WORK2(2*KPLUS1) -- DOUBLE PRECISION array Workspace
 9: A(NROWS,KPLUS1) -- DOUBLE PRECISION array Output

On exit: the coefficients of $T_j(x)$ in the approximating polynomial of degree i . $A(i+1,j+1)$ contains the coefficient $a_{i+1,j+1}$, for $i=0,1,\dots,k$; $j=0,1,\dots,i$.

10: S(KPLUS1) -- DOUBLE PRECISION array Output
 On exit: $S(i+1)$ contains the root mean square residual s_i , for $i=0,1,\dots,k$, as described in Section 3. For the interpretation of the values of the s_i and their use in selecting an appropriate degree, see Section 3.1 of the Chapter Introduction.

11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 The weights are not all strictly positive.

IFAIL= 2
 The values of $X(r)$, for $r=1,2,\dots,M$ are not in non-decreasing order.

IFAIL= 3
 All $X(r)$ have the same value: thus the normalisation of X is not possible.

IFAIL= 4

On entry KPLUS1 < 1 (so the maximum degree required is negative)

or KPLUS1 > MDIST, where MDIST is the number of distinct x values in the data (so there cannot be a unique solution for degree $k = \text{KPLUS1} - 1$).

IFAIL= 5

NROWS < KPLUS1.

7. Accuracy

No error analysis for the method has been published. Practical experience with the method, however, is generally extremely satisfactory.

8. Further Comments

The time taken by the routine is approximately proportional to $m(k+1)(k+11)$.

The approximating polynomials may exhibit undesirable oscillations (particularly near the ends of the range) if the maximum degree k exceeds a critical value which depends on the number of data points m and their relative positions. As a rough guide, for equally-spaced data, this critical value is about

$2\sqrt{m}$. For further details see Hayes [6] page 60.

9. Example

Determine weighted least-squares polynomial approximations of degrees 0, 1, 2 and 3 to a set of 11 prescribed data points. For the approximation of degree 3, tabulate the data and the corresponding values of the approximating polynomial, together with the residual errors, and also the values of the approximating polynomial at points half-way between each pair of adjacent data points.

The example program supplied is written in a general form that will enable polynomial approximations of degrees 0, 1, ..., k to be obtained to m data points, with arbitrary positive weights, and the approximation of degree k to be tabulated. E02AEF is used to evaluate the approximating polynomial. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

Library software and should be available on-line.

%%%

E02 -- Curve and Surface Fitting E02AEF
 E02AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AEF evaluates a polynomial from its Chebyshev-series representation.

2. Specification

```
SUBROUTINE E02AEF (NPLUS1, A, XCAP, P, IFAIL)
  INTEGER          NPLUS1, IFAIL
  DOUBLE PRECISION A(NPLUS1), XCAP, P
```

3. Description

This routine evaluates the polynomial

$$-a_1 T_0(x) + a_2 T_1(x) + a_3 T_2(x) + \dots + a_{n+1} T_n(x)$$

for any value of x satisfying $-1 \leq x \leq 1$. Here $T_j(x)$ denotes the Chebyshev polynomial of the first kind of degree j with argument

x . The value of n is prescribed by the user.

In practice, the variable x will usually have been obtained from an original variable x , where $x_{\min} \leq x \leq x_{\max}$ and

$$x = \frac{((x_{\min} - x_{\max}) - (x_{\min} - x_{\max}))}{(x_{\min} - x_{\max})}$$

max min

Note that this form of the transformation should be used computationally rather than the mathematical equivalent

$$x = \frac{(2x_{\min} - x_{\max})}{(x_{\max} - x_{\min})}$$

since the former guarantees that the computed value of x differs from its true value by at most $4(\text{epsilon})$, where (epsilon) is the machine precision, whereas the latter has no such guarantee.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications to give greater numerical stability due to Reinsch and Gentleman (see [4]).

For further details of the algorithm and its use see Cox [2] and [3].

4. References

- [2] Cox M G (1974) A Data-fitting Package for the Non-specialist User. Software for Numerical Mathematics. (ed D J Evans) Academic Press.
- [3] Cox M G and Hayes J G (1973) Curve fitting: a guide and suite of algorithms for the non-specialist user. Report NAC26. National Physical Laboratory.
- [4] Gentlemen W M (1969) An Error Analysis of Goertzel's (Watt's) Method for Computing Fourier Coefficients. Comput. J. 12 160--165.

5. Parameters

- 1: NPLUS1 -- INTEGER Input
On entry: the number $n+1$ of terms in the series (one greater than the degree of the polynomial). Constraint: NPLUS1 ≥ 1 .
- 2: A(NPLUS1) -- DOUBLE PRECISION array Input
On entry: A(i) must be set to the value of the i th

coefficient in the series, for $i=1,2,\dots,n+1$.

3: XCAP -- DOUBLE PRECISION Input

On entry: x , the argument at which the polynomial is to be evaluated. It should lie in the range -1 to $+1$, but a value just outside this range is permitted (see Section 6) to allow for possible rounding errors committed in the

transformation from x to x discussed in Section 3. Provided the recommended form of the transformation is used, a successful exit is thus assured whenever the value of x lies in the range $x_{\min}$ to $x_{\max}$.

4: P -- DOUBLE PRECISION Output
On exit: the value of the polynomial.

5: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1 . For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

$\text{ABS}(\text{XCAP}) > 1.0 + 4(\text{epsilon})$, where (epsilon) is the machine precision. In this case the value of P is set arbitrarily to zero.

IFAIL= 2

On entry $\text{NPLUS1} < 1$.

7. Accuracy

The rounding errors committed are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients $a_i + (\delta_i)a_i$. The ratio of the sum of the absolute values of the $(\delta_i)a_i$ to the sum of the absolute values of the a_i is less than a small multiple of $(n+1)$ times machine

precision.

8. Further Comments

The time taken by the routine is approximately proportional to $n+1$.

It is expected that a common use of E02AEF will be the evaluation of the polynomial approximations produced by E02ADF and E02AFF(*)

9. Example

Evaluate at 11 equally-spaced points in the interval $-1 \leq x \leq 1$ the polynomial of degree 4 with Chebyshev coefficients, 2.0, 0.5, 0.25, 0.125, 0.0625.

The example program is written in a general form that will enable a polynomial of degree n in its Chebyshev-series form to be

evaluated at m equally-spaced points in the interval $-1 \leq x \leq 1$. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02AGF
E02AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AGF computes constrained weighted least-squares polynomial approximations in Chebyshev-series form to an arbitrary set of data points. The values of the approximations and any number of their derivatives can be specified at selected points.

2. Specification

SUBROUTINE E02AGF (M, KPLUS1, NROWS, XMIN, XMAX, X, Y, W,

```

1          MF, XF, YF, LYF, IP, A, S, NP1, WRK,
2          LWRK, IWRK, LIWRK, IFAIL)
  INTEGER      M, KPLUS1, NROWS, MF, LYF, IP(MF), NP1,
1          LWRK, IWRK(LIWRK), LIWRK, IFAIL
  DOUBLE PRECISION XMIN, XMAX, X(M), Y(M), W(M), XF(MF), YF
1          (LYF), A(NROWS,KPLUS1), S(KPLUS1), WRK
2          (LWRK)

```

3. Description

This routine determines least-squares polynomial approximations of degrees up to k to the set of data points (x_r, y_r) with weights

w_r , for $r=1,2,\dots,m$. The value of k , the maximum degree required,

is prescribed by the user. At each of the values x_r , for $r =$

$1,2,\dots,MF$, of the independent variable x , the approximations and their derivatives up to order p are constrained to have one of

the user-specified values y_s , for $s=1,2,\dots,n$, where $n=MF+ > p$

The approximation of degree i has the property that, subject to the imposed constraints, it minimizes $(\text{Sigma})_i$, the sum of the squares of the weighted residuals (epsilon) for $r=1,2,\dots,m$

where

$$(\text{epsilon})_{r,i} = w_r (y_r - f_i(x_r))$$

and $f_i(x_r)$ is the value of the polynomial approximation of degree i at the r th data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument x . This argument lies in the range -1 to $+1$ and is related to the original variable x by the linear transformation

$$x = \frac{2x_{\max} - (x_{\min} + x_{\max})}{x_{\max} - x_{\min}}$$

$$\frac{(x_{\max} - x_{\min})}{2}$$

where $x_{\min}$ and $x_{\max}$, specified by the user, are respectively the lower and upper end-points of the interval of x over which the polynomials are to be defined.

The polynomial approximation of degree i can be written as

$$-a_{i,0} + a_{i,1} T_1(x) + \dots + a_{i,j} T_j(x) + \dots + a_{i,i} T_i(x)$$

where $T_j(x)$ is the Chebyshev polynomial of the first kind of degree j with argument x .

For $i=n, n+1, \dots, k$, the routine produces the values of the coefficients $a_{i,j}$, for $j=0, 1, \dots, i$, together

with the value of the root mean square residual, S_i , defined as

$$S_i = \frac{1}{\sqrt{(m' + n - i - 1)}} \sqrt{\sum_{j=1}^{m'} w_j (y_j - \mu_j)^2}$$

where m' is the number of data points with non-zero weight.

Values of the approximations may subsequently be computed using E02AEF or E02AKF.

First E02AGF determines a polynomial $(\mu)(x)$, of degree $n-1$, which satisfies the given constraints, and a polynomial $(\nu)(x)$, of degree n , which has value (or derivative) zero wherever a constrained value (or derivative) is specified. It then fits $y_r - (\mu)(x_r)$, for $r=1, 2, \dots, m$ with polynomials of the required

degree in x each with factor $(\nu)(x)$. Finally the coefficients of

$(\mu)(x)$ are added to the coefficients of these fits to give the coefficients of the constrained polynomial approximations to the data points (x_r, y_r) , for $r=1,2,\dots,m$. The method employed is given in Hayes [3]: it is an extension of Forsythe's orthogonal polynomials method [2] as modified by Clenshaw [1].

4. References

- [1] Clenshaw C W (1960) Curve Fitting with a Digital Computer. Comput. J. 2 170--173.

- [3] Hayes J G (1970) Curve Fitting by Polynomials in One Variable. Numerical Approximation to Functions and Data. (ed J G Hayes) Athlone Press, London.

5. Parameters

- 1: M -- INTEGER Input
On entry: the number m of data points to be fitted.
Constraint: $M \geq 1$.
- 2: KPLUS1 -- INTEGER Input
On entry: $k+1$, where k is the maximum degree required.
Constraint: $n+1 \leq KPLUS1 \leq m''+n$, where n is the total number of constraints and m'' is the number of data points with non-zero weights and distinct abscissae which do not coincide with any of the $XF(r)$.
- 3: NROWS -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which E02AGF is called.
Constraint: $NROWS \geq KPLUS1$.
- 4: XMIN -- DOUBLE PRECISION Input
- 5: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points, respectively, of the interval $[x_{\min}, x_{\max}]$. Unless there are specific reasons to the contrary, it is recommended that XMIN and XMAX be set respectively to the lowest and highest value among the x_r and $XF(r)$. This avoids the danger of extrapolation provided

there is a constraint point or data point with non-zero weight at each end-point. Constraint: $XMAX > XMIN$.

- 6: $X(M)$ -- DOUBLE PRECISION array Input
 On entry: the value x_r of the independent variable at the r th data point, for $r=1,2,\dots,m$. Constraint: the $X(r)$ must be in non-decreasing order and satisfy $XMIN \leq X(r) \leq XMAX$.
- 7: $Y(M)$ -- DOUBLE PRECISION array Input
 On entry: $Y(r)$ must contain y_r , the value of the dependent variable at the r th data point, for $r=1,2,\dots,m$.
- 8: $W(M)$ -- DOUBLE PRECISION array Input
 On entry: the weights w_r to be applied to the data points x_r , for $r=1,2,\dots,m$. For advice on the choice of weights see the Chapter Introduction. Negative weights are treated as positive. A zero weight causes the corresponding data point to be ignored. Zero weight should be given to any data point whose x and y values both coincide with those of a constraint (otherwise the denominators involved in the root-mean-square residuals s_i will be slightly in error).
- 9: MF -- INTEGER Input
 On entry: the number of values of the independent variable at which a constraint is specified. Constraint: $MF \geq 1$.
- 10: $XF(MF)$ -- DOUBLE PRECISION array Input
 On entry: the r th value of the independent variable at which a constraint is specified, for $r = 1,2,\dots,MF$. Constraint: these values need not be ordered but must be distinct and satisfy $XMIN \leq XF(r) \leq XMAX$.
- 11: $YF(LYF)$ -- DOUBLE PRECISION array Input
 On entry: the values which the approximating polynomials and their derivatives are required to take at the points specified in XF . For each value of $XF(r)$, YF contains in successive elements the required value of the approximation, its first derivative, second derivative, ..., p th derivative, for $r = 1,2,\dots,MF$. Thus the value which the k th derivative of each approximation ($k=0$ referring to the approximation itself) is required to take at the point $XF(r)$ must be contained in $YF(s)$, where
- $$s = r + k + p_1 + p_2 + \dots + p_{r-1},$$

for $k=0,1,\dots,p$ and $r = 1,2,\dots,MF$. The derivatives are
 r
 with respect to the user's variable x .

- 12: LYF -- INTEGER Input
 On entry:
 the dimension of the array YF as declared in the
 (sub)program from which E02AGF is called.
 Constraint: $LYF \geq n$, where $n = MF + p_1 + p_2 + \dots + p_{MF}$.

- 13: IP(MF) -- INTEGER array Input
 On entry: IP(r) must contain p_r , the order of the highest-
 r
 order derivative specified at XF(r), for $r = 1,2,\dots,MF$.
 $p = 0$ implies that the value of the approximation at XF(r) is
 r
 specified, but not that of any derivative. Constraint: IP(r)
 ≥ 0 , for $r=1,2,\dots,MF$.

- 14: A(NROWS,KPLUS1) -- DOUBLE PRECISION array Output
 On exit: A(i+1,j+1) contains the coefficient a_{ij} in the
 ij
 approximating polynomial of degree i , for $i=n,n+1,\dots,k$;
 $j=0,1,\dots,i$.

- 15: S(KPLUS1) -- DOUBLE PRECISION array Output
 On exit: S(i+1) contains s_i , for $i=n,n+1,\dots,k$, the root-
 i
 mean-square residual corresponding to the approximating
 polynomial of degree i . In the case where the number of data
 points with non-zero weight is equal to $k+1-n$, s_i is
 i
 indeterminate: the routine sets it to zero. For the
 interpretation of the values of s_i and their use in
 i
 selecting an appropriate degree, see Section 3.1 of the
 Chapter Introduction.

- 16: NP1 -- INTEGER Output
 On exit: $n+1$, where n is the total number of constraint
 conditions imposed: $n = MF + p_1 + p_2 + \dots + p_{MF}$.

- 17: WRK(LWRK) -- DOUBLE PRECISION array Output
 On exit: WRK contains weighted residuals of the highest
 degree of fit determined (k). The residual at x is in
 element $2(n+1)+3(m+k+1)+r$, for $r=1,2,\dots,m$. The rest of the
 array is used as workspace.

- 18: LWRK -- INTEGER Input
 On entry:
 the dimension of the array WRK as declared in the
 (sub)program from which E02AGF is called.
 Constraint: $LWRK \geq \max(4*M+3*KPLUS1, 8*n+5*IPMAX+MF+10)+2*n+2$
 , where $IPMAX = \max(IP(R))$.
- 19: IWRK(LIWRK) -- INTEGER array Workspace
- 20: LIWRK -- INTEGER Input
 On entry:
 the dimension of the array IWRK as declared in the
 (sub)program from which E02AGF is called.
 Constraint: $LIWRK \geq 2*MF+2$.
- 21: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry $M < 1$,

or $KPLUS1 < n + 1$,

or $NROWS < KPLUS1$,

or $MF < 1$,

or $LYF < n$,

or LWRK is too small (see Section 5),

or $LIWRK < 2*MF+2$.

(Here n is the total number of constraint conditions.)

IFAIL= 2

$IP(r) < 0$ for some $r = 1, 2, \dots, MF$.

IFAIL= 3

$XMIN \geq XMAX$, or $XF(r)$ is not in the interval $XMIN$ to $XMAX$
 for some $r = 1, 2, \dots, MF$, or the $XF(r)$ are not distinct.

IFAIL= 4

X(r) is not in the interval XMIN to XMAX for some
r=1,2,...,M.

IFAIL= 5

X(r) < X(r-1) for some r=2,3,...,M.

IFAIL= 6

KPLUS1>m''+n, where m'' is the number of data points with
non-zero weight and distinct abscissae which do not coincide
with any XF(r). Thus there is no unique solution.

IFAIL= 7

The polynomials (mu)(x) and/or (nu)(x) cannot be determined.
The problem supplied is too ill-conditioned. This may occur
when the constraint points are very close together, or large
in number, or when an attempt is made to constrain high-
order derivatives.

7. Accuracy

No complete error analysis exists for either the interpolating
algorithm or the approximating algorithm. However, considerable
experience with the approximating algorithm shows that it is
generally extremely satisfactory. Also the moderate number of
constraints, of low order, which are typical of data fitting
applications, are unlikely to cause difficulty with the
interpolating routine.

8. Further Comments

The time taken by the routine to form the interpolating

3

polynomial is approximately proportional to n, and that to form
the approximating polynomials is very approximately proportional
to m(k+1)(k+1-n).

To carry out a least-squares polynomial fit without constraints,
use EO2ADF. To carry out polynomial interpolation only, use
EO1AEF(*) .

9. Example

The example program reads data in the following order, using the
notation of the parameter list above:

MF

IP(i), XF(i), Y-value and derivative values (if any) at
XF(i), for i= 1,2,...,MF

```

M
X(i), Y(i), W(i), for i=1,2,...,M
k, XMIN, XMAX

```

The output is:

```

the root-mean-square residual for each degree from n to k;

the Chebyshev coefficients for the fit of degree k;

the data points, and the fitted values and residuals for
the fit of degree k.

```

The program is written in a generalized form which will read any number of data sets.

The data set supplied specifies 5 data points in the interval [0.0,4.0] with unit weights, to which are to be fitted polynomials, p , of degrees up to 4, subject to the 3 constraints:

```

p(0.0)=1.0,  p'(0.0)=-2.0,  p(4.0)=9.0.

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

```

```

E02 -- Curve and Surface Fitting                                E02AHF
E02AHF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AHF determines the coefficients in the Chebyshev-series representation of the derivative of a polynomial given in Chebyshev-series form.

2. Specification

```

SUBROUTINE E02AHF (NP1, XMIN, XMAX, A, IA1, LA, PATM1,
1                ADIF, IADIF1, LADIF, IFAIL)
INTEGER          NP1, IA1, LA, IADIF1, LADIF, IFAIL

```

DOUBLE PRECISION XMIN, XMAX, A(LA), PATM1, ADIF(LADIF)

3. Description

This routine forms the polynomial which is the derivative of a given polynomial. Both the original polynomial and its derivative are represented in Chebyshev-series form. Given the coefficients a_i , for $i=0,1,\dots,n$, of a polynomial $p(x)$ of degree n , where

$$p(x) = \frac{1}{2} a_0 + a_1 T_1(x) + \dots + a_n T_n(x)$$

the routine returns the coefficients a_i , for $i=0,1,\dots,n-1$, of the polynomial $q(x)$ of degree $n-1$, where

$$q(x) = \frac{dp(x)}{dx} = -a_1 + a_2 T_1(x) + \dots + a_{n-1} T_{n-1}(x).$$

Here $T_j(x)$ denotes the Chebyshev polynomial of the first kind of degree j with argument x . It is assumed that the normalised

variable x in the interval $[-1,+1]$ was obtained from the user's

original variable x in the interval $[x_{\min}, x_{\max}]$ by the linear transformation

$$x = \frac{2x_{\max} - (x_{\min} + x_{\max})}{x_{\max} - x_{\min}}$$

and that the user requires the derivative to be with respect to

the variable x . If the derivative with respect to x is required, set $x_{\max} = 1$ and $x_{\min} = -1$.

Values of the derivative can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of [1] modified to obtain the

derivative with respect to x . Initially setting $a_{n+1} = 0$, the routine forms successively

$$a_{i-1} = a_{i+1} x_{\max}^2 + \frac{-2ia_i}{x_{\min} - x_{\max}}, \quad i=n, n-1, \dots, 1.$$

4. References

- [1] Unknown (1961) Chebyshev-series. Modern Computing Methods, Chapter 8. NPL Notes on Applied Science (2nd Edition). 16 HMSO.

5. Parameters

1: NP1 -- INTEGER Input
On entry: $n+1$, where n is the degree of the given polynomial $p(x)$. Thus NP1 is the number of coefficients in this polynomial. Constraint: $NP1 \geq 1$.

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input
On entry: the lower and upper end-points respectively of the interval $[x_{\min}, x_{\max}]$. The Chebyshev-series

representation is in terms of the normalised variable x , where

$$x = \frac{2x_{\max} - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}.$$

Constraint: $XMAX > XMIN$.

4: A(LA) -- DOUBLE PRECISION array Input
On entry: the Chebyshev coefficients of the polynomial $p(x)$. Specifically, element $1 + i \cdot IA1$ of A must contain the coefficient a_i , for $i=0, 1, \dots, n$. Only these $n+1$ elements

i
will be accessed.

Unchanged on exit, but see ADIF, below.

5: IA1 -- INTEGER Input
On entry: the index increment of A. Most frequently the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if, for example, they are stored in A(1),A(4),A(7),..., then the value of IA1 must be 3. See also Section 8. Constraint: IA1 >= 1.

6: LA -- INTEGER Input
On entry:
the dimension of the array A as declared in the (sub)program from which E02AHF is called.
Constraint: LA >= 1 + (NP1-1)*IA1.

7: PATM1 -- DOUBLE PRECISION Output
On exit: the value of $p(x_{\min})$. If this value is passed to the integration routine E02AJF with the coefficients of $q(x)$, then the original polynomial $p(x)$ is recovered, including its constant coefficient.

8: ADIF(LADIF) -- DOUBLE PRECISION array Output
On exit: the Chebyshev coefficients of the derived polynomial $q(x)$. (The differentiation is with respect to the variable x). Specifically, element $1+i*IADIF1$ of ADIF

contains the coefficient a_i , $i=0,1,\dots,n-1$. Additionally element $1+n*IADIF1$ is set to zero. A call of the routine may have the array name ADIF the same as A, provided that note is taken of the order in which elements are overwritten, when choosing the starting elements and increments IA1 and IADIF1: the coefficients $a_0, a_1, \dots, a_{i-1}$ must be intact

after coefficient a_i is stored. In particular, it is possible to overwrite the a_i completely by having IA1 = IADIF1, and the actual arrays for A and ADIF identical.

9: IADIF1 -- INTEGER Input
On entry: the index increment of ADIF. Most frequently the Chebyshev coefficients are required in adjacent elements of

ADIF, and IADIF1 must be set to 1. However, if, for example, they are to be stored in ADIF(1),ADIF(4),ADIF(7),..., then the value of IADIF1 must be 3. See Section 8. Constraint: IADIF1 $\geq$ 1.

- 10: LADIF -- INTEGER Input
 On entry:
 the dimension of the array ADIF as declared in the
 (sub)program from which E02AHF is called.
 Constraint: LADIF $\geq$ 1+(NP1-1)*IADIF1.
- 11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 On entry NP1 < 1,
 or XMAX $\leq$ XMIN,
 or IA1 < 1,
 or LA $\leq$ (NP1-1)*IA1,
 or IADIF1 < 1,
 or LADIF $\leq$ (NP1-1)*IADIF1.

7. Accuracy

There is always a loss of precision in numerical differentiation, in this case associated with the multiplication by 2i in the formula quoted in Section 3.

8. Further Comments

The time taken by the routine is approximately proportional to n+1.

The increments IA1, IADIF1 are included as parameters to give a degree of flexibility which, for example, allows a polynomial in two variables to be differentiated with respect to either

variable without rearranging the coefficients.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval $[-0.5, 2.5]$. The example program evaluates the 1st and 2nd derivatives of this polynomial at 4 equally spaced points over the interval. (For the purposes of this example, XMIN, XMAX and the Chebyshev coefficients are simply supplied in DATA statements. Normally a program would first read in or generate data and compute the fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02AJF
 E02AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AJF determines the coefficients in the Chebyshev-series representation of the indefinite integral of a polynomial given in Chebyshev-series form.

2. Specification

```

SUBROUTINE E02AJF (NP1, XMIN, XMAX, A, IA1, LA, QATM1,
1               AINT, IAIN1, LAINT, IFAIL)
INTEGER          NP1, IA1, LA, IAIN1, LAINT, IFAIL
DOUBLE PRECISION XMIN, XMAX, A(LA), QATM1, AINT(LAINT)
    
```

3. Description

This routine forms the polynomial which is the indefinite integral of a given polynomial. Both the original polynomial and its integral are represented in Chebyshev-series form. If supplied with the coefficients a_i , for $i=0,1,\dots,n$, of a polynomial $p(x)$ of degree n , where

$$p(x) = -a_0 + a_1 T_1(x) + \dots + a_n T_n(x),$$

the routine returns the coefficients a'_i , for $i=0,1,\dots,n+1$, of the polynomial $q(x)$ of degree $n+1$, where

$$q(x) = -a'_0 + a'_1 T_1(x) + \dots + a'_{n+1} T_{n+1}(x),$$

and

$$q(x) = \int_{\min}^{\max} p(x) dx.$$

Here $T_j(x)$ denotes the Chebyshev polynomial of the first kind of degree j with argument x . It is assumed that the normalised

variable x in the interval $[-1,+1]$ was obtained from the user's original variable x in the interval $[x_{\min}, x_{\max}]$ by the linear transformation

$$x = \frac{2x_{\max} - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}$$

and that the user requires the integral to be with respect to the

variable x . If the integral with respect to x is required, set $x_{\max} = 1$ and $x_{\min} = -1$.

Values of the integral can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of Chebyshev-series [1] modified for integrating with respect to x . Initially taking $a_{n+1} = a_{n+2} = 0$, the routine forms successively

$$a' = \frac{a_{i-1} - a_{i+1}}{2i} * \frac{x_{\max} - x_{\min}}{2}, \quad i=n+1, n, \dots, 1.$$

The constant coefficient a'_0 is chosen so that $q(x)$ is equal to a specified value, QATM1, at the lower end-point of the interval on

which it is defined, $x=-1$, which corresponds to $x=x_{\min}$.

4. References

- [1] Unknown (1961) Chebyshev-series. Modern Computing Methods, Chapter 8. NPL Notes on Applied Science (2nd Edition). 16 HMSO.

5. Parameters

- 1: NP1 -- INTEGER Input
 On entry: n+1, where n is the degree of the given polynomial p(x). Thus NP1 is the number of coefficients in this polynomial. Constraint: NP1 >= 1.
- 2: XMIN -- DOUBLE PRECISION Input
- 3: XMAX -- DOUBLE PRECISION Input
 On entry: the lower and upper end-points respectively of the interval $[x_{\min}, x_{\max}]$. The Chebyshev-series

representation is in terms of the normalised variable x, where

$$x = \frac{2x_{\max} - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}.$$

Constraint: XMAX > XMIN.

- 4: A(LA) -- DOUBLE PRECISION array Input
 On entry: the Chebyshev coefficients of the polynomial p(x). Specifically, element 1+i*IA1 of A must contain the coefficient a_i , for $i=0, 1, \dots, n$. Only these n+1 elements will be accessed.

Unchanged on exit, but see AINT, below.

- 5: IA1 -- INTEGER Input
 On entry: the index increment of A. Most frequently the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if for example, they are stored in A(1),A(4),A(7),..., then the value of IA1 must be 3. See also Section 8. Constraint: IA1 >= 1.
- 6: LA -- INTEGER Input
 On entry:
 the dimension of the array A as declared in the (sub)program from which E02AJF is called.
 Constraint: LA >= 1+(NP1-1)*IA1.
- 7: QATM1 -- DOUBLE PRECISION Input
 On entry: the value that the integrated polynomial is required to have at the lower end-point of its interval of definition, at $x=-1$ which corresponds to $x=x_{\min}$. Thus, QATM1 is a constant of integration and will normally be set to zero by the user.
- 8: AINT(LAINT) -- DOUBLE PRECISION array Output
 On exit: the Chebyshev coefficients of the integral $q(x)$. (The integration is with respect to the variable x , and the constant coefficient is chosen so that $q(x_{\min})$ equals QATM1)
 Specifically, element $1+i*IAINT1$ of AINT contains the coefficient a'_i , for $i=0,1,\dots,n+1$. A call of the routine may have the array name AINT the same as A, provided that note is taken of the order in which elements are overwritten when choosing starting elements and increments IA1 and LAINT1: the coefficients, $a_0, a_1, \dots, a_{i-2}$ must be intact after coefficient a'_i is stored. In particular it is possible to overwrite the a_i entirely by having IA1 = LAINT1, and the actual array for A and AINT identical.
- 9: IAIN1 -- INTEGER Input
 On entry: the index increment of AINT. Most frequently the Chebyshev coefficients are required in adjacent elements of AINT, and IAIN1 must be set to 1. However, if, for example, they are to be stored in AINT(1),AINT(4),AINT(7),..., then the value of IAIN1 must be 3. See also Section 8.

Constraint: IAIN1 $\geq$ 1.

- 10: LAINT -- INTEGER Input
 On entry:
 the dimension of the array AINT as declared in the
 (sub)program from which E02AJF is called.
 Constraint: LAINT $\geq$ 1+NP1*IAINT1.
- 11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 On entry NP1 < 1,
 or XMAX $\leq$ XMIN,
 or IA1 < 1,
 or LA $\leq$ (NP1-1)*IA1,
 or IAIN1 < 1,
 or LAINT $\leq$ NP1*IAINT1.

7. Accuracy

In general there is a gain in precision in numerical integration, in this case associated with the division by 2i in the formula quoted in Section 3.

8. Further Comments

The time taken by the routine is approximately proportional to n+1.

The increments IA1, IAIN1 are included as parameters to give a degree of flexibility which, for example, allows a polynomial in two variables to be integrated with respect to either variable without rearranging the coefficients.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval $[-0.5, 2.5]$. The example program evaluates the integral of the polynomial from 0.0 to 2.0. (For the purpose of this example, XMIN, XMAX and the Chebyshev coefficients are simply supplied in DATA statements. Normally a program would read in or generate data and compute the fitted polynomial).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02AKF
E02AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02AKF evaluates a polynomial from its Chebyshev-series representation, allowing an arbitrary index increment for accessing the array of coefficients.

2. Specification

```
SUBROUTINE E02AKF (NP1, XMIN, XMAX, A, IA1, LA, X, RESULT,
1                IFAIL)
      INTEGER      NP1, IA1, LA, IFAIL
      DOUBLE PRECISION XMIN, XMAX, A(LA), X, RESULT
```

3. Description

If supplied with the coefficients a_i , for $i=0, 1, \dots, n$, of a

polynomial $p(x)$ of degree n , where

$$p(x) = -a_0 + a_1 T_1(x) + \dots + a_n T_n(x),$$

this routine returns the value of $p(x)$ at a user-specified value

of the variable x . Here $T_j(x)$ denotes the Chebyshev polynomial of
 j

the first kind of degree j with argument x . It is assumed that

the independent variable x in the interval $[-1,+1]$ was obtained
 from the user's original variable x in the interval $[x_{\min}, x_{\max}]$
 $\min \quad \max$

by the linear transformation

$$x = \frac{2x_{\max} - (x_{\min} + x_{\max})}{x_{\max} - x_{\min}}.$$

The coefficients a_i may be supplied in the array A , with any
 i

increment between the indices of array elements which contain
 successive coefficients. This enables the routine to be used in
 surface fitting and other applications, in which the array might
 have two or more dimensions.

The method employed is based upon the three-term recurrence
 relation due to Clenshaw [1], with modifications due to Reinsch
 and Gentleman (see [4]). For further details of the algorithm and
 its use see Cox [2] and Cox and Hayes [3].

5. Parameters

- 1: NP1 -- INTEGER Input
 On entry: n+1, where n is the degree of the given

 polynomial p(x). Constraint: NP1 >= 1.
- 2: XMIN -- DOUBLE PRECISION Input
- 3: XMAX -- DOUBLE PRECISION Input
 On entry: the lower and upper end-points respectively of
 the interval [x_{min}, x_{max}]. The Chebyshev-series

 representation is in terms of the normalised variable x,
 where
- $$x = \frac{2x - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}.$$
- Constraint: XMIN < XMAX.
- 4: A(LA) -- DOUBLE PRECISION array Input
 On entry: the Chebyshev coefficients of the polynomial p(x).
 Specifically, element 1+i*IA1 must contain the coefficient
 a_i, for i=0,1,...,n. Only these n+1 elements will be
 accessed.
- 5: IA1 -- INTEGER Input
 On entry: the index increment of A. Most frequently, the
 Chebyshev coefficients are stored in adjacent elements of A,
 and IA1 must be set to 1. However, if, for example, they are
 stored in A(1),A(4),A(7),..., then the value of IA1 must be
 3. Constraint: IA1 >= 1.
- 6: LA -- INTEGER Input
 On entry:
 the dimension of the array A as declared in the (sub)program
 from which E02AKF is called.
 Constraint: LA >= (NP1-1)*IA1+1.
- 7: X -- DOUBLE PRECISION Input
 On entry: the argument x at which the polynomial is to be
 evaluated. Constraint: XMIN <= X <= XMAX.
- 8: RESULT -- DOUBLE PRECISION Output

On exit: the value of the polynomial $p(x)$.

9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry $NP1 < 1$,

or $IA1 < 1$,

or $LA \leq (NP1-1)*IA1$,

or $XMIN \geq XMAX$.

IFAIL= 2

X does not satisfy the restriction $XMIN \leq X \leq XMAX$.

7. Accuracy

The rounding errors are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients $a_i + (\delta_i) a_i$. The ratio of the sum of the absolute values of the $(\delta_i) a_i$ to the sum of the absolute values of the a_i is less than a small multiple of $(n+1)*\text{machine precision}$.

8. Further Comments

The time taken by the routine is approximately proportional to $n+1$.

9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval $[-0.5, 2.5]$. The example program evaluates the polynomial at 4 equally spaced points over the interval. (For the purposes of this example, $XMIN$, $XMAX$ and the Chebyshev coefficients are supplied in DATA statements. Normally a program would first read in or generate data and compute the

fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02BAF
 E02BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BAF computes a weighted least-squares approximation to an arbitrary set of data points by a cubic spline with knots prescribed by the user. Cubic spline interpolation can also be carried out.

2. Specification

```

      SUBROUTINE E02BAF (M, NCAP7, X, Y, W, LAMDA, WORK1, WORK2,
1      C, SS, IFAIL)
      INTEGER          M, NCAP7, IFAIL
      DOUBLE PRECISION X(M), Y(M), W(M), LAMDA(NCAP7), WORK1(M),
1      WORK2(4*NCAP7), C(NCAP7), SS
```

3. Description

This routine determines a least-squares cubic spline approximation $s(x)$ to the set of data points (x_r, y_r) with weights

w_r , for $r=1,2,\dots,m$. The value of $NCAP7 = n+7$, where n is the number of intervals of the spline (one greater than the number of interior knots), and the values of the knots $(\lambda_5), (\lambda_6), \dots, (\lambda_{n+3})$, interior to the data interval, are prescribed by the user.

$s(x)$ has the property that it minimizes (θ) , the sum of squares of the weighted residuals (ϵ_r) , for $r=1,2,\dots,m$,

where

$$(\epsilon) = w (y - s(x)).$$

r r r r

The routine produces this minimizing value of (θ) and the

coefficients $c_1, c_2, \dots, c_q$, where $q=n+3$, in the B-spline representation

$$s(x) = \sum_{i=1}^q c_i N_i(x).$$

Here $N_i(x)$ denotes the normalised B-spline of degree 3 defined upon the knots $(\lambda)_i, (\lambda)_{i+1}, \dots, (\lambda)_{i+4}$.

In order to define the full set of B-splines required, eight additional knots $(\lambda)_1, (\lambda)_2, (\lambda)_3, (\lambda)_4$ and $(\lambda)_{n+4}, (\lambda)_{n+5}, (\lambda)_{n+6}, (\lambda)_{n+7}$ are inserted automatically by the routine. The first four of these are set equal to the smallest x_r and the last four to the largest x_r .

The representation of $s(x)$ in terms of B-splines is the most compact form possible in that only $n+3$ coefficients, in addition to the $n+7$ knots, fully define $s(x)$.

The method employed involves forming and then computing the least-squares solution of a set of m linear equations in the

coefficients c_i ($i=1, 2, \dots, n+3$). The equations are formed using a recurrence relation for B-splines that is unconditionally stable (Cox [1], de Boor [5]), even for multiple (coincident) knots. The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotations (Gentleman [6] and [7]). This requires only one equation to be stored at a time. Full advantage is taken of the

structure of the equations, there being at most four non-zero values of $N(x)$ for any value of x and hence at most four

i
coefficients in each equation.

For further details of the algorithm and its use see Cox [2], [3] and [4].

Subsequent evaluation of $s(x)$ from its B-spline representation may be carried out using E02BBF. If derivatives of $s(x)$ are also required, E02BCF may be used. E02BDF can be used to compute the definite integral of $s(x)$.

5. Parameters

1: M -- INTEGER Input
On entry: the number m of data points. Constraint: $M \geq MDIST \geq 4$, where $MDIST$ is the number of distinct x values in the data.

- 2: NCAP7 -- INTEGER Input
- On entry: $n+7$, where n is the number of intervals of the spline (which is one greater than the number of interior knots, the knots strictly within the range x_1 to x_m) over which the spline is defined. Constraint: $8 \leq \text{NCAP7} \leq \text{MDIST} + 4$, where MDIST is the number of distinct x values in the data.
- 3: X(M) -- DOUBLE PRECISION array Input
 On entry: the values x_r of the independent variable (abscissa), for $r=1,2,\dots,m$. Constraint: $x_1 \leq x_2 \leq \dots \leq x_m$.
- 4: Y(M) -- DOUBLE PRECISION array Input
 On entry: the values y_r of the dependent variable (ordinate), for $r=1,2,\dots,m$.
- 5: W(M) -- DOUBLE PRECISION array Input
 On entry: the values w_r of the weights, for $r=1,2,\dots,m$.
 For advice on the choice of weights, see the Chapter Introduction. Constraint: $W(r) > 0$, for $r=1,2,\dots,m$.
- 6: LAMDA(NCAP7) -- DOUBLE PRECISION array Input/Output
 On entry: LAMDA(i) must be set to the (i-4)th (interior) knot, (λ_i) , for $i=5,6,\dots,n+3$. Constraint: $X(1) < \lambda_5 \leq \lambda_6 \leq \dots \leq \lambda_{\text{NCAP7}-4} < X(M)$. On exit: the input values are unchanged, and LAMDA(i), for $i = 1, 2, 3, 4, \text{NCAP7}-3, \text{NCAP7}-2, \text{NCAP7}-1$, NCAP7 contains the additional (exterior) knots introduced by the routine. For advice on the choice of knots, see Section 3.3 of the Chapter Introduction.
- 7: WORK1(M) -- DOUBLE PRECISION array Workspace
- 8: WORK2(4*NCAP7) -- DOUBLE PRECISION array Workspace
- 9: C(NCAP7) -- DOUBLE PRECISION array Output
 On exit: the coefficient c_i of the B-spline $N_i(x)$, for

$i=1,2,\dots,n+3$. The remaining elements of the array are not used.

10: SS -- DOUBLE PRECISION Output
 On exit: the residual sum of squares, (theta).

11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The knots fail to satisfy the condition

$X(1) < \text{LAMDA}(5) \leq \text{LAMDA}(6) \leq \dots \leq \text{LAMDA}(\text{NCAP7}-4) < X(M)$.
 Thus the knots are not in correct order or are not interior to the data interval.

IFAIL= 2

The weights are not all strictly positive.

IFAIL= 3

The values of $X(r)$, for $r = 1, 2, \dots, M$ are not in non-decreasing order.

IFAIL= 4

$\text{NCAP7} < 8$ (so the number of interior knots is negative) or $\text{NCAP7} > \text{MDIST} + 4$, where MDIST is the number of distinct x values in the data (so there cannot be a unique solution).

IFAIL= 5

The conditions specified by Schoenberg and Whitney [8] fail to hold for at least one subset of the distinct data abscissae. That is, there is no subset of $\text{NCAP7}-4$ strictly increasing values, $X(R(1)), X(R(2)), \dots, X(R(\text{NCAP7}-4))$, among the abscissae such that

$X(R(1)) < \text{LAMDA}(1) < X(R(5)),$

$X(R(2)) < \text{LAMDA}(2) < X(R(6)),$

...

$X(R(\text{NCAP7}-8)) < \text{LAMDA}(\text{NCAP7}-8) < X(R(\text{NCAP7}-4)).$

This means that there is no unique solution: there are regions containing too many knots compared with the number of data points.

7. Accuracy

The rounding errors committed are such that the computed coefficients are exact for a slightly perturbed set of ordinates $y + (\delta y)_r$. The ratio of the root-mean-square value for the $(\delta y)_r$ to the root-mean-square value of the y_r can be expected to be less than a small multiple of $(\kappa) * m * \text{machine precision}$, where (κ) is a condition number for the problem. Values of (κ) for 20-30 practical data sets all proved to lie between 4.5 and 7.8 (see Cox [3]). (Note that for these data sets, replacing the coincident end knots at the end-points x_1 and x_m used in the routine by various choices of non-coincident exterior knots gave values of (κ) between 16 and 180. Again see Cox [3] for further details.) In general we would not expect (κ) to be large unless the choice of knots results in near-violation of the Schoenberg-Whitney conditions.

A cubic spline which adequately fits the data and is free from spurious oscillations is more likely to be obtained if the knots are chosen to be grouped more closely in regions where the function (underlying the data) or its derivatives change more rapidly than elsewhere.

8. Further Comments

The time taken by the routine is approximately $C * (2m + n + 7)$ seconds, where C is a machine-dependent constant.

Multiple knots are permitted as long as their multiplicity does not exceed 4, the complete set of knots must satisfy

$(\lambda)_i < (\lambda)_{i+4}$, for $i=1,2,\dots,n+3$, (cf. Section 6). At a knot of multiplicity one (the usual case), $s(x)$ and its first two derivatives are continuous. At a knot of multiplicity two, $s(x)$ and its first derivative are continuous. At a knot of multiplicity three, $s(x)$ is continuous, and at a knot of multiplicity four, $s(x)$ is generally discontinuous.

The routine can be used efficiently for cubic spline

interpolation, if $m=n+3$. The abscissae must then of course satisfy $x_1 < x_2 < \dots < x_m$. Recommended values for the knots in this

case are $(\lambda_i)_{i=5,6,\dots,n+3}$, for $i=5,6,\dots,n+3$.

9. Example

Determine a weighted least-squares cubic spline approximation with five intervals (four interior knots) to a set of 14 given data points. Tabulate the data and the corresponding values of the approximating spline, together with the residual errors, and also the values of the approximating spline at points half-way between each pair of adjacent data points.

The example program is written in a general form that will enable

a cubic spline approximation with n intervals ($n-1$ interior knots) to be obtained to m data points, with arbitrary positive weights, and the approximation to be tabulated. Note that E02BBF is used to evaluate the approximating spline. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02BBF
E02BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BBF evaluates a cubic spline from its B-spline representation.

2. Specification

SUBROUTINE E02BBF (NCAP7, LAMDA, C, X, S, IFAIL)
INTEGER NCAP7, IFAIL

DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S

3. Description

This routine evaluates the cubic spline $s(x)$ at a prescribed argument x from its augmented knot set (λ_i) , for

$i=1,2,\dots,n+7$, (see E02BAF) and from the coefficients c_i , for $i=1,2,\dots,q$ in its B-spline representation

$$s(x) = \sum_{i=1}^q c_i N_i(x)$$

Here $q=n+3$, where n is the number of intervals of the spline, and $N_i(x)$ denotes the normalised B-spline of degree 3 defined upon the knots $(\lambda_i), (\lambda_{i+1}), \dots, (\lambda_{i+4})$. The prescribed argument x must satisfy $(\lambda_4) \leq x \leq (\lambda_{n+4})$.

It is assumed that $(\lambda_j) \geq (\lambda_{j-1})$, for $j=2,3,\dots,n+7$, and $(\lambda_4) > (\lambda_{n+4})$.

The method employed is that of evaluation by taking convex combinations due to de Boor [4]. For further details of the algorithm and its use see Cox [1] and [3].

It is expected that a common use of E02BBF will be the evaluation of the cubic spline approximations produced by E02BAF. A generalization of E02BBF which also forms the derivative of $s(x)$ is E02BCF. E02BCF takes about 50% longer than E02BBF.

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: $n+7$, where n is the number of intervals (one greater than the number of interior knots, the knots strictly within the range (λ_4) to (λ_{n+4}) over

which the spline is defined. Constraint: $\text{NCAP7} \geq 8$.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input
 On entry: LAMDA(j) must be set to the value of the j th member of the complete set of knots, (λ_j) for

$j=1,2,\dots,n+7$. Constraint: the LAMDA(j) must be in non-decreasing order with $\text{LAMDA}(\text{NCAP7}-3) > \text{LAMDA}(4)$.

3: C(NCAP7) -- DOUBLE PRECISION array Input
 On entry: the coefficient c_i of the B-spline $N_i(x)$, for

$i=1,2,\dots,n+3$. The remaining elements of the array are not used.

4: X -- DOUBLE PRECISION Input
 On entry: the argument x at which the cubic spline is to be evaluated. Constraint: $\text{LAMDA}(4) \leq X \leq \text{LAMDA}(\text{NCAP7}-3)$.

5: S -- DOUBLE PRECISION Output
 On exit: the value of the spline, $s(x)$.

6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential

Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The argument X does not satisfy $\text{LAMDA}(4) \leq X \leq \text{LAMDA}(\text{NCAP7}-3)$.

In this case the value of S is set arbitrarily to zero.

IFAIL= 2

$\text{NCAP7} < 8$, the number of interior knots is negative.

7. Accuracy

The computed value of $s(x)$ has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by $18 * c_{\max} * \text{machine precision}$, where $c_{\max}$ is

the largest in modulus of c_j, c_{j+1}, c_{j+2} and c_{j+3} , and j is an integer such that $(\text{lambda})_{j+3} \leq x \leq (\text{lambda})_{j+4}$. If c_j, c_{j+1}, c_{j+2} and c_{j+3} are all of the same sign, then the computed value of $s(x)$ has a relative error not exceeding $20 * \text{machine precision}$ in modulus. For further details see Cox [2].

8. Further Comments

The time taken by the routine is approximately $C * (1 + 0.1 * \log(n+7))$ seconds, where C is a machine-dependent constant.

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this would result in a computation time approximately linear in $n+7$ instead of $\log(n+7)$. All the conditions are tested in E02BAF, however.

9. Example

Evaluate at 9 equally-spaced points in the interval $1.0 \leq x \leq 9.0$ the cubic spline with (augmented) knots 1.0, 1.0, 1.0, 1.0, 3.0,

6.0, 8.0, 9.0, 9.0, 9.0, 9.0 and normalised cubic B-spline coefficients 1.0, 2.0, 4.0, 7.0, 6.0, 4.0, 3.0.

The example program is written in a general form that will enable

a cubic spline with n intervals, in its normalised cubic B-spline form, to be evaluated at m equally-spaced points in the interval

$LAMDA(4) \leq x \leq LAMDA(n+4)$. The program is self-starting in that any number of data sets may be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02BCF
E02BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BCF evaluates a cubic spline and its first three derivatives from its B-spline representation.

2. Specification

```
SUBROUTINE E02BCF (NCAP7, LAMDA, C, X, LEFT, S, IFAIL)
  INTEGER          NCAP7, LEFT, IFAIL
  DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S(4)
```

3. Description

This routine evaluates the cubic spline $s(x)$ and its first three derivatives at a prescribed argument x . It is assumed that $s(x)$ is represented in terms of its B-spline coefficients c_i , for

$i=1,2,\dots,n+3$ and (augmented) ordered knot set (λ_i) , for

$i=1,2,\dots,n+7$, (see E02BAF),

$$s(x) = \sum_{i=1}^q c_i N_i(x)$$

Here $q=n+3$, n is the number of intervals of the spline and $N_i(x)$

denotes the normalised B-spline of degree 3 (order 4) defined upon the knots $(\lambda_{i-1}), (\lambda_i), \dots, (\lambda_{i+4})$. The prescribed argument x must satisfy

$$(\lambda_4) \leq x \leq (\lambda_{n+4})$$

At a simple knot (λ_i) (one satisfying

$(\lambda_{i-1}) < (\lambda_i) < (\lambda_{i+1})$), the third derivative of the spline is in general discontinuous. At a multiple knot (two or more knots with the same value), lower derivatives, and even the spline itself, may be discontinuous. Specifically, at a point $x=u$ where (exactly) r knots coincide (such a point is termed a knot of multiplicity r), the values of the derivatives of order $4-j$, for $j=1,2,\dots,r$, are in general discontinuous. (Here $1 \leq r \leq 4$; $r > 4$ is not meaningful.) The user must specify whether the value at such a point is required to be the left- or right-hand derivative.

The method employed is based upon:

- (i) carrying out a binary search for the knot interval containing the argument x (see Cox [3]),
- (ii) evaluating the non-zero B-splines of orders 1,2,3 and 4 by recurrence (see Cox [2] and [3]),
- (iii) computing all derivatives of the B-splines of order 4 by applying a second recurrence to these computed B-spline values (see de Boor [1]),
- (iv) multiplying the 4th-order B-spline values and their derivative by the appropriate B-spline coefficients, and summing, to yield the values of $s(x)$ and its derivatives.

E02BCF can be used to compute the values and derivatives of cubic spline fits and interpolants produced by E02BAF.

If only values and not derivatives are required, E02BBF may be used instead of E02BCF, which takes about 50% longer than E02BBF.

- [3] Cox M G (1978) The Numerical Evaluation of a Spline from its B-spline Representation. J. Inst. Math. Appl. 21 135--143.

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: $n+7$, where n is the number of intervals of the spline (which is one greater than the number of interior knots, the knots strictly within the range (lambda) 4
to (lambda) over which the spline is defined).
 $n+4$
Constraint: NCAP7 ≥ 8 .

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input
On entry: LAMDA(j) must be set to the value of the j th member of the complete set of knots, (lambda) , for j

$j=1,2,\dots,n+7$. Constraint: the LAMDA(j) must be in non-decreasing order with

LAMDA(NCAP7-3) > LAMDA(4).

3: C(NCAP7) -- DOUBLE PRECISION array Input
On entry: the coefficient c_i of the B-spline $N_i(x)$, for i

$i=1,2,\dots,n+3$. The remaining elements of the array are not used.

4: X -- DOUBLE PRECISION Input
On entry: the argument x at which the cubic spline and its

derivatives are to be evaluated. Constraint: LAMDA(4) <= X
<= LAMDA(NCAP7-3).

5: LEFT -- INTEGER Input
On entry: specifies whether left- or right-hand values of the spline and its derivatives are to be computed (see Section 3). Left- or right-hand values are formed according to whether LEFT is equal or not equal to 1. If x does not coincide with a knot, the value of LEFT is immaterial. If x = LAMDA(4), right-hand values are computed, and if x = LAMDA(NCAP7-3), left-hand values are formed, regardless of the value of LEFT.

6: S(4) -- DOUBLE PRECISION array Output
On exit: S(j) contains the value of the (j-1)th derivative of the spline at the argument x, for j = 1,2,3,4. Note that S(1) contains the value of the spline.

7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
NCAP7 < 8, the number of intervals is not positive.

IFAIL= 2
Either LAMDA(4) >= LAMDA(NCAP7-3), the range over which s(x) is defined is null or negative in length, or X is an invalid argument, X < LAMDA(4) or X > LAMDA(NCAP7-3).

7. Accuracy

The computed value of s(x) has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by $18 * c_{\max} * \text{machine precision}$, where $c_{\max}$ is the largest in modulus of c_j, c_{j+1}, c_{j+2} and c_{j+3} , and j is an integer such that $(\text{lambda})_{j+3} \leq x \leq (\text{lambda})_{j+4}$. If c_j, c_{j+1}, c_{j+2} and c_{j+3} are all of the same sign, then the computed value of

$j+3$
 $s(x)$ has relative error bounded by $18 \times \text{machine precision}$. For full details see Cox [3].

No complete error analysis is available for the computation of the derivatives of $s(x)$. However, for most practical purposes the absolute errors in the computed derivatives should be small.

8. Further Comments

The time taken by this routine is approximately linear in

$\log(n+7)$.

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this

would result in a computation time approximately linear in $n+7$

instead of $\log(n+7)$. All the conditions are tested in EO2BAF, however.

9. Example

Compute, at the 7 arguments $x = 0, 1, 2, 3, 4, 5, 6$, the left- and right-hand values and first 3 derivatives of the cubic spline defined over the interval $0 \leq x \leq 6$ having the 6 interior knots $x = 1, 3, 3, 3, 4, 4$, the 8 additional knots $0, 0, 0, 0, 6, 6, 6, 6$, and the 10 B-spline coefficients 10, 12, 13, 15, 22, 26, 24, 18, 14, 12.

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

n	m
LAMDA(j),	for $j = 1, 2, \dots, \text{NCAP7}$
C(j),	for $j = 1, 2, \dots, \text{NCAP7}-4$
$x(i)$,	for $i = 1, 2, \dots, m$

The example program is written in a general form that will enable the values and derivatives of a cubic spline having an arbitrary number of knots to be evaluated at a set of arbitrary points. Any

number of data sets may be supplied. The only changes required to the program relate to the dimensions of the arrays LAMDA and C.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02BDF
 E02BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BDF computes the definite integral of a cubic spline from its B-spline representation.

2. Specification

```
SUBROUTINE E02BDF (NCAP7, LAMDA, C, DEFINT, IFAIL)
  INTEGER          NCAP7, IFAIL
  DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), DEFINT
```

3. Description

This routine computes the definite integral of the cubic spline $s(x)$ between the limits $x=a$ and $x=b$, where a and b are respectively the lower and upper limits of the range over which $s(x)$ is defined. It is assumed that $s(x)$ is represented in terms

of its B-spline coefficients c_i , for $i=1,2,\dots,n+3$ and

(augmented) ordered knot set (λ_i) , for $i=1,2,\dots,n+7$, with
 $(\lambda_i) = a$, for $i = 1,2,3,4$ and $(\lambda_i) = b$, for

$i=n+4,n+5,n+6,n+7$, (see E02BAF),

q
 --

$$s(x) = \sum_{i=1}^q c_i N_i(x).$$

Here $q=n+3$, n is the number of intervals of the spline and $N_i(x)$ denotes the normalised B-spline of degree 3 (order 4) defined upon the knots $(\lambda_i), (\lambda_{i+1}), \dots, (\lambda_{i+4})$.

The method employed uses the formula given in Section 3 of Cox [1].

E02BDF can be used to determine the definite integrals of cubic spline fits and interpolants produced by E02BAF.

4. References

- [1] Cox M G (1975) An Algorithm for Spline Interpolation. J. Inst. Math. Appl. 15 95--108.

5. Parameters

1: NCAP7 -- INTEGER Input

On entry: $n+7$, where n is the number of intervals of the spline (which is one greater than the number of interior knots, the knots strictly within the range a to b) over which the spline is defined. Constraint: $NCAP7 \geq 8$.

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input
On entry: LAMDA(j) must be set to the value of the j th member of the complete set of knots, (λ_j) for j

$j=1, 2, \dots, n+7$. Constraint: the LAMDA(j) must be in non-decreasing order with $LAMDA(NCAP7-3) > LAMDA(4)$ and satisfy $LAMDA(1)=LAMDA(2)=LAMDA(3)=LAMDA(4)$ and

$LAMDA(NCAP7-3)=LAMDA(NCAP7-2)=LAMDA(NCAP7-1)=LAMDA(NCAP7)$.

3: C(NCAP7) -- DOUBLE PRECISION array Input
On entry: the coefficient c_i of the B-spline $N_i(x)$, for i

$i=1,2,\dots,n+3$. The remaining elements of the array are not used.

- 4: DEFINT -- DOUBLE PRECISION Output
 On exit: the value of the definite integral of $s(x)$ between
 the limits $x=a$ and $x=b$, where $a=(\text{lambda})$ and $b=(\text{lambda})$.
4 $n+4$
- 5: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1
 NCAP7 < 8, the number of intervals is not positive.

IFAIL= 2
 At least one of the following restrictions on the knots is
 violated:
 $\text{LAMDA}(\text{NCAP7}-3) > \text{LAMDA}(4)$,

 $\text{LAMDA}(j) \geq \text{LAMDA}(j-1)$,
 for $j = 2,3,\dots,\text{NCAP7}$, with equality in the cases
 $j=2,3,4,\text{NCAP7}-2,\text{NCAP7}-1$, and NCAP7 .

7. Accuracy

The rounding errors are such that the computed value of the
 integral is exact for a slightly perturbed set of B-spline
 coefficients c_i differing in a relative sense from those supplied
 by no more than $2.2*(n+3)*\text{machine precision}$.

8. Further Comments

The time taken by the routine is approximately proportional to

$n+7$.

9. Example

Determine the definite integral over the interval $0 \leq x \leq 6$ of a cubic spline having 6 interior knots at the positions $(\text{lambda})=1, 3, 3, 3, 4, 4$, the 8 additional knots $0, 0, 0, 0, 6, 6, 6, 6$, and the 10 B-spline coefficients $10, 12, 13, 15, 22, 26, 24, 18, 14, 12$.

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

```

n

LAMDA(j) for j = 1,2,...,NCAP7
,
C(j),      for j = 1,2,...,NCAP7-3

```

The example program is written in a general form that will enable the definite integral of a cubic spline having an arbitrary number of knots to be computed. Any number of data sets may be supplied. The only changes required to the program relate to the dimensions of the arrays LAMDA and C.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

E02 -- Curve and Surface Fitting                                E02BEF
E02BEF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02BEF computes a cubic spline approximation to an arbitrary set of data points. The knots of the spline are located automatically, but a single parameter must be specified to control the trade-off between closeness of fit and smoothness of fit.

2. Specification

```

SUBROUTINE EO2BEF (START, M, X, Y, W, S, NEST, N, LAMDA,
1                  C, FP, WRK, LWRK, IWRK, IFAIL)
INTEGER           M, NEST, N, LWRK, IWRK(NEST), IFAIL
DOUBLE PRECISION  X(M), Y(M), W(M), S, LAMDA(NEST), C(NEST),
1                  FP, WRK(LWRK)
CHARACTER*1       START

```

3. Description

This routine determines a smooth cubic spline approximation $s(x)$ to the set of data points (x_r, y_r) , with weights w_r , for $r=1,2,\dots,m$.

The spline is given in the B-spline representation

$$s(x) = \sum_{i=1}^{n-4} c_i N_i(x) \quad (1)$$

where $N_i(x)$ denotes the normalised cubic B-spline defined upon the knots $(\lambda_i, \lambda_{i+1}, \dots, \lambda_{i+4})$.

The total number n of these knots and their values $(\lambda_1, \dots, \lambda_n)$ are chosen automatically by the routine.

The knots $(\lambda_5, \dots, \lambda_{n-4})$ are the interior knots; they divide the approximation interval $[x_1, x_m]$ into $n-7$ sub-intervals.

The coefficients $c_1, c_2, \dots, c_{n-4}$ are then determined as the solution of the following constrained minimization problem:

minimize

$$(\eta) = \sum_{i=5}^{n-4} (\delta_i)^2 \quad (2)$$

subject to the constraint

m

$$(\theta) = \frac{\sum_{i=1}^n w_i (y_i - s(x_i))^2}{\sum_{i=1}^n w_i} \leq S \quad (3)$$

where: $(\Delta)_i$ stands for the discontinuity jump in the third order derivative of $s(x)$ at the interior knot $(\lambda)_i$,

$(\epsilon)_r$ denotes the weighted residual $w_r (y_r - s(x_r))$,

and S is a non-negative number to be specified by the user.

The quantity (η) can be seen as a measure of the (lack of) smoothness of $s(x)$, while closeness of fit is measured through (θ) . By means of the parameter S , 'the smoothing factor', the user will then control the balance between these two (usually conflicting) properties. If S is too large, the spline will be too smooth and signal will be lost (underfit); if S is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline $((\theta)=0)$ if S is set to zero, and the weighted least-squares cubic polynomial $((\eta)=0)$ if S is set very large. Experimenting with S values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of S .)

The method employed is outlined in Section 8.3 and fully described in Dierckx [1], [2] and [3]. It involves an adaptive strategy for locating the knots of the cubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline, or of its derivatives or definite integral, can subsequently be computed by calling E02BBF, E02BCF or E02BDF, as described in Section 8.4.

- [4] Reinsch C H (1967) Smoothing by Spline Functions. Num. Math. 10 177--183.

5. Parameters

1: START -- CHARACTER*1 Input
 On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters N, LAMDA, WRK or IWRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters N, LAMDA, WRK, and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: M -- INTEGER Input
 On entry: m, the number of data points. Constraint: M >= 4.

3: X(M) -- DOUBLE PRECISION array Input
 On entry: the values x_r of the independent variable
 (abscissa) x , for $r=1,2,\dots,m$. Constraint: $x_1 < x_2 < \dots < x_m$

4: Y(M) -- DOUBLE PRECISION array Input
 On entry: the values y_r of the dependent variable
 (ordinate) y , for $r=1,2,\dots,m$.

5: W(M) -- DOUBLE PRECISION array Input
 On entry: the values w_r of the weights, for $r=1,2,\dots,m$.
 For advice on the choice of weights, see the Chapter Introduction, Section 2.1.2. Constraint: $W(r) > 0$, for $r=1,2,\dots,m$.

6: S -- DOUBLE PRECISION Input
 On entry: the smoothing factor, S.

If S=0.0, the routine returns an interpolating spline.

If S is smaller than machine precision, it is assumed equal

to zero.

For advice on the choice of S, see Section 3 and Section 8.2
Constraint: $S \geq 0.0$.

- 7: NEST -- INTEGER Input
On entry: an over-estimate for the number, n, of knots required. Constraint: $NEST \geq 8$. In most practical situations, $NEST = M/2$ is sufficient. NEST never needs to be larger than $M + 4$, the number of knots needed for interpolation ($S = 0.0$).

- 8: N -- INTEGER Input/Output
On entry: if the warm start option is used, the value of N must be left unchanged from the previous call. On exit: the total number, n, of knots of the computed spline.

- 9: LAMDA(NEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values LAMDA(1), LAMDA(2), ..., LAMDA(N) must be left unchanged from the previous call. On exit: the knots of the spline, the positions of the interior knots LAMDA(5), LAMDA(6), ..., LAMDA(N-4) as well as the positions of the additional knots

$$LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = x_1$$

$$LAMDA(N-3) = LAMDA(N-2) = LAMDA(N-1) = LAMDA(N) = x_m$$
for the B-spline representation.

- 10: C(NEST) -- DOUBLE PRECISION array Output
On exit: the coefficient c_i of the B-spline $N_i(x)$ in the spline approximation $s(x)$, for $i=1,2,\dots,n-4$.

- 11: FP -- DOUBLE PRECISION Output
On exit: the sum of the squared weighted residuals, (theta), of the computed spline approximation. If $FP = 0.0$, this is an interpolating spline. FP should equal S within a relative tolerance of 0.001 unless $n=8$ when the spline has no interior knots and so is simply a cubic polynomial. For knots to be inserted, S must be set to a value below the value of FP produced in this case.

- 12: WRK(LWRK) -- DOUBLE PRECISION array Workspace
On entry: if the warm start option is used, the values WRK(1), ..., WRK(n) must be left unchanged from the previous call.

- 13: LWRK -- INTEGER Input

On entry:
 the dimension of the array WRK as declared in the
 (sub)program from which E02BEF is called.
 Constraint: $LWRK \geq 4 \cdot M + 16 \cdot NEST + 41$.

- 14: IWRK(NEST) -- INTEGER array Workspace
 On entry: if the warm start option is used, the values IWRK
 (1), ..., IWRK(n) must be left unchanged from the previous
 call.

This array is used as workspace.

- 15: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry START /= 'C' or 'W',

or $M < 4$,

or $S < 0.0$,

or $S = 0.0$ and $NEST < M + 4$,

or $NEST < 8$,

or $LWRK < 4 \cdot M + 16 \cdot NEST + 41$.

IFAIL= 2

The weights are not all strictly positive.

IFAIL= 3

The values of $X(r)$, for $r=1,2,\dots,M$, are not in strictly
 increasing order.

IFAIL= 4

The number of knots required is greater than NEST. Try
 increasing NEST and, if necessary, supplying larger arrays

for the parameters LAMDA, C, WRK and IWRK. However, if NEST is already large, say $NEST > M/2$, then this error exit may indicate that S is too small.

IFAIL= 5

The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) - perhaps by only a small amount, however.

7. Accuracy

On successful exit, the approximation returned is such that its weighted sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if $n=8$, FP may be significantly less than S: in this case the computed spline is simply a weighted least-squares polynomial approximation of degree 3, a spline with no interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02BEF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02BEF is to be called for different values of S, much time can be saved by setting START =

8.2. Choice of S

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of w_r would

be the same for all r , equal to $(\sigma_r)^2$, say. In this case,

choosing the smoothing factor S in the range $(\sigma_r)^2 (m \pm \sqrt{2m})$, as suggested by Reinsch [4], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of S will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for S and so determine the least-squares cubic polynomial; the value returned for FP, call it FP , gives an upper bound for S.

Then progressively decrease the value of S to obtain closer fits
 - say by a factor of 10 in the beginning, $S=FP/10$, $S=FP$

0 0

/100, and so on, and more carefully as the approximation shows more details.

The number of knots of the spline returned, and their location, generally depend on the value of S and on the behaviour of the function underlying the data. However, if E02BEF is called with $START = 'W'$, the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of S and $START = 'W'$, a fit can finally be accepted as satisfactory, it may be worthwhile to call E02BEF once more with the selected value for S but now using $START = 'C'$. Often, E02BEF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.3. Outline of Method Used

If $S=0$, the requisite number of knots is known in advance, $n=m+4$; the interior knots are located immediately as $(\lambda_i) = x_{i-2}$, for $i=5,6,\dots,n-4$. The corresponding least-squares spline (see E02BAF) is then an interpolating spline and therefore a solution of the problem.

If $S>0$, a suitable knot set is built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a spline is fitted to the data by least-squares (see E02BAF) and (θ) , the weighted sum of squares of residuals, is computed. If $(\theta)>S$, new knots are added to the knot set to reduce (θ) at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of S and on the progress made so far in reducing (θ) . Sooner or later, we find that $(\theta)\leq S$ and at that point the knot set is accepted. The routine then goes on to compute the (unique) spline which has this knot set and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has $(\theta)=S$. The routine computes the spline by an iterative scheme which is ended when $(\theta)=S$ within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF.

An exception occurs when the routine finds at the start that, even with no interior knots ($n=8$), the least-squares spline

already has its weighted sum of squares of residuals $\leq S$. In this case, since this spline (which is simply a cubic polynomial) also has an optimal value for the smoothness measure (η), namely zero, it is returned at once as the (trivial) solution. It will usually mean that S has been chosen too large.

For further details of the algorithm and its use, see Dierckx [3]

8.4. Evaluation of Computed Spline

The value of the computed spline at a given value X may be obtained in the double precision variable S by the call:

```
CALL EO2BBF(N,LAMDA,C,X,S,IFAIL)
```

where N , $LAMDA$ and C are the output parameters of EO2BEF.

The values of the spline and its first three derivatives at a given value X may be obtained in the double precision array $SDIF$ of dimension at least 4 by the call:

```
CALL EO2BCF(N,LAMDA,C,X,LEFT,SDIF,IFAIL)
```

where if $LEFT = 1$, left-hand derivatives are computed and if $LEFT \neq 1$, right-hand derivatives are calculated. The value of $LEFT$ is only relevant if X is an interior knot.

The value of the definite integral of the spline over the interval $X(1)$ to $X(M)$ can be obtained in the double precision variable $SINT$ by the call:

```
CALL EO2BDF(N,LAMDA,C,SINT,IFAIL)
```

9. Example

This example program reads in a set of data values, followed by a set of values of S . For each value of S it calls EO2BEF to compute a spline approximation, and prints the values of the knots and the B-spline coefficients c .

i

The program includes code to evaluate the computed splines, by calls to EO2BBF, at the points x and at points mid-way between

r

them. These values are not printed out, however; instead the results are illustrated by plots of the computed splines, together with the data points (indicated by $*$) and the positions of the knots (indicated by vertical lines): the effect of decreasing S can be clearly seen. (The plots were obtained by

calling NAG Graphical Supplement routine J06FAF(*).)

Please see figures in printed Reference Manual

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02DAF
 E02DAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E02DAF forms a minimal, weighted least-squares bicubic spline surface fit with prescribed knots to a given set of data points.

2. Specification

```

      SUBROUTINE E02DAF (M, PX, PY, X, Y, F, W, LAMDA, MU,
1          POINT, NPOINT, DL, C, NC, WS, NWS, EPS,
2          SIGMA, RANK, IFAIL)
      INTEGER      M, PX, PY, POINT(NPOINT), NPOINT, NC, NWS,
1          RANK, IFAIL
      DOUBLE PRECISION X(M), Y(M), F(M), W(M), LAMDA(PX), MU(PY),
1          DL(NC), C(NC), WS(NWS), EPS, SIGMA

```

3. Description

This routine determines a bicubic spline fit $s(x,y)$ to the set of data points (x_r, y_r, f_r) with weights w_r , for $r=1,2,\dots,m$. The two sets of internal knots of the spline, $\{(\lambda_r)\}$ and $\{(\mu_r)\}$, associated with the variables x and y respectively, are prescribed by the user. These knots can be thought of as dividing the data region of the (x,y) plane into panels (see diagram in Section 5). A bicubic spline consists of a separate bicubic polynomial in each panel, the polynomials joining together with continuity up to the second derivative across the panel boundaries.

$s(x,y)$ has the property that (Sigma) , the sum of squares of its weighted residuals (ρ_r) , for $r=1,2,\dots,m$, where

$$\begin{aligned} & r \\ (\rho) = & w (s(x, y) - f), \\ & r \quad r \quad r \quad r \quad r \end{aligned} \tag{1}$$

is as small as possible for a bicubic spline with the given knot sets. The routine produces this minimized value of (Sigma) and the coefficients c_{ij} in the B-spline representation of $s(x, y)$ -

see Section 8. E02DEF and E02DFF are available to compute values of the fitted spline from the coefficients c_{ij} .

The least-squares criterion is not always sufficient to determine the bicubic spline uniquely: there may be a whole family of splines which have the same minimum sum of squares. In these cases, the routine selects from this family the spline for which the sum of squares of the coefficients c_{ij} is smallest: in other

words, the minimal least-squares solution. This choice, although arbitrary, reduces the risk of unwanted fluctuations in the spline fit. The method employed involves forming a system of m linear equations in the coefficients c_{ij} and then computing its

least-squares solution, which will be the minimal least-squares solution when appropriate. The basis of the method is described in Hayes and Halliday [4]. The matrix of the equation is formed using a recurrence relation for B-splines which is numerically stable (see Cox [1] and de Boor [2] - the former contains the more elementary derivation but, unlike [2], does not cover the case of coincident knots). The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotation (see Gentleman [3]). This requires only one row of the matrix to be stored at a time. Advantage is taken of the stepped-band structure which the matrix possesses when the data points are suitably ordered, there being at most sixteen non-zero elements in any row because of the definition of B-splines. First the matrix is reduced to upper triangular form and then the diagonal elements of this triangle are examined in turn. When an element is encountered whose square, divided by the mean squared weight, is less than a threshold (epsilon), it is replaced by zero and the rest of the elements in its row are reduced to zero by rotations with the remaining rows. The rank of the system is taken to be the number of non-zero diagonal elements in the final triangle, and the non-zero rows of this triangle are used to compute the minimal least-squares solution. If all the diagonal elements are non-zero, the rank is equal to the number of coefficients c_{ij} and the solution

obtained is the ordinary least-squares solution, which is unique

in this case.

5. Parameters

- 1: M -- INTEGER Input
On entry: the number of data points, m. Constraint: $M > 1$.
- 2: PX -- INTEGER Input
- 3: PY -- INTEGER Input
On entry: the total number of knots (λ) and (μ) associated with the variables x and y, respectively.
Constraint: $PX \geq 8$ and $PY \geq 8$.

(They are such that $PX-8$ and $PY-8$ are the corresponding numbers of interior knots.) The running time and storage required by the routine are both minimized if the axes are labelled so that PY is the smaller of PX and PY.

- 4: X(M) -- DOUBLE PRECISION array Input
- 5: Y(M) -- DOUBLE PRECISION array Input
- 6: F(M) -- DOUBLE PRECISION array Input
On entry: the co-ordinates of the data point (x_r, y_r, f_r) , for $r=1,2,\dots,m$. The order of the data points is immaterial, but see the array POINT, below.
- 7: W(M) -- DOUBLE PRECISION array Input
On entry: the weight w_r of the rth data point. It is important to note the definition of weight implied by the equation (1) in Section 3, since it is also common usage to

define weight as the square of this weight. In this routine, each w_r should be chosen inversely proportional to the

(absolute) accuracy of the corresponding f_r , as expressed, for example, by the standard deviation or probable error of the f_r . When the f_r are all of the same accuracy, all the w_r may be set equal to 1.0.

- 8: LAMDA(PX) -- DOUBLE PRECISION array Input/Output
 On entry: LAMDA(i+4) must contain the i th interior knot
 (lambda) associated with the variable x , for $i=1,2,\dots,PX-8$. The knots must be in non-decreasing order and lie strictly within the range covered by the data values of x . A knot is a value of x at which the spline is allowed to be discontinuous in the third derivative with respect to x , though continuous up to the second derivative. This degree of continuity can be reduced, if the user requires, by the use of coincident knots, provided that no more than four knots are chosen to coincide at any point. Two, or three, coincident knots allow loss of continuity in, respectively, the second and first derivative with respect to x at the value of x at which they coincide. Four coincident knots split the spline surface into two independent parts. For choice of knots see Section 8. On exit: the interior knots LAMDA(5) to LAMDA(PX-4) are unchanged, and the segments LAMDA(1:4) and LAMDA(PX-3:PX) contain additional (exterior) knots introduced by the routine in order to define the full set of B-splines required. The four knots in the first segment are all set equal to the lowest data value of x and the other four additional knots are all set equal to the highest value: there is experimental evidence that coincident end-knots are best for numerical accuracy. The complete array must be left undisturbed if E02DEF or E02DFF is to be used subsequently.
- 9: MU(PY) -- DOUBLE PRECISION array Input
 On entry: MU(i+4) must contain the i th interior knot (μ) associated with the variable y , $i=1,2,\dots,PY-8$. The same remarks apply to MU as to LAMDA above, with Y replacing X , and y replacing x .
- 10: POINT(NPOINT) -- INTEGER array Input
 On entry: indexing information usually provided by E02ZAF which enables the data points to be accessed in the order which produces the advantageous matrix structure mentioned in Section 3. This order is such that, if the (x,y) plane is

thought of as being divided into rectangular panels by the two sets of knots, all data in a panel occur before data in succeeding panels, where the panels are numbered from bottom to top and then left to right with the usual arrangement of axes, as indicated in the diagram.

Please see figure in printed Reference Manual

A data point lying exactly on one or more panel sides is considered to be in the highest numbered panel adjacent to the point. E02ZAF should be called to obtain the array POINT, unless it is provided by other means.

- | | | |
|-----|--|-----------|
| 11: | NPOINT -- INTEGER | Input |
| | On entry:
the dimension of the array POINT as declared in the (sub)program from which E02DAF is called.
Constraint: NPOINT >= M + (PX-7)*(PY-7). | |
| 12: | DL(NC) -- DOUBLE PRECISION array | Output |
| | On exit: DL gives the squares of the diagonal elements of the reduced triangular matrix, divided by the mean squared weight. It includes those elements, less than (epsilon), which are treated as zero (see Section 3). | |
| 13: | C(NC) -- DOUBLE PRECISION array | Output |
| | On exit: C gives the coefficients of the fit. C((PY-4)*(i-1)+j) is the coefficient c_{ij} of Section 3 and Section 8 for $i=1,2,\dots,PX-4$ and $j=1,2,\dots,PY-4$. These coefficients are used by E02DEF or E02DFF to calculate values of the fitted function. | |
| 14: | NC -- INTEGER | Input |
| | On entry: the value (PX-4)*(PY-4). | |
| 15: | WS(NWS) -- DOUBLE PRECISION array | Workspace |
| 16: | NWS -- INTEGER | Input |
| | On entry:
the dimension of the array WS as declared in the (sub)program from which E02DAF is called.
Constraint: NWS >= (2*NC+1)*(3*PY-6)-2. | |
| 17: | EPS -- DOUBLE PRECISION | Input |
| | On entry: a threshold (epsilon) for determining the effective rank of the system of linear equations. The rank is determined as the number of elements of the array DL (see below) which are non-zero. An element of DL is regarded as zero if it is less than (epsilon). Machine precision is a | |

suitable value for (epsilon) in most practical applications which have only 2 or 3 decimals accurate in data. If some coefficients of the fit prove to be very large compared with the data ordinates, this suggests that (epsilon) should be increased so as to decrease the rank. The array DL will give a guide to appropriate values of (epsilon) to achieve this, as well as to the choice of (epsilon) in other cases where some experimentation may be needed to determine a value which leads to a satisfactory fit.

- 18: SIGMA -- DOUBLE PRECISION Output
 On exit: (Sigma), the weighted sum of squares of residuals. This is not computed from the individual residuals but from the right-hand sides of the orthogonally-transformed linear equations. For further details see Hayes and Halliday [4] page 97. The two methods of computation are theoretically equivalent, but the results may differ because of rounding error.
- 19: RANK -- INTEGER Output
 On exit: the rank of the system as determined by the value of the threshold (epsilon). When RANK = NC, the least-squares solution is unique: in other cases the minimal least-squares solution is computed.
- 20: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

- IFAIL= 1
 At least one set of knots is not in non-decreasing order, or an interior knot is outside the range of the data values.
- IFAIL= 2
 More than four knots coincide at a single point, possibly because all data points have the same value of x (or y) or because an interior knot coincides with an extreme data value.
- IFAIL= 3
 Array POINT does not indicate the data points in panel order. Call EO2ZAF to obtain a correct array.

IFAIL= 4

On entry M <= 1,

or PX < 8,

or PY < 8,

or NC /= (PX-4)*(PY-4),

or NWS is too small,

or NPOINT is too small.

IFAIL= 5

All the weights w_r are zero or rank determined as zero.

7. Accuracy

The computation of the B-splines and reduction of the observation matrix to triangular form are both numerically stable.

8. Further Comments

The time taken by this routine is approximately proportional to m^2 the number of data points, m , and to $(3*(PY-4)+4)$.

The B-spline representation of the bicubic spline is

$$s(x,y) = \sum_{ij} c_{ij} M_i(x) N_j(y)$$

summed over $i=1,2,\dots,PX-4$ and over $j=1,2,\dots,PY-4$. Here $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots $(\lambda_i), (\lambda_{i+1}), \dots, (\lambda_{i+4})$ and the latter on the knots $(\mu_j), (\mu_{j+1}), \dots, (\mu_{j+4})$. For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [2] for normalised B-splines.

The choice of the interior knots, which help to determine the spline's shape, must largely be a matter of trial and error. It is usually best to start with a small number of knots and,

examining the fit at each stage, add a few knots at a time at places where the fit is particularly poor. In intervals of x or y where the surface represented by the data changes rapidly, in function value or derivatives, more knots will be needed than elsewhere. In some cases guidance can be obtained by analogy with the case of coincident knots: for example, just as three coincident knots can produce a discontinuity in slope, three close knots can produce rapid change in slope. Of course, such rapid changes in behaviour must be adequately represented by the data points, as indeed must the behaviour of the surface generally, if a satisfactory fit is to be achieved. When there is no rapid change in behaviour, equally-spaced knots will often suffice.

In all cases the fit should be examined graphically before it is accepted as satisfactory.

The fit obtained is not defined outside the rectangle

$$\begin{array}{ccccc} (\lambda) & \leq x \leq (\lambda) & , & (\mu) & \leq y \leq (\mu) \\ 4 & & \text{PX-3} & 4 & \text{PY-3} \end{array}$$

The reason for taking the extreme data values of x and y for these four knots is that, as is usual in data fitting, the fit cannot be expected to give satisfactory values outside the data region. If, nevertheless, the user requires values over a larger rectangle, this can be achieved by augmenting the data with two artificial data points $(a,c,0)$ and $(b,d,0)$ with zero weight, where $a \leq x \leq b$, $c \leq y \leq d$ defines the enlarged rectangle. In the case when the data are adequate to make the least-squares solution unique ($\text{RANK} = \text{NC}$), this enlargement will not affect the fit over the original rectangle, except for possibly enlarged rounding errors, and will simply continue the bicubic polynomials in the panels bordering the rectangle out to the new boundaries: in other cases the fit will be affected. Even using the original rectangle there may be regions within it, particularly at its corners, which lie outside the data region and where, therefore, the fit will be unreliable. For example, if there is no data point in panel 1 of the diagram in Section 5, the least-squares criterion leaves the spline indeterminate in this panel: the minimal spline determined by the subroutine in this case passes through the value zero at the point $((\lambda), (\mu))$.

4 4

9. Example

This example program reads a value for (ϵ) , and a set of data points, weights and knot positions. If there are more y knots than x knots, it interchanges the x and y axes. It calls E02ZAF to sort the data points into panel order, E02DAF to fit a

bicubic spline to them, and E02DEF to evaluate the spline at the data points.

Finally it prints:

```

the weighted sum of squares of residuals computed from the
linear equations;

the rank determined by E02DAF;

data points, fitted values and residuals in panel order;

the weighted sum of squares of the residuals;

the coefficients of the spline fit.
```

The program is written to handle any number of data sets.

Note: the data supplied in this example is not typical of a realistic problem: the number of data points would normally be much larger (in which case the array dimensions and the value of NWS in the program would have to be increased); and the value of (epsilon) would normally be much smaller on most machines (see

-6

Section 5; the relatively large value of 10 has been chosen in order to illustrate a minimal least-squares solution when RANK < NC; in this example NC = 24).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

      INTEGER      MX, MY, NXEST, NYEST, NX, NY, LWRK, IWRK
1          (LIWRK), LIWRK, IFAIL
      DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), S, LAMDA(NXEST),
1          MU(NYEST), C((NXEST-4)*(NYEST-4)), FP, WRK
2          (LWRK)
      CHARACTER*1   START

```

3. Description

This routine determines a smooth bicubic spline approximation $s(x,y)$ to the set of data points $(x_q, y_r, f_{q,r})$, for $q=1,2,\dots,m$ and $r=1,2,\dots,m$.

The spline is given in the B-spline representation

$$s(x,y) = \sum_{i=1}^{n-4} \sum_{j=1}^{n-4} c_{ij} M_i(x) N_j(y), \quad (1)$$

where $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots (λ_1) to (λ_{i+4}) and the latter on the knots (μ_1) to (μ_{j+4}) . For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers n_x and n_y of these knots and their values $(\lambda_1), \dots, (\lambda_{n_x})$ and $(\mu_1), \dots, (\mu_{n_y})$ are chosen automatically by the routine. The knots $(\lambda_5), \dots, (\lambda_{n_x-4})$ and $(\mu_5), \dots, (\mu_{n_y-4})$ are the interior knots; they divide the approximation domain $[x_1, x_m] \times [y_1, y_m]$ into (

$n-7$ subpanels $[(\lambda_{ij}^m), (\lambda_{ij+1,j+1}^m)] * [(\mu_{ij}^m), (\mu_{ij+1,j+1}^m)]$,
 for $i=4,5,\dots,n-4$, $j=4,5,\dots,n-4$. Then, much as in the curve
 case (see E02BEF), the coefficients c_{ij}^x are determined as the
 solution of the following constrained minimization problem:

minimize

$$(\eta), \quad (2)$$

subject to the constraint

$$\begin{aligned}
 & \sum_{q=1}^m \sum_{r=1}^m (\theta_{q,r})^2 \leq S, \\
 & q=1 \quad r=1
 \end{aligned} \quad (3)$$

where (η) is a measure of the (lack of) smoothness of $s(x,y)$.
 Its value depends on the discontinuity jumps in
 $s(x,y)$ across the boundaries of the subpanels. It is
 zero only when there are no discontinuities and is
 positive otherwise, increasing with the size of the
 jumps (see Dierckx [2] for details).

$(\epsilon)_{q,r}$ denotes the residual $f_{q,r} - s(x_{q,r}, y_{q,r})$,

and S is a non-negative number to be specified by the user.

By means of the parameter S , 'the smoothing factor', the user
 will then control the balance between smoothness and closeness of
 fit, as measured by the sum of squares of residuals in (3). If S
 is too large, the spline will be too smooth and signal will be
 lost (underfit); if S is too small, the spline will pick up too
 much noise (overfit). In the extreme cases the routine will
 return an interpolating spline $((\theta)=0)$ if S is set to zero,
 and the least-squares bicubic polynomial $((\eta)=0)$ if S is set
 very large. Experimenting with S -values between these two
 extremes should result in a good compromise. (See Section 8.3 for
 advice on choice of S .)

The method employed is outlined in Section 8.5 and fully
 described in Dierckx [2] and [3]. It involves an adaptive
 strategy for locating the knots of the bicubic spline (depending
 on the function underlying the data and on the value of S), and

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

3: X(MX) -- DOUBLE PRECISION array Input
 On entry: X(q) must be set to x , the x co-ordinate of the
q

qth grid point along the x axis, for $q=1,2,\dots,m$.

x

Constraint: $x_1 < x_2 < \dots < x_m$.

1 2 m
x

4: MY -- INTEGER Input
On entry: m , the number of grid points along the y axis.

y

Constraint: MY $\geq$ 4.

5: Y(MY) -- DOUBLE PRECISION array Input

On entry: Y(r) must be set to y , the y co-ordinate of the

r

rth grid point along the y axis, for $r=1,2,\dots,m$.

y

Constraint: $y_1 < y_2 < \dots < y_m$.

1 2 m
y

6: F(MX*MY) -- DOUBLE PRECISION array Input

On entry: F(m *(q-1)+r) must contain the data value f ,

y

q,r

for $q=1,2,\dots,m$ and $r=1,2,\dots,m$.

x

y

7: S -- DOUBLE PRECISION Input

On entry: the smoothing factor, S.

If S=0.0, the routine returns an interpolating spline.

If S is smaller than machine precision, it is assumed equal to zero.

For advice on the choice of S, see Section 3 and Section 8.3

Constraint: S $\geq$ 0.0.

8: NXEST -- INTEGER Input

9: NYEST -- INTEGER Input

On entry: an upper bound for the number of knots n_x and n_y

x y

required in the x- and y-directions respectively.

In most practical situations, NXEST =m_x/2 and NYEST =m_y/2 is

x

y

sufficient. NXEST and NYEST never need to be larger than

m_x+4 and m_y+4 respectively, the numbers of knots needed for

x

y

interpolation (S=0.0). See also Section 8.4. Constraint:

$NXEST \geq 8$ and $NYEST \geq 8$.

- 10: NX -- INTEGER Input/Output
 On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots, n , of the computed spline with respect to the x variable.
- 11: $LAMDA(NXEST)$ -- DOUBLE PRECISION array Input/Output
 On entry: if the warm start option is used, the values $LAMDA(1)$, $LAMDA(2)$, ..., $LAMDA(NX)$ must be left unchanged from the previous call. On exit: $LAMDA$ contains the complete set of knots (λ_i) associated with the x variable, the interior knots $LAMDA(5)$, $LAMDA(6)$, ..., $LAMDA(NX-4)$ as well as the additional knots $LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = X(1)$ and $LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) = LAMDA(NX) = X(MX)$ needed for the B-spline representation.
- 12: NY -- INTEGER Input/Output
 On entry: if the warm start option is used, the value of NY must be left unchanged from the previous call. On exit: the total number of knots, n , of the computed spline with respect to the y variable.
- 13: $MU(NYEST)$ -- DOUBLE PRECISION array Input/Output
 On entry: if the warm start option is used, the values $MU(1)$, $MU(2)$, ..., $MU(NY)$ must be left unchanged from the previous call. On exit: MU contains the complete set of knots (μ_i) associated with the y variable, the interior knots $MU(5)$, $MU(6)$, ..., $MU(NY-4)$ as well as the additional knots $MU(1) = MU(2) = MU(3) = MU(4) = Y(1)$ and $MU(NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = Y(MY)$ needed for the B-spline representation.
- 14: $C((NXEST-4)*(NYEST-4))$ -- DOUBLE PRECISION array Output
 On exit: the coefficients of the spline approximation. $C((n-4)*(i-1)+j)$ is the coefficient c_{ij} defined in Section 3.
- 15: FP -- DOUBLE PRECISION Output
 On exit: the sum of squared residuals, (θ), of the computed spline approximation. If $FP = 0.0$, this is an interpolating spline. FP should equal S within a relative tolerance of 0.001 unless $NX = NY = 8$, when the spline has no interior knots and so is simply a bicubic polynomial. For knots to be inserted, S must be set to a value below the

value of FP produced in this case.

- 16: WRK(LWRK) -- DOUBLE PRECISION array Workspace
 On entry: if the warm start option is used, the values WRK
 (1), ..., WRK(4) must be left unchanged from the previous
 call.

This array is used as workspace.

- 17: LWRK -- INTEGER Input
 On entry:
 the dimension of the array WRK as declared in the
 (sub)program from which E02DCF is called.
 Constraint:

$$\text{LWRK} \geq 4 * (\text{MX} + \text{MY}) + 11 * (\text{NXEST} + \text{NYEST}) + \text{NXEST} * \text{MY}$$

$$+ \max(\text{MY}, \text{NXEST}) + 54.$$

- 18: IWRK(LIWRK) -- INTEGER array Workspace
 On entry: if the warm start option is used, the values IWRK
 (1), ..., IWRK(3) must be left unchanged from the previous
 call.

This array is used as workspace.

- 19: LIWRK -- INTEGER Input
 On entry:
 the dimension of the array IWRK as declared in the
 (sub)program from which E02DCF is called.
 Constraint: $\text{LIWRK} \geq 3 + \text{MX} + \text{MY} + \text{NXEST} + \text{NYEST}.$

- 20: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry START /= 'C' or 'W',

or $\text{MX} < 4,$

```

or      MY < 4,

or      S < 0.0,

or      S = 0.0 and NXEST < MX + 4,

or      S = 0.0 and NYEST < MY + 4,

or      NXEST < 8,

or      NYEST < 8,

or      LWRK < 4*(MX+MY)+11*(NXEST+NYEST)+NXEST*MY+
           +max(MY,NXEST)+54

or      LIWRK < 3 + MX + MY + NXEST + NYEST.

```

IFAIL= 2

The values of $X(q)$, for $q = 1, 2, \dots, MX$, are not in strictly increasing order.

IFAIL= 3

The values of $Y(r)$, for $r = 1, 2, \dots, MY$, are not in strictly increasing order.

IFAIL= 4

The number of knots required is greater than allowed by NXEST and NYEST. Try increasing NXEST and/or NYEST and, if necessary, supplying larger arrays for the parameters LAMDA, MU, C, WRK and IWRK. However, if NXEST and NYEST are already large, say $NXEST > MX/2$ and $NYEST > MY/2$, then this error exit may indicate that S is too small.

IFAIL= 5

The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) -- perhaps by only a small amount, however.

7. Accuracy

On successful exit, the approximation returned is such that its sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if $n = 8$ and $n = 8$, FP may be significantly less than S: in this case

x y
 the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, a spline with no interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02DCF depends on the complexity of the shape of the data, the value of the smoothing factor S , and the number of data points. If E02DCF is to be called for different values of S , much time can be saved by setting $START =$

8.2. Weighting of Data Points

E02DCF does not allow individual weighting of the data values. If these were determined to widely differing accuracies, it may be better to use E02DDF. The computation time would be very much longer, however.

8.3. Choice of S

If the standard deviation of f is the same for all q and r
 q, r

(the case for which this routine is designed - see Section 8.2.) and known to be equal, at least approximately, to (σ) , say, then following Reinsch [5] and choosing the smoothing factor S in
 2

the range $(\sigma)(m + \sqrt{2}m)$, where $m = m$ m , is likely to give a
 x y

good start in the search for a satisfactory value. If the standard deviations vary, the sum of their squares over all the data points could be used. Otherwise experimenting with different values of S will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for S and so determine the least-squares bicubic polynomial; the value returned for FP , call it FP , gives an upper bound for S .
 0

Then progressively decrease the value of S to obtain closer fits - say by a factor of 10 in the beginning, $S = FP / 10$,
 0

$S = FP / 100$, and so on, and more carefully as the approximation
 0

shows more details.

The number of knots of the spline returned, and their location,

generally depend on the value of S and on the behaviour of the function underlying the data. However, if E02DCF is called with $START = 'W'$, the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of S and $START = 'W'$, a fit can finally be accepted as satisfactory, it may be worthwhile to call E02DCF once more with the selected value for S but now using $START = 'C'$. Often, E02DCF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

8.4. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds NXEST and NYEST. Indeed, if at a certain stage in E02DCF the number of knots in one direction (say n) has reached the value of its

x

upper bound (NXEST), then from that moment on all subsequent knots are added in the other (y) direction. Therefore the user has the option of limiting the number of knots the routine locates in any direction. For example, by setting $NXEST = 8$ (the lowest allowable value for NXEST), the user can indicate that he wants an approximation which is a simple cubic polynomial in the variable x .

8.5. Outline of Method Used

If $S=0$, the requisite number of knots is known in advance, $n = m + 4$ and $n = m + 4$; the interior knots are located immediately

$$x_i = x_{i-2} \quad \text{and} \quad y_j = y_{j-2}, \quad \text{for } i=5,6,\dots,n-4 \text{ and } j=5,6,\dots,n-4.$$

The corresponding least-squares spline is then an interpolating spline and therefore a solution of the problem.

If $S>0$, suitable knot sets are built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a bicubic spline is fitted to the data by least-squares, and (θ) , the sum of squares of residuals, is computed. If $(\theta)>S$, new knots are added to one knot set or the other so as to reduce (θ) at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of S and on the progress made so far in reducing (θ) . Sooner or later, we find that $(\theta)\leq S$ and at that point the knot sets are accepted. The routine then goes on to compute the (unique) spline which has these knot sets and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has $(\theta)=S$. The routine computes

the spline by an iterative scheme which is ended when $(\text{theta})=S$ within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF for least-squares curve fitting.

An exception occurs when the routine finds at the start that, even with no interior knots ($n=n=8$), the least-squares spline

x y

already has its sum of residuals $\leq S$. In this case, since this spline (which is simply a bicubic polynomial) also has an optimal value for the smoothness measure (η), namely zero, it is returned at once as the (trivial) solution. It will usually mean that S has been chosen too large.

For further details of the algorithm and its use see Dierckx [2].

8.6. Evaluation of Computed Spline

The values of the computed spline at the points $(TX(r), TY(r))$, for $r = 1, 2, \dots, N$, may be obtained in the double precision array FF, of length at least N , by the following code:

```
IFAIL = 0
CALL E02DEF(N,NX,NY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where NX , NY , $LAMDA$, MU and C are the output parameters of E02DCF, WRK is a double precision workspace array of length at least $NY-4$, and $IWRK$ is an integer workspace array of length at least $NY-4$.

To evaluate the computed spline on a KX by KY rectangular grid of points in the x - y plane, which is defined by the x co-ordinates stored in $TX(q)$, for $q=1, 2, \dots, KX$, and the y co-ordinates stored in $TY(r)$, for $r=1, 2, \dots, KY$, returning the results in the double precision array FG which is of length at least $KX \times KY$, the following call may be used:

```
IFAIL = 0
CALL E02DFF(KX,KY,NX,NY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
*          IWRK,LIWRK,IFAIL)
```

where NX , NY , $LAMDA$, MU and C are the output parameters of E02DCF, WRK is a double precision workspace array of length at least $LWRK = \min(NWRK1, NWRK2)$, $NWRK1 = KX \times 4 + NX$, $NWRK2 = KY \times 4 + NY$, and $IWRK$ is an integer workspace array of length at least $LIWRK = KY + NY - 4$ if $NWRK1 \geq NWRK2$, or $KX + NX - 4$ otherwise. The result of the spline evaluated at grid point (q, r) is returned in element $(KY \times (q-1) + r)$ of the array FG .

9. Example

This example program reads in values of MX , MY , x , for $q = 1, 2, \dots$
 q
 r
 ordinates f defined at the grid points (x, y) . It then calls
 q, r q, r
 E02DCF to compute a bicubic spline approximation for one
 specified value of S , and prints the values of the computed knots
 and B-spline coefficients. Finally it evaluates the spline at a
 small sample of points on a rectangular grid.

The example program is not reproduced here. The source code for
 all example programs is distributed with the NAG Foundation
 Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02DDF
 E02DDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
 your implementation to check implementation-dependent details.
 The symbol (*) after a NAG routine name denotes a routine that is
 not included in the Foundation Library.

1. Purpose

E02DDF computes a bicubic spline approximation to a set of
 scattered data. The knots of the spline are located
 automatically, but a single parameter must be specified to
 control the trade-off between closeness of fit and smoothness of
 fit.

2. Specification

```

      SUBROUTINE E02DDF (START, M, X, Y, F, W, S, NXEST, NYEST,
1          NX, LAMDA, NY, MU, C, FP, RANK, WRK,
2          LWRK, IWRK, LIWRK, IFAIL)
      INTEGER      M, NXEST, NYEST, NX, NY, RANK, LWRK, IWRK
1          (LIWRK), LIWRK, IFAIL
      DOUBLE PRECISION X(M), Y(M), F(M), W(M), S, LAMDA(NXEST),
1          MU(NYEST), C((NXEST-4)*(NYEST-4)), FP, WRK
2          (LWRK)
      CHARACTER*1   START
```

3. Description

This routine determines a smooth bicubic spline approximation
 $s(x, y)$ to the set of data points (x, y, f) with weights w , for

$r \quad r \quad r \quad r$

$r=1,2,\dots,m.$

The approximation domain is considered to be the rectangle $[x_{\min}, x_{\max}] \times [y_{\min}, y_{\max}]$, where $x_{\min}$ ($y_{\min}$) and $x_{\max}$ ($y_{\max}$) denote the lowest and highest data values of x (y).

The spline is given in the B-spline representation

$$s(x,y) = \sum_{i=1}^{n-4} \sum_{j=1}^{n-4} c_{ij} M_i(x) N_j(y), \quad (1)$$

where $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots (λ_1) to (λ_{i+4}) and the latter on the knots (μ_1) to (μ_{j+4}) . For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers n_x and n_y of these knots and their values $(\lambda_1), \dots, (\lambda_{n_x})$ and $(\mu_1), \dots, (\mu_{n_y})$ are chosen automatically by the routine. The knots $(\lambda_5), \dots, (\lambda_{n_x-4})$ and $(\mu_5), \dots, (\mu_{n_y-4})$ are the interior knots; they divide the approximation domain $[x_{\min}, x_{\max}] \times [y_{\min}, y_{\max}]$ into $(n_x-7) \times (n_y-7)$ subpanels $[(\lambda_i), (\lambda_{i+1})] \times [(\mu_j), (\mu_{j+1})]$, for $i=4,5,\dots,n_x-4$; $j=4,5,\dots,n_y-4$. Then, much as in the curve case (see E02BEF), the coefficients c_{ij} are determined as the solution of the following constrained minimization problem:

minimize

$$(\eta), \quad (2)$$

subject to the constraint

$$\begin{aligned} & \int_{r=1}^m (\text{theta})^2 (\text{epsilon})^2 \leq S \\ & \text{r}=1 \end{aligned} \quad (3)$$

where: (eta) is a measure of the (lack of) smoothness of $s(x,y)$. Its value depends on the discontinuity jumps in $s(x,y)$ across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

$(\text{epsilon})_r$ denotes the weighted residual $w_r(f - s(x,y))$,

and S is a non-negative number to be specified by the user.

By means of the parameter S , 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If S is too large, the spline will be too smooth and signal will be lost (underfit); if S is too small, the spline will pick up too much noise (overfit). In the extreme cases the method would return an interpolating spline ($(\text{theta})=0$) if S were set to zero, and returns the least-squares bicubic polynomial ($(\text{eta})=0$) if S is set very large. Experimenting with S -values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of S .) Note however, that this routine, unlike E02BEF and E02DCF, does not allow S to be set exactly to zero: to compute an interpolant to scattered data, E01SAF or E01SEF should be used.

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

5. Parameters

1: START -- CHARACTER*1 Input
 On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU or WRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU and WRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

2: M -- INTEGER Input
 On entry: m, the number of data points.

The number of data points with non-zero weight (see W below) must be at least 16.

3: X(M) -- DOUBLE PRECISION array Input

4: Y(M) -- DOUBLE PRECISION array Input

5: F(M) -- DOUBLE PRECISION array Input
 On entry: X(r), Y(r), F(r) must be set to the co-ordinates of (x_r, y_r, f_r), the rth data point, for r=1,2,...,m. The order of the data points is immaterial.

6: W(M) -- DOUBLE PRECISION array Input

On entry: $W(r)$ must be set to w_r , the r th value in the set of weights, for $r=1,2,\dots,m$. Zero weights are permitted and the corresponding points are ignored, except when determining $x_{\min}$, $x_{\max}$, $y_{\min}$ and $y_{\max}$ (see Section 8.4). For advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint: the number of data points with non-zero weight must be at least 16.

7: S -- DOUBLE PRECISION Input
On entry: the smoothing factor, S.

For advice on the choice of S, see Section 3 and Section 8.2.
Constraint: $S > 0.0$.

8: NXEST -- INTEGER Input

9: NYEST -- INTEGER Input
On entry: an upper bound for the number of knots n_x and n_y required in the x- and y-directions respectively.

In most practical situations, $NXEST = NYEST = 4 + \sqrt{m/2}$ is sufficient. See also Section 8.3. Constraint: $NXEST \geq 8$ and $NYEST \geq 8$.

10: NX -- INTEGER Input/Output
On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots, n_x , of the computed spline with respect to the x variable.

11: LAMDA(NXEST) -- DOUBLE PRECISION array Input/Output
On entry: if the warm start option is used, the values LAMDA(1), LAMDA(2), ..., LAMDA(NX) must be left unchanged from the previous call. On exit: LAMDA contains the complete set of knots (λ_i) associated with the x variable, the interior knots LAMDA(5), LAMDA(6), ..., LAMDA(NX-4) as well as the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = $x_{\min}$ and LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) = $x_{\max}$ needed for the B-spline representation (where $x_{\min}$ and $x_{\max}$ are as described in Section 3).

- 12: NY -- INTEGER Input/Output
 On entry: if the warm start option is used, the value of NY must be left unchanged from the previous call. On exit: the total number of knots, n , of the computed spline with respect to the y variable.
- 13: MU(NYEST) -- DOUBLE PRECISION array Input/Output
 On entry: if the warm start option is used, the values MU(1) MU(2), ..., MU(NY) must be left unchanged from the previous call. On exit: MU contains the complete set of knots (μ_i) associated with the y variable, the interior knots MU(5), MU(6), ..., MU(NY-4) as well as the additional knots MU(1) = MU(2) = MU(3) = MU(4) = $y_{\min}$ and MU(NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = $y_{\max}$ needed for the B-spline representation (where $y_{\min}$ and $y_{\max}$ are as described in Section 3).
- 14: C((NXEST-4)*(NYEST-4)) -- DOUBLE PRECISION array Output
 On exit: the coefficients of the spline approximation. C((n-4)*(i-1)+j) is the coefficient c_{ij} defined in Section 3.
- 15: FP -- DOUBLE PRECISION Output
 On exit: the weighted sum of squared residuals, (theta), of the computed spline approximation. FP should equal S within a relative tolerance of 0.001 unless NX = NY = 8, when the spline has no interior knots and so is simply a bicubic polynomial. For knots to be inserted, S must be set to a value below the value of FP produced in this case.
- 16: RANK -- INTEGER Output
 On exit: RANK gives the rank of the system of equations used to compute the final spline (as determined by a suitable machine-dependent threshold). When RANK = (NX-4)*(NY-4), the solution is unique; otherwise the system is rank-deficient and the minimum-norm solution is computed. The latter case may be caused by too small a value of S.
- 17: WRK(LWRK) -- DOUBLE PRECISION array Workspace
 On entry: if the warm start option is used, the value of WRK(1) must be left unchanged from the previous call.
 This array is used as workspace.
- 18: LWRK -- INTEGER Input

On entry:
the dimension of the array WRK as declared in the
(sub)program from which E02DDF is called.
Constraint: $LWRK \geq (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*w+56$,

where

$u = NXEST-4$, $v = NYEST-4$, and $w = \max(u, v)$.

For some problems, the routine may need to compute the minimal least-squares solution of a rank-deficient system of linear equations (see Section 3). The amount of workspace required to solve such problems will be larger than specified by the value given above, which must be increased by an amount, LWRK2 say. An upper bound for LWRK2 is given by $4*u*v*w+2*u*v+4*w$, where u , v and w are as above. However, if there are enough data points, scattered uniformly over the approximation domain, and if the smoothing factor S is not too small, there is a good chance that this extra workspace is not needed. A lot of memory might therefore be saved by assuming $LWRK2 = 0$.

19: IWRK(LIWRK) -- INTEGER array Workspace

20: LIWRK -- INTEGER Input

On entry:
the dimension of the array IWRK as declared in the
(sub)program from which E02DDF is called.
Constraint: $LIWRK \geq M+2*(NXEST-7)*(NYEST-7)$.

21: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry START /= 'C' or 'W',

or the number of data points with non-zero weight <

```

16,

or      S <= 0.0,

or      NXEST < 8,

or      NYEST < 8,

or      LWRK < (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*w+56,
          where u = NXEST - 4, v = NYEST - 4 and w=max(u,v),

or      LIWRK < M+2*(NXEST-7)*(NYEST-7).

```

IFAIL= 2
 On entry either all the $X(r)$, for $r = 1, 2, \dots, M$, are equal,
 or all the $Y(r)$, for $r = 1, 2, \dots, M$, are equal.

IFAIL= 3
 The number of knots required is greater than allowed by
 NXEST and NYEST. Try increasing NXEST and/or NYEST and, if
 necessary, supplying larger arrays for the parameters LAMDA,
 MU, C, WRK and IWRK. However, if NXEST and NYEST are already
 large, say $NXEST, NYEST > 4 + \sqrt{M/2}$, then this error exit
 may indicate that S is too small.

IFAIL= 4
 No more knots can be added because the number of B-spline
 coefficients $(NX-4)*(NY-4)$ already exceeds the number of
 data points M . This error exit may occur if either of S or M
 is too small.

IFAIL= 5
 No more knots can be added because the additional knot would
 (quasi) coincide with an old one. This error exit may occur
 if too large a weight has been given to an inaccurate data
 point, or if S is too small.

IFAIL= 6
 The iterative process used to compute the coefficients of
 the approximating spline has failed to converge. This error
 exit may occur if S has been set very small. If the error
 persists with increased S , consult NAG.

IFAIL= 7
 LWRK is too small; the routine needs to compute the minimal
 least-squares solution of a rank-deficient system of linear
 equations, but there is not enough workspace. There is no
 approximation returned but, having saved the information

contained in NX, LAMDA, NY, MU and WRK, and having adjusted the value of LWRK and the dimension of array WRK accordingly, the user can continue at the point the program was left by calling E02DDF with START = 'W'. Note that the requested value for LWRK is only large enough for the current phase of the algorithm. If the routine is restarted with LWRK set to the minimum value requested, a larger request may be made at a later stage of the computation. See Section 5 for the upper bound on LWRK. On soft failure, the minimum requested value for LWRK is returned in IWRK(1) and the safe value for LWRK is returned in IWRK(2).

If IFAIL = 3,4,5 or 6, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3 -- perhaps only by a small amount, however).

7. Accuracy

On successful exit, the approximation returned is such that its weighted sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if $n_x = 8$ and $n_y = 8$, FP may be significantly less than S: in

x y

this case the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, a spline with no interior knots.

8. Further Comments

8.1. Timing

The time taken for a call of E02DDF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02DDF is to be called for different values of S, much time can be saved by setting START = It should be noted that choosing S very small considerably increases computation time.

8.2. Choice of S

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of w_r would

r r
