SYNOPSIS
   Functions/Subroutines
       subroutine cla_geamv (TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
           INCY)
           CLA_GEAMV computes a matrix-vector product using a general matrix
           to calculate error bounds.

Function/Subroutine Documentation
   subroutine cla_geamv (integer TRANS, integer M, integer N, real ALPHA,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( * ) X,
       integer INCX, real BETA, real, dimension( * ) Y, integer INCY)
       CLA_GEAMV computes a matrix-vector product using a general matrix to
       calculate error bounds.

Purpose:
   CLA_GEAMV  performs one of the matrix-vector operations

               y := alpha*abs(A)*abs(x) + beta*abs(y),
          or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
```

```
  Unchanged on exit.

N
  N is INTEGER
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is REAL
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is COMPLEX array, dimension (LDA,n)
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least
  max( 1, m ).
  Unchanged on exit.

X
  X is COMPLEX array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is REAL array, dimension
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
```

```
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       real function cla_gercond_c (TRANS, N, A, LDA, AF, LDAF, IPIV, C,
           CAPPLY, INFO, WORK, RWORK)
           CLA_GERCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for general matrices.

Function/Subroutine Documentation
   real function cla_gercond_c (character TRANS, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF,
       integer LDAF, integer, dimension( * ) IPIV, real, dimension( * ) C,
       logical CAPPLY, integer INFO, complex, dimension( * ) WORK, real,
       dimension( * ) RWORK)
       CLA_GERCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for general matrices.

Purpose:
   CLA_GERCOND_C computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by CGETRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from the factorization A = P*L*U
   as computed by CGETRF; row i of the matrix was interchanged
   with row IPIV(i).

 C
   C is REAL array, dimension (N)
   The vector C in the formula op(A) * inv(diag(C)).

 CAPPLY
   CAPPLY is LOGICAL
   If .TRUE. then access the vector C in the formula above.

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
   WORK is COMPLEX array, dimension (2*N).
   Workspace.

 RWORK
   RWORK is REAL array, dimension (N).
   Workspace.
```

SYNOPSIS
   Functions/Subroutines
       real function cla_gercond_x (TRANS, N, A, LDA, AF, LDAF, IPIV, X, INFO,
           WORK, RWORK)
           CLA_GERCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for general matrices.

Function/Subroutine Documentation
   real function cla_gercond_x (character TRANS, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF,
       integer LDAF, integer, dimension( * ) IPIV, complex, dimension( * ) X,
       integer INFO, complex, dimension( * ) WORK, real, dimension( * ) RWORK)
       CLA_GERCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for general matrices.

Purpose:
```

```
   CLA_GERCOND_X computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by CGETRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from the factorization A = P*L*U
   as computed by CGETRF; row i of the matrix was interchanged
   with row IPIV(i).

 X
   X is COMPLEX array, dimension (N)
   The vector X in the formula op(A) * diag(X).

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
```

```
  WORK is COMPLEX array, dimension (2*N).
  Workspace.

RWORK
  RWORK is REAL array, dimension (N).
  Workspace.
```

       CLA_GERFSX_EXTENDED

Purpose:
   CLA_GERFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by CGERFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERRS_N
   and ERRS_C for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERRS_N and ERRS_C.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra
```

```
TRANS_TYPE
  TRANS_TYPE is INTEGER
  Specifies the transposition operation on A.
  The value is defined by ILATRANS(T) where T is a CHARACTER and
  T    = 'N':  No transpose
       = 'T':  Transpose
       = 'C':  Conjugate transpose

N
  N is INTEGER
  The number of linear equations, i.e., the order of the
  matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by CGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by CGETRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
```

```
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by CGETRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERRS_N
  and ERRS_C).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERRS_N
  ERRS_N is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                     max_j abs(X(j,i))
```

```
  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERRS_N(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_N(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*A, where S scales each row by a power of the
           radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field
  above.

ERRS_C
  ERRS_C is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERRS_C is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.
```

```
  The first index in ERRS_C(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_C(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*(A*diag(x)), where x is the solution for the
           current right-hand side and S scales each row of
           A*diag(x) by a power of the radix so all absolute row
           sums of Z are approximately 1.

This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is REAL array, dimension (N)
  Workspace.

DY
  DY is COMPLEX array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
```

```
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to CGETRS had an illegal value

====================================================================

SYNOPSIS
   Functions/Subroutines
       real function cla_gerpvgrw (N, NCOLS, A, LDA, AF, LDAF)
           CLA_GERPVGRW multiplies a square real matrix by a complex matrix.

Function/Subroutine Documentation
   real function cla_gerpvgrw (integer N, integer NCOLS, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF, integer
       LDAF)
       CLA_GERPVGRW multiplies a square real matrix by a complex matrix.

Purpose:
   CLA_GERPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by CGETRF.
```

```
 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctgevc (SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL,
           VR, LDVR, MM, M, WORK, RWORK, INFO)
           CTGEVC

Function/Subroutine Documentation
   subroutine ctgevc (character SIDE, character HOWMNY, logical, dimension( *
       ) SELECT, integer N, complex, dimension( lds, * ) S, integer LDS,
       complex, dimension( ldp, * ) P, integer LDP, complex, dimension( ldvl,
       * ) VL, integer LDVL, complex, dimension( ldvr, * ) VR, integer LDVR,
       integer MM, integer M, complex, dimension( * ) WORK, real, dimension( *
       ) RWORK, integer INFO)
       CTGEVC

Purpose:
```

```
   CTGEVC computes some or all of the right and/or left eigenvectors of
   a pair of complex matrices (S,P), where S and P are upper triangular.
   Matrix pairs of this type are produced by the generalized Schur
   factorization of a complex matrix pair (A,B):

      A = Q*S*Z**H,  B = Q*P*Z**H

   as computed by CGGHRD + CHGEQZ.

   The right eigenvector x and the left eigenvector y of (S,P)
   corresponding to an eigenvalue w are defined by:

      S*x = w*P*x,  (y**H)*S = w*(y**H)*P,

   where y**H denotes the conjugate tranpose of y.
   The eigenvalues are not input to this routine, but are computed
   directly from the diagonal elements of S and P.

   This routine returns the matrices X and/or Y of right and left
   eigenvectors of (S,P), or the products Z*X and/or Q*Y,
   where Z and Q are input matrices.
   If Q and Z are the unitary factors from the generalized Schur
   factorization of a matrix pair (A,B), then Z*X and Q*Y
   are the matrices of right and left eigenvectors of (A,B).

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'R': compute right eigenvectors only;
   = 'L': compute left eigenvectors only;
   = 'B': compute both right and left eigenvectors.

 HOWMNY
   HOWMNY is CHARACTER*1
   = 'A': compute all right and/or left eigenvectors;
   = 'B': compute all right and/or left eigenvectors,
          backtransformed by the matrices in VR and/or VL;
   = 'S': compute selected right and/or left eigenvectors,
          specified by the logical array SELECT.

 SELECT
   SELECT is LOGICAL array, dimension (N)
   If HOWMNY='S', SELECT specifies the eigenvectors to be
   computed.  The eigenvector corresponding to the j-th
   eigenvalue is computed if SELECT(j) = .TRUE..
   Not referenced if HOWMNY = 'A' or 'B'.

 N
   N is INTEGER
```

```
  The order of the matrices S and P.  N >= 0.

S
  S is COMPLEX array, dimension (LDS,N)
  The upper triangular matrix S from a generalized Schur
  factorization, as computed by CHGEQZ.

LDS
  LDS is INTEGER
  The leading dimension of array S.  LDS >= max(1,N).

P
  P is COMPLEX array, dimension (LDP,N)
  The upper triangular matrix P from a generalized Schur
  factorization, as computed by CHGEQZ.  P must have real diagonal elements.

LDP
  LDP is INTEGER
  The leading dimension of array P.  LDP >= max(1,N).

VL
  VL is COMPLEX array, dimension (LDVL,MM)
  On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must
  contain an N-by-N matrix Q (usually the unitary matrix Q
  of left Schur vectors returned by CHGEQZ).
  On exit, if SIDE = 'L' or 'B', VL contains:
  if HOWMNY = 'A', the matrix Y of left eigenvectors of (S,P);
  if HOWMNY = 'B', the matrix Q*Y;
  if HOWMNY = 'S', the left eigenvectors of (S,P) specified by
                   SELECT, stored consecutively in the columns of
                   VL, in the same order as their eigenvalues.
  Not referenced if SIDE = 'R'.

LDVL
  LDVL is INTEGER
  The leading dimension of array VL.  LDVL >= 1, and if
  SIDE = 'L' or 'l' or 'B' or 'b', LDVL >= N.

VR
  VR is COMPLEX array, dimension (LDVR,MM)
  On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must
  contain an N-by-N matrix Q (usually the unitary matrix Z
  of right Schur vectors returned by CHGEQZ).
  On exit, if SIDE = 'R' or 'B', VR contains:
  if HOWMNY = 'A', the matrix X of right eigenvectors of (S,P);
  if HOWMNY = 'B', the matrix Z*X;
  if HOWMNY = 'S', the right eigenvectors of (S,P) specified by
                   SELECT, stored consecutively in the columns of
                   VR, in the same order as their eigenvalues.
  Not referenced if SIDE = 'L'.
```

```
LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1, and if
  SIDE = 'R' or 'B', LDVR >= N.

MM
  MM is INTEGER
  The number of columns in the arrays VL and/or VR. MM >= M.

M
  M is INTEGER
  The number of columns in the arrays VL and/or VR actually
  used to store the eigenvectors.  If HOWMNY = 'A' or 'B', M
  is set to N.  Each selected eigenvector occupies one column.

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
   Functions/Subroutines
       subroutine ctgexc (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
           IFST, ILST, INFO)
           CTGEXC

Function/Subroutine Documentation
   subroutine ctgexc (logical WANTQ, logical WANTZ, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldb, * ) B,
```

```
      integer LDB, complex, dimension( ldq, * ) Q, integer LDQ, complex,
      dimension( ldz, * ) Z, integer LDZ, integer IFST, integer ILST, integer
      INFO)
      CTGEXC

Purpose:
   CTGEXC reorders the generalized Schur decomposition of a complex
   matrix pair (A,B), using an unitary equivalence transformation
   (A, B) := Q * (A, B) * Z**H, so that the diagonal block of (A, B) with
   row index IFST is moved to row ILST.

   (A, B) must be in generalized Schur canonical form, that is, A and
   B are both upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.

   Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
   Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the upper triangular matrix A in the pair (A, B).
   On exit, the updated matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is COMPLEX array, dimension (LDB,N)
   On entry, the upper triangular matrix B in the pair (A, B).
   On exit, the updated matrix B.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

Q
  Q is COMPLEX array, dimension (LDZ,N)
  On entry, if WANTQ = .TRUE., the unitary matrix Q.
  On exit, the updated matrix Q.
  If WANTQ = .FALSE., Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q. LDQ >= 1;
  If WANTQ = .TRUE., LDQ >= N.

Z
  Z is COMPLEX array, dimension (LDZ,N)
  On entry, if WANTZ = .TRUE., the unitary matrix Z.
  On exit, the updated matrix Z.
  If WANTZ = .FALSE., Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z. LDZ >= 1;
  If WANTZ = .TRUE., LDZ >= N.

IFST
  IFST is INTEGER

ILST
  ILST is INTEGER
  Specify the reordering of the diagonal blocks of (A, B).
  The block with row index IFST is moved to row ILST, by a
  sequence of swapping between adjacent blocks.

INFO
  INFO is INTEGER
  =0:  Successful exit.
  <0:  if INFO = -i, the i-th argument had an illegal value.
  =1:  The transformed matrix pair (A, B) would be too far
       from generalized Schur form; the problem is ill-
       conditioned. (A, B) may have been partially reordered,
       and ILST points to the first row of the current
       position of the block being moved.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgebak (JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
           ZGEBAK

Function/Subroutine Documentation
   subroutine zgebak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, double precision, dimension( * ) SCALE, integer M,
       complex*16, dimension( ldv, * ) V, integer LDV, integer INFO)
       ZGEBAK

Purpose:
   ZGEBAK forms the right or left eigenvectors of a complex general
   matrix by backward transformation on the computed eigenvectors of the
   balanced matrix output by ZGEBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N', do nothing, return immediately;
   = 'P', do backward transformation for permutation only;
   = 'S', do backward transformation for scaling only;
   = 'B', do backward transformations for both permutation and scaling.
   JOB must be the same as the argument JOB supplied to ZGEBAL.

 SIDE
   SIDE is CHARACTER*1
   = 'R':  V contains right eigenvectors;
   = 'L':  V contains left eigenvectors.

 N
   N is INTEGER
   The number of rows of the matrix V.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   The integers ILO and IHI determined by ZGEBAL.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 SCALE
```

```
  SCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutation and scaling factors, as returned by ZGEBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is COMPLEX*16 array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by ZHSEIN or ZTREVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the array V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgebal (JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
           ZGEBAL

Function/Subroutine Documentation
   subroutine zgebal (character JOB, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer ILO, integer IHI, double precision,
       dimension( * ) SCALE, integer INFO)
       ZGEBAL

Purpose:
   ZGEBAL balances a general complex matrix A.  This involves, first,
   permuting A by a similarity transformation to isolate eigenvalues
   in the first 1 to ILO-1 and last IHI+1 to N elements on the
   diagonal; and second, applying a diagonal similarity transformation
   to rows and columns ILO to IHI to make the rows and columns as
   close in norm as possible.  Both steps are optional.

   Balancing may reduce the 1-norm of the matrix, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A:
   = 'N':  none:  simply set ILO = 1, IHI = N, SCALE(I) = 1.0
           for i = 1,...,N;
```

```
  = 'P':  permute only;
  = 'S':  scale only;
  = 'B':  both permute and scale.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the input matrix A.
  On exit,  A is overwritten by the balanced matrix.
  If JOB = 'N', A is not referenced.
  See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

ILO

IHI
  ILO and IHI are set to INTEGER such that on exit
  A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE
  SCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied to
  A.  If P(j) is the index of the row and column interchanged
  with row and column j and D(j) is the scaling factor
  applied to row and column j, then
  SCALE(j) = P(j)    for j = 1,...,ILO-1
           = D(j)    for j = ILO,...,IHI
           = P(j)    for j = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:
  The permutations consist of row and column interchanges which put
  the matrix in the form

                         ( T1   X   Y  )
               P A P = (  0   B   Z  )
                         (  0   0   T2 )
```

```
where T1 and T2 are upper triangular matrices whose eigenvalues lie
along the diagonal.  The column indices ILO and IHI mark the starting
and ending columns of the submatrix B. Balancing consists of applying
a diagonal similarity transformation inv(D) * B * D to make the
1-norms of each row of B and its corresponding column nearly equal.
The output matrix is

             ( T1     X*D          Y    )
             (  0  inv(D)*B*D  inv(D)*Z ).
             (  0      0           T2   )

Information about the permutations P and the diagonal matrix D is
returned in the vector SCALE.

This subroutine is based on the EISPACK routine CBAL.

SYNOPSIS
   Functions/Subroutines
       subroutine zgebd2 (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO)
           ZGEBD2 reduces a general matrix to bidiagonal form using an
           unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgebd2 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) D, double precision,
       dimension( * ) E, complex*16, dimension( * ) TAUQ, complex*16,
       dimension( * ) TAUP, complex*16, dimension( * ) WORK, integer INFO)
       ZGEBD2 reduces a general matrix to bidiagonal form using an unblocked
       algorithm.

Purpose:
   ZGEBD2 reduces a complex general m by n matrix A to upper or lower
   real bidiagonal form B by a unitary transformation: Q**H * A * P = B.

   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the m by n general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
      overwritten with the upper bidiagonal matrix B; the
      elements below the diagonal, with the array TAUQ, represent
```

```
      the unitary matrix Q as a product of elementary
      reflectors, and the elements above the first superdiagonal,
      with the array TAUP, represent the unitary matrix P as
      a product of elementary reflectors;
   if m < n, the diagonal and the first subdiagonal are
      overwritten with the lower bidiagonal matrix B; the
      elements below the first subdiagonal, with the array TAUQ,
      represent the unitary matrix Q as a product of
      elementary reflectors, and the elements above the diagonal,
      with the array TAUP, represent the unitary matrix P as
      a product of elementary reflectors.
   See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 D
   D is DOUBLE PRECISION array, dimension (min(M,N))
   The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

 E
   E is DOUBLE PRECISION array, dimension (min(M,N)-1)
   The off-diagonal elements of the bidiagonal matrix B:
   if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
   if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

 TAUQ
   TAUQ is COMPLEX*16 array dimension (min(M,N))
   The scalar factors of the elementary reflectors which
   represent the unitary matrix Q. See Further Details.

 TAUP
   TAUP is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors which
   represent the unitary matrix P. See Further Details.

 WORK
   WORK is COMPLEX*16 array, dimension (max(M,N))

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrices Q and P are represented as products of elementary
   reflectors:
```

```
If m >= n,

Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

Each H(i) and G(i) has the form:

H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

where tauq and taup are complex scalars, and v and u are complex
vectors; v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in
A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in
A(i,i+2:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

If m < n,

Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

where tauq and taup are complex scalars, v and u are complex vectors;
v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n);
tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

          m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

            (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
            (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
            (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
            (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
            (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
            (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal elements of B, vi
denotes an element of the vector defining H(i), and ui an element of
the vector defining G(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgebrd (M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)
           ZGEBRD

Function/Subroutine Documentation
   subroutine zgebrd (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) D, double precision,
       dimension( * ) E, complex*16, dimension( * ) TAUQ, complex*16,
       dimension( * ) TAUP, complex*16, dimension( * ) WORK, integer LWORK,
       integer INFO)
       ZGEBRD

Purpose:

   ZGEBRD reduces a general complex M-by-N matrix A to upper or lower
   bidiagonal form B by a unitary transformation: Q**H * A * P = B.

   If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

Parameters:

 M
   M is INTEGER
   The number of rows in the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns in the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N general matrix to be reduced.
   On exit,
   if m >= n, the diagonal and the first superdiagonal are
      overwritten with the upper bidiagonal matrix B; the
      elements below the diagonal, with the array TAUQ, represent
      the unitary matrix Q as a product of elementary
      reflectors, and the elements above the first superdiagonal,
      with the array TAUP, represent the unitary matrix P as
      a product of elementary reflectors;
   if m < n, the diagonal and the first subdiagonal are
```

```
      overwritten with the lower bidiagonal matrix B; the
      elements below the first subdiagonal, with the array TAUQ,
      represent the unitary matrix Q as a product of
      elementary reflectors, and the elements above the diagonal,
      with the array TAUP, represent the unitary matrix P as
      a product of elementary reflectors.
  See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

D
  D is DOUBLE PRECISION array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E
  E is DOUBLE PRECISION array, dimension (min(M,N)-1)
  The off-diagonal elements of the bidiagonal matrix B:
  if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1;
  if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ
  TAUQ is COMPLEX*16 array dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the unitary matrix Q. See Further Details.

TAUP
  TAUP is COMPLEX*16 array, dimension (min(M,N))
  The scalar factors of the elementary reflectors which
  represent the unitary matrix P. See Further Details.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,M,N).
  For optimum performance LWORK >= (M+N)*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit.
```

```
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrices Q and P are represented as products of elementary
   reflectors:

   If m >= n,

   Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

   Each H(i) and G(i) has the form:

   H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

   where tauq and taup are complex scalars, and v and u are complex
   vectors; v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in
   A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in
   A(i,i+2:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

   If m < n,

   Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

   Each H(i) and G(i) has the form:

   H(i) = I - tauq * v * v**H  and G(i) = I - taup * u * u**H

   where tauq and taup are complex scalars, and v and u are complex
   vectors; v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in
   A(i+2:m,i); u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in
   A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

   The contents of A on exit are illustrated by the following examples:

             m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

               (  d   e   u1  u1  u1 )           (  d   u1  u1  u1  u1  u1 )
               (  v1  d   e   u2  u2 )           (  e   d   u2  u2  u2  u2 )
               (  v1  v2  d   e   u3 )           (  v1  e   d   u3  u3  u3 )
               (  v1  v2  v3  d   e  )           (  v1  v2  e   d   u4  u4 )
               (  v1  v2  v3  v4  d  )           (  v1  v2  v3  e   d   u5 )
               (  v1  v2  v3  v4  v5 )

   where d and e denote diagonal and off-diagonal elements of B, vi
   denotes an element of the vector defining H(i), and ui an element of
   the vector defining G(i).

          ______-

SYNOPSIS
   Functions/Subroutines
       subroutine zgecon (NORM, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
           ZGECON

Function/Subroutine Documentation
   subroutine zgecon (character NORM, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, double precision ANORM, double precision RCOND,
       complex*16, dimension( * ) WORK, double precision, dimension( * )
       RWORK, integer INFO)
       ZGECON

Purpose:
   ZGECON estimates the reciprocal of the condition number of a general
   complex matrix A, in either the 1-norm or the infinity-norm, using
   the LU factorization computed by ZGETRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
      RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.
```

```
N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The factors L and U from the factorization A = P*L*U
  as computed by ZGETRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

ANORM
  ANORM is DOUBLE PRECISION
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgeequ (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, INFO)
           ZGEEQU

Function/Subroutine Documentation
   subroutine zgeequ (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) R, double precision,
       dimension( * ) C, double precision ROWCND, double precision COLCND,
       double precision AMAX, integer INFO)
       ZGEEQU

Purpose:
   ZGEEQU computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

   R(i) and C(j) are restricted to be between SMLNUM = smallest safe
   number and BIGNUM = largest safe number.  Use of these scaling
   factors is not guaranteed to reduce the condition number of A but
   works well in practice.

Parameters:
```

```
M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The M-by-N matrix whose equilibration factors are to be computed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

R
  R is DOUBLE PRECISION array, dimension (M)
  If INFO = 0 or INFO > M, R contains the row scale factors for A.

C
  C is DOUBLE PRECISION array, dimension (N)
  If INFO = 0,  C contains the column scale factors for A.

ROWCND
  ROWCND is DOUBLE PRECISION
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is DOUBLE PRECISION
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i,  and i is
    <= M:  the i-th row of A is exactly zero
    >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgehd2 (N, ILO, IHI, A, LDA, TAU, WORK, INFO)
           ZGEHD2 reduces a general square matrix to upper Hessenberg form
           using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgehd2 (integer N, integer ILO, integer IHI, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( * ) TAU,
       complex*16, dimension( * ) WORK, integer INFO)
       ZGEHD2 reduces a general square matrix to upper Hessenberg form using
       an unblocked algorithm.

Purpose:
   ZGEHD2 reduces a complex general matrix A to upper Hessenberg form H
   by a unitary similarity transformation:  Q**H * A * Q = H .

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to ZGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= max(1,N).

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the n by n general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the unitary matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
```

```
   TAU is COMPLEX*16 array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrix Q is represented as a product of (ihi-ilo) elementary
   reflectors

   Q = H(ilo) H(ilo+1) . . . H(ihi-1).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
   exit in A(i+2:ihi,i), and tau in TAU(i).

   The contents of A are illustrated by the following example, with
   n = 7, ilo = 2 and ihi = 6:

             on entry,                        on exit,

             ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
             (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
             (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
             (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
             (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
             (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
             (                         a )    (                          a )

   where a denotes an element of the original matrix A, h denotes a
   modified element of the upper Hessenberg matrix H, and vi denotes an
   element of the vector defining H(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgehd2 (N, ILO, IHI, A, LDA, TAU, WORK, INFO)
           ZGEHD2 reduces a general square matrix to upper Hessenberg form
           using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgehd2 (integer N, integer ILO, integer IHI, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( * ) TAU,
       complex*16, dimension( * ) WORK, integer INFO)
       ZGEHD2 reduces a general square matrix to upper Hessenberg form using
       an unblocked algorithm.

Purpose:
   ZGEHD2 reduces a complex general matrix A to upper Hessenberg form H
   by a unitary similarity transformation:  Q**H * A * Q = H .
```

```
Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to ZGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= max(1,N).

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the n by n general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the unitary matrix Q as a product of elementary
   reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is COMPLEX*16 array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrix Q is represented as a product of (ihi-ilo) elementary
   reflectors

   Q = H(ilo) H(ilo+1) . . . H(ihi-1).
```

```
Each H(i) has the form

H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with
n = 7, ilo = 2 and ihi = 6:

          on entry,                        on exit,

          ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
          (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
          (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
          (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
          (                         a )    (                          a )

where a denotes an element of the original matrix A, h denotes a
modified element of the upper Hessenberg matrix H, and vi denotes an
element of the vector defining H(i).

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zgehrd (N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
           ZGEHRD

Function/Subroutine Documentation
   subroutine zgehrd (integer N, integer ILO, integer IHI, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( * ) TAU,
       complex*16, dimension( * ) WORK, integer LWORK, integer INFO)
       ZGEHRD

Purpose:
   ZGEHRD reduces a complex general matrix A to upper Hessenberg form H by
   an unitary similarity transformation:  Q**H * A * Q = H .

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER

   It is assumed that A is already upper triangular in rows
   and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
   set by a previous call to ZGEBAL; otherwise they should be
   set to 1 and N respectively. See Further Details.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N general matrix to be reduced.
   On exit, the upper triangle and the first subdiagonal of A
   are overwritten with the upper Hessenberg matrix H, and the
   elements below the first subdiagonal, with the array TAU,
   represent the unitary matrix Q as a product of elementary
   reflectors. See Further Details.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 TAU
   TAU is COMPLEX*16 array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further
   Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

 WORK
   WORK is COMPLEX*16 array, dimension (LWORK)
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of the array WORK.  LWORK >= max(1,N).
   For good performance, LWORK should generally be larger.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrix Q is represented as a product of (ihi-ilo) elementary
   reflectors

   Q = H(ilo) H(ilo+1) . . . H(ihi-1).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on
   exit in A(i+2:ihi,i), and tau in TAU(i).

   The contents of A are illustrated by the following example, with
   n = 7, ilo = 2 and ihi = 6:

             on entry,                        on exit,

             ( a   a   a   a   a   a   a )    ( a   a   h   h   h   h   a )
             (     a   a   a   a   a   a )    (     a   h   h   h   h   a )
```

```
(     a   a   a   a   a   a )    (      h   h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
(                         a )    (                          a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgelq2 (M, N, A, LDA, TAU, WORK, INFO)
           ZGELQ2 computes the LQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgelq2 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
       WORK, integer INFO)
       ZGELQ2 computes the LQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   ZGELQ2 computes an LQ factorization of a complex m by n matrix A:
   A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and below the diagonal of the array
   contain the m by min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the unitary matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
```

```
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(k)**H . . . H(2)**H H(1)**H, where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(1:i-1) = 0 and v(i) = 1; conjg(v(i+1:n)) is stored on exit in
   A(i,i+1:n), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgelqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           ZGELQF

Function/Subroutine Documentation
   subroutine zgelqf (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
       WORK, integer LWORK, integer INFO)
       ZGELQF

Purpose:
   ZGELQF computes an LQ factorization of a complex M-by-N matrix A:
   A = L * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and below the diagonal of the array
   contain the m-by-min(m,n) lower trapezoidal matrix L (L is
   lower triangular if m <= n); the elements above the diagonal,
   with the array TAU, represent the unitary matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).
```

```
 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,M).
   For optimum performance LWORK >= M*NB, where NB is the
   optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(k)**H . . . H(2)**H H(1)**H, where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(1:i-1) = 0 and v(i) = 1; conjg(v(i+1:n)) is stored on exit in
   A(i,i+1:n), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgemqrt (SIDE, TRANS, M, N, K, NB, V, LDV, T, LDT, C, LDC,
           WORK, INFO)
           ZGEMQRT

Function/Subroutine Documentation
   subroutine zgemqrt (character SIDE, character TRANS, integer M, integer N,
       integer K, integer NB, complex*16, dimension( ldv, * ) V, integer LDV,
       complex*16, dimension( ldt, * ) T, integer LDT, complex*16, dimension(
       ldc, * ) C, integer LDC, complex*16, dimension( * ) WORK, integer INFO)
       ZGEMQRT

Purpose:
   ZGEMQRT overwrites the general complex M-by-N matrix C with

                             SIDE = 'L'     SIDE = 'R'
             TRANS = 'N':      Q C            C Q
             TRANS = 'C':    Q**H C            C Q**H

   where Q is a complex orthogonal matrix defined as the product of K
   elementary reflectors:

   Q = H(1) H(2) . . . H(K) = I - V T V**H

   generated using the compact WY representation as returned by ZGEQRT.

   Q is of order M if SIDE = 'L' and of order N  if SIDE = 'R'.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'L': apply Q or Q**H from the Left;
   = 'R': apply Q or Q**H from the Right.

 TRANS
   TRANS is CHARACTER*1
   = 'N':  No transpose, apply Q;
   = 'C':  Transpose, apply Q**H.
```

```
M
  M is INTEGER
  The number of rows of the matrix C. M >= 0.

N
  N is INTEGER
  The number of columns of the matrix C. N >= 0.

K
  K is INTEGER
  The number of elementary reflectors whose product defines
  the matrix Q.
  If SIDE = 'L', M >= K >= 0;
  if SIDE = 'R', N >= K >= 0.

NB
  NB is INTEGER
  The block size used for the storage of T.  K >= NB >= 1.
  This must be the same value of NB used to generate T in CGEQRT.

V
  V is COMPLEX*16 array, dimension (LDV,K)
  The i-th column must contain the vector which defines the
  elementary reflector H(i), for i = 1,2,...,k, as returned by
  CGEQRT in the first K columns of its array argument A.

LDV
  LDV is INTEGER
  The leading dimension of the array V.
  If SIDE = 'L', LDA >= max(1,M);
  if SIDE = 'R', LDA >= max(1,N).

T
  T is COMPLEX*16 array, dimension (LDT,K)
  The upper triangular factors of the block reflectors
  as returned by CGEQRT, stored as a NB-by-N matrix.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= NB.

C
  C is COMPLEX*16 array, dimension (LDC,N)
  On entry, the M-by-N matrix C.
  On exit, C is overwritten by Q C, Q**H C, C Q**H or C Q.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M).
```

```
 WORK
   WORK is COMPLEX*16 array. The dimension of WORK is
   N*NB if SIDE = 'L', or  M*NB if SIDE = 'R'.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zgeql2 (M, N, A, LDA, TAU, WORK, INFO)
           ZGEQL2 computes the QL factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgeql2 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
       WORK, integer INFO)
       ZGEQL2 computes the QL factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   ZGEQL2 computes a QL factorization of a complex m by n matrix A:
   A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
```

```
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the m by n matrix A.
  On exit, if m >= n, the lower triangle of the subarray
  A(m-n+1:m,1:n) contains the n by n lower triangular matrix L;
  if m <= n, the elements on and below the (n-m)-th
  superdiagonal contain the m by n lower trapezoidal matrix L;
  the remaining elements, with the array TAU, represent the
  unitary matrix Q as a product of elementary reflectors
  (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX*16 array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX*16 array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

  The matrix Q is represented as a product of elementary reflectors

  Q = H(k) . . . H(2) H(1), where k = min(m,n).

  Each H(i) has the form

  H(i) = I - tau * v * v**H

  where tau is a complex scalar, and v is a complex vector with
  v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
  A(1:m-k+i-1,n-k+i), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqlf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           ZGEQLF

Function/Subroutine Documentation
   subroutine zgeqlf (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
       WORK, integer LWORK, integer INFO)
       ZGEQLF

Purpose:
   ZGEQLF computes a QL factorization of a complex M-by-N matrix A:
   A = Q * L.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m >= n, the lower triangle of the subarray
   A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L;
```

```
   if m <= n, the elements on and below the (n-m)-th
   superdiagonal contain the M-by-N lower trapezoidal matrix L;
   the remaining elements, with the array TAU, represent the
   unitary matrix Q as a product of elementary reflectors
   (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimum performance LWORK >= N*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(k) . . . H(2) H(1), where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in
   A(1:m-k+i-1,n-k+i), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqp3 (M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK, INFO)
           ZGEQP3

Function/Subroutine Documentation
   subroutine zgeqp3 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) JPVT, complex*16, dimension( * )
       TAU, complex*16, dimension( * ) WORK, integer LWORK, double precision,
       dimension( * ) RWORK, integer INFO)
       ZGEQP3

Purpose:
   ZGEQP3 computes a QR factorization with column pivoting of a
   matrix A:  A*P = Q*R  using Level 3 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A. M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the upper triangle of the array contains the
   min(M,N)-by-N upper trapezoidal matrix R; the elements below
   the diagonal, together with the array TAU, represent the
   unitary matrix Q as a product of min(M,N) elementary reflectors.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,M).

 JPVT
   JPVT is INTEGER array, dimension (N)
   On entry, if JPVT(J).ne.0, the J-th column of A is permuted
   to the front of A*P (a leading column); if JPVT(J)=0,
   the J-th column of A is a free column.
   On exit, if JPVT(J)=K, then the J-th column of A*P was the
   the K-th column of A.
```

```
 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors.

 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO=0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK >= N+1.
   For optimal performance LWORK >= ( N+1 )*NB, where NB
   is the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0: successful exit.
   < 0: if INFO = -i, the i-th argument had an illegal value.

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a real/complex vector
   with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in
   A(i+1:m,i), and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqr2 (M, N, A, LDA, TAU, WORK, INFO)
           ZGEQR2 computes the QR factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgeqr2 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
       WORK, integer INFO)
       ZGEQR2 computes the QR factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   ZGEQR2 computes a QR factorization of a complex m by n matrix A:
   A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n); the elements below the diagonal,
   with the array TAU, represent the unitary matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
```

```
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
   and tau in TAU(i).

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqr2p (M, N, A, LDA, TAU, WORK, INFO)
           ZGEQR2P computes the QR factorization of a general rectangular
           matrix with non-negative diagonal elements using an unblocked
           algorithm.

Function/Subroutine Documentation
   subroutine zgeqr2p (integer M, integer N, complex*16, dimension( lda, * )
       A, integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension(
       * ) WORK, integer INFO)
       ZGEQR2P computes the QR factorization of a general rectangular matrix
```

```
       with non-negative diagonal elements using an unblocked algorithm.

Purpose:
   ZGEQR2P computes a QR factorization of a complex m by n matrix A:
   A = Q * R. The diagonal entries of R are real and nonnegative.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(m,n) by n upper trapezoidal matrix R (R is
   upper triangular if m >= n). The diagonal entries of R
   are real and nonnegative; the elements below the diagonal,
   with the array TAU, represent the unitary matrix Q as a
   product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

   Each H(i) has the form
```

```
H(i) = I - tau * v * v**H

where tau is a complex scalar, and v is a complex vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
and tau in TAU(i).

       ZGEQRF

Purpose:
   ZGEQRF computes a QR factorization of a complex M-by-N matrix A:
   A = Q * R.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
```

```
  upper triangular if m >= n); the elements below the diagonal,
  with the array TAU, represent the unitary matrix Q as a
  product of min(m,n) elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX*16 array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimum performance LWORK >= N*NB, where NB is
  the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

  The matrix Q is represented as a product of elementary reflectors

  Q = H(1) H(2) . . . H(k), where k = min(m,n).

  Each H(i) has the form

  H(i) = I - tau * v * v**H

  where tau is a complex scalar, and v is a complex vector with
  v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
  and tau in TAU(i).

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqrfp (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           ZGEQRFP

Function/Subroutine Documentation
   subroutine zgeqrfp (integer M, integer N, complex*16, dimension( lda, * )
       A, integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension(
       * ) WORK, integer LWORK, integer INFO)
       ZGEQRFP

Purpose:
   ZGEQRFP computes a QR factorization of a complex M-by-N matrix A:
   A = Q * R. The diagonal entries of R are real and nonnegative.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
```

```
  On exit, the elements on and above the diagonal of the array
  contain the min(M,N)-by-N upper trapezoidal matrix R (R is
  upper triangular if m >= n). The diagonal entries of R
  are real and nonnegative; The elements below the diagonal,
  with the array TAU, represent the unitary matrix Q as a
  product of min(m,n) elementary reflectors (see Further Details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

TAU
  TAU is COMPLEX*16 array, dimension (min(M,N))
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).
  For optimum performance LWORK >= N*NB, where NB is
  the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

  The matrix Q is represented as a product of elementary reflectors

  Q = H(1) H(2) . . . H(k), where k = min(m,n).

  Each H(i) has the form

  H(i) = I - tau * v * v**H

  where tau is a complex scalar, and v is a complex vector with
  v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
  and tau in TAU(i).

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqrt (M, N, NB, A, LDA, T, LDT, WORK, INFO)
           ZGEQRT

Function/Subroutine Documentation
   subroutine zgeqrt (integer M, integer N, integer NB, complex*16, dimension(
       lda, * ) A, integer LDA, complex*16, dimension( ldt, * ) T, integer
       LDT, complex*16, dimension( * ) WORK, integer INFO)
       ZGEQRT

Purpose:
   ZGEQRT computes a blocked QR factorization of a complex M-by-N matrix A
   using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
 NB
   NB is INTEGER
   The block size to be used in the blocked QR.  MIN(M,N) >= NB >= 1.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit, the elements on and above the diagonal of the array
   contain the min(M,N)-by-N upper trapezoidal matrix R (R is
   upper triangular if M >= N); the elements below the diagonal
   are the columns of V.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is COMPLEX*16 array, dimension (LDT,MIN(M,N))
   The upper triangular block reflectors stored in compact form
   as a sequence of upper triangular blocks.  See below
   for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= NB.

 WORK
   WORK is COMPLEX*16 array, dimension (NB*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                         V = (  1       )
                             ( v1  1    )
                             ( v1 v2  1 )
                             ( v1 v2 v3 )
                             ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.

   Let K=MIN(M,N).  The number of blocks is B = ceiling(K/NB), where each
   block is of order NB except for the last block, which is of order
```

```
IB = K - (B-1)*NB.  For each of the B blocks, a upper triangular block
reflector factor is computed: T1, T2, ..., TB.  The NB-by-NB (and IB-by-IB
for the last block) T's are stored in the NB-by-N matrix T as

                       T = (T1 T2 ... TB).
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zgeqrt2 (M, N, A, LDA, T, LDT, INFO)
           ZGEQRT2 computes a QR factorization of a general real or complex
           matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   subroutine zgeqrt2 (integer M, integer N, complex*16, dimension( lda, * )
       A, integer LDA, complex*16, dimension( ldt, * ) T, integer LDT, integer
       INFO)
       ZGEQRT2 computes a QR factorization of a general real or complex matrix
       using the compact WY representation of Q.

Purpose:
   ZGEQRT2 computes a QR factorization of a complex M-by-N matrix A,
   using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the complex M-by-N matrix A.  On exit, the elements on and
   above the diagonal contain the N-by-N upper triangular matrix R; the
   elements below the diagonal are the columns of V.  See below for
   further details.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is COMPLEX*16 array, dimension (LDT,N)
   The N-by-N upper triangular factor of the block reflector.
   The elements on and above the diagonal contain the block
   reflector T; the elements below the diagonal are not used.
   See below for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                         V = (  1       )
                             ( v1  1    )
                             ( v1 v2  1 )
                             ( v1 v2 v3 )
                             ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
   block reflector H is then given by

                         H = I - V * T * V**H

   where V**H is the conjugate transpose of V.

====================================================================

SYNOPSIS
   Functions/Subroutines
       recursive subroutine zgeqrt3 (M, N, A, LDA, T, LDT, INFO)
           ZGEQRT3 recursively computes a QR factorization of a general real
           or complex matrix using the compact WY representation of Q.

Function/Subroutine Documentation
   recursive subroutine zgeqrt3 (integer M, integer N, complex*16, dimension(
       lda, * ) A, integer LDA, complex*16, dimension( ldt, * ) T, integer
       LDT, integer INFO)
       ZGEQRT3 recursively computes a QR factorization of a general real or
       complex matrix using the compact WY representation of Q.

Purpose:
   ZGEQRT3 recursively computes a QR factorization of a complex M-by-N
   matrix A, using the compact WY representation of Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= N.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the complex M-by-N matrix A.  On exit, the elements on
   and above the diagonal contain the N-by-N upper triangular matrix R;
   the elements below the diagonal are the columns of V.  See below for
   further details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 T
   T is COMPLEX*16 array, dimension (LDT,N)
   The N-by-N upper triangular factor of the block reflector.
   The elements on and above the diagonal contain the block
   reflector T; the elements below the diagonal are not used.
```

```
   See below for further details.

 LDT
   LDT is INTEGER
   The leading dimension of the array T.  LDT >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix V stores the elementary reflectors H(i) in the i-th column
   below the diagonal. For example, if M=5 and N=3, the matrix V is

                         V = (  1       )
                             ( v1  1    )
                             ( v1 v2  1 )
                             ( v1 v2 v3 )
                             ( v1 v2 v3 )

   where the vi's represent the vectors which define H(i), which are returned
   in the matrix A.  The 1's along the diagonal of V are not stored in A.  The
   block reflector H is then given by

                         H = I - V * T * V**H

   where V**H is the conjugate transpose of V.

SYNOPSIS
   Functions/Subroutines
       subroutine zgerfs (TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, RWORK, INFO)
           ZGERFS

Function/Subroutine Documentation
   subroutine zgerfs (character TRANS, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldaf, * )
       AF, integer LDAF, integer, dimension( * ) IPIV, complex*16, dimension(
       ldb, * ) B, integer LDB, complex*16, dimension( ldx, * ) X, integer
       LDX, double precision, dimension( * ) FERR, double precision,
       dimension( * ) BERR, complex*16, dimension( * ) WORK, double precision,
       dimension( * ) RWORK, integer INFO)
       ZGERFS

Purpose:
   ZGERFS improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates for
   the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
```

```
  = 'C':  A**H * X = B  (Conjugate transpose)

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The original N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by ZGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from ZGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).
```

```
 FERR
   FERR is DOUBLE PRECISION array, dimension (NRHS)
   The estimated forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

       ZGERFSX

Purpose:
   ZGERFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
```

```
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  The right hand side B has been changed accordingly.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The original N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The factors L and U from the factorization A = P*L*U
  as computed by ZGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from ZGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.
  If R is accessed, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be
  reliable.
```

```
C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.
  If C is accessed, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.
```

```
ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
          max_j (abs(XTRUE(j,i) - X(j,i)))
           ------------------------------
                 max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))
```

```
  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
```

```
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be
              trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
         not guaranteed. The solutions corresponding to other right-
         hand sides K with K > J may not be guaranteed as well, but
         only the first such right-hand side is reported. If a small
         componentwise error is not requested (PARAMS(3) = 0.0) then
         the Jth right-hand side is the first with a normwise error
         bound that is not guaranteed (the smallest J such
         that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
         the Jth right-hand side is the first with either a normwise or
         componentwise error bound that is not guaranteed (the smallest
         J such that either ERR_BNDS_NORM(J,1) = 0.0 or
         ERR_BNDS_COMP(J,1) = 0.0). See the definition of
         ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
         about all of the right-hand sides check ERR_BNDS_NORM or

SYNOPSIS
   Functions/Subroutines
       subroutine zgerq2 (M, N, A, LDA, TAU, WORK, INFO)
           ZGERQ2 computes the RQ factorization of a general rectangular
           matrix using an unblocked algorithm.

Function/Subroutine Documentation
   subroutine zgerq2 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
       WORK, integer INFO)
       ZGERQ2 computes the RQ factorization of a general rectangular matrix
       using an unblocked algorithm.

Purpose:
   ZGERQ2 computes an RQ factorization of a complex m by n matrix A:
   A = R * Q.
```

```
 Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the m by n matrix A.
   On exit, if m <= n, the upper triangle of the subarray
   A(1:m,n-m+1:n) contains the m by m upper triangular matrix R;
   if m >= n, the elements on and above the (m-n)-th subdiagonal
   contain the m by n upper trapezoidal matrix R; the remaining
   elements, with the array TAU, represent the unitary matrix
   Q as a product of elementary reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (M)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(1)**H H(2)**H . . . H(k)**H, where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(n-k+i+1:n) = 0 and v(n-k+i) = 1; conjg(v(1:n-k+i-1)) is stored on
   exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgerqf (M, N, A, LDA, TAU, WORK, LWORK, INFO)
           ZGERQF

Function/Subroutine Documentation
   subroutine zgerqf (integer M, integer N, complex*16, dimension( lda, * ) A,
```

```
      integer LDA, complex*16, dimension( * ) TAU, complex*16, dimension( * )
      WORK, integer LWORK, integer INFO)
      ZGERQF

Purpose:
   ZGERQF computes an RQ factorization of a complex M-by-N matrix A:
   A = R * Q.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix A.
   On exit,
   if m <= n, the upper triangle of the subarray
   A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R;
   if m >= n, the elements on and above the (m-n)-th subdiagonal
   contain the M-by-N upper trapezoidal matrix R;
   the remaining elements, with the array TAU, represent the
   unitary matrix Q as a product of min(m,n) elementary
   reflectors (see Further Details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 TAU
   TAU is COMPLEX*16 array, dimension (min(M,N))
   The scalar factors of the elementary reflectors (see Further Details).

 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,M).
   For optimum performance LWORK >= M*NB, where NB is
   the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
```

```
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

   The matrix Q is represented as a product of elementary reflectors

   Q = H(1)**H H(2)**H . . . H(k)**H, where k = min(m,n).

   Each H(i) has the form

   H(i) = I - tau * v * v**H

   where tau is a complex scalar, and v is a complex vector with
   v(n-k+i+1:n) = 0 and v(n-k+i) = 1; conjg(v(1:n-k+i-1)) is stored on
   exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).
```

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zgetf2 (M, N, A, LDA, IPIV, INFO)
           ZGETF2 computes the LU factorization of a general m-by-n matrix
           using partial pivoting with row interchanges (unblocked algorithm).

Function/Subroutine Documentation
   subroutine zgetf2 (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       ZGETF2 computes the LU factorization of a general m-by-n matrix using
       partial pivoting with row interchanges (unblocked algorithm).

Purpose:
   ZGETF2 computes an LU factorization of a general m-by-n matrix A
   using partial pivoting with row interchanges.

   The factorization has the form A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 2 BLAS version of the algorithm.

Parameters:

 M
   M is INTEGER
```

```
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the m by n matrix to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U; the unit diagonal elements of L are not stored.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
  > 0: if INFO = k, U(k,k) is exactly zero. The factorization
       has been completed, but the factor U is exactly
       singular, and division by zero will occur if it is used
       to solve a system of equations.

SYNOPSIS
   Functions/Subroutines
       subroutine zgetrf (M, N, A, LDA, IPIV, INFO)
           ZGETRF

Function/Subroutine Documentation
   subroutine zgetrf (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       ZGETRF

Purpose:
   ZGETRF computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
   A = P * L * U
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the right-looking Level 3 BLAS version of the algorithm.

Parameters:

 M
```

```
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the M-by-N matrix to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U; the unit diagonal elements of L are not stored.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
        has been completed, but the factor U is exactly
        singular, and division by zero will occur if it is used
        to solve a system of equations.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       recursive subroutine zgetrf2 (M, N, A, LDA, IPIV, INFO)
           ZGETRF2

Function/Subroutine Documentation
   recursive subroutine zgetrf2 (integer M, integer N, complex*16, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       ZGETRF2

Purpose:
   ZGETRF2 computes an LU factorization of a general M-by-N matrix A
   using partial pivoting with row interchanges.

   The factorization has the form
   A = P * L * U
```

```
   where P is a permutation matrix, L is lower triangular with unit
   diagonal elements (lower trapezoidal if m > n), and U is upper
   triangular (upper trapezoidal if m < n).

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

               [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
           A = [ -----|----- ]  with n1 = min(m,n)
               [  A21 | A22  ]       n2 = n-n1

                                                [ A11 ]
   The subroutine calls itself to factor [ --- ],
                                                [ A12 ]
                    [ A12 ]
   do the swaps on  [ --- ], solve A12, update A22,
                    [ A22 ]

   then calls itself to factor A22 and do the swaps on A21.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M-by-N matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U; the unit diagonal elements of L are not stored.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero. The factorization
```

```
has been completed, but the factor U is exactly
singular, and division by zero will occur if it is used
to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgetri (N, A, LDA, IPIV, WORK, LWORK, INFO)
           ZGETRI

Function/Subroutine Documentation
   subroutine zgetri (integer N, complex*16, dimension( lda, * ) A, integer
       LDA, integer, dimension( * ) IPIV, complex*16, dimension( * ) WORK,
       integer LWORK, integer INFO)
       ZGETRI

Purpose:
```

```
  ZGETRI computes the inverse of a matrix using the LU factorization
  computed by ZGETRF.

  This method inverts U and then computes inv(A) by solving the system
  inv(A)*L = inv(U) for inv(A).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the factors L and U from the factorization
   A = P*L*U as computed by ZGETRF.
   On exit, if INFO = 0, the inverse of the original matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from ZGETRF; for 1<=i<=N, row i of the
   matrix was interchanged with row IPIV(i).

 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO=0, then WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.  LWORK >= max(1,N).
   For optimal performance LWORK >= N*NB, where NB is
   the optimal blocksize returned by ILAENV.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero; the matrix is
         singular and its inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgetrs (TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           ZGETRS

Function/Subroutine Documentation
   subroutine zgetrs (character TRANS, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB, integer INFO)
       ZGETRS

Purpose:
   ZGETRS solves a system of linear equations
      A * X = B,  A**T * X = B,  or  A**H * X = B
   with a general N-by-N matrix A using the LU factorization computed
   by ZGETRF.
```

```
Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The factors L and U from the factorization A = P*L*U
   as computed by ZGETRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from ZGETRF; for 1<=i<=N, row i of the
   matrix was interchanged with row IPIV(i).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

       dimension( ldq, * ) Q, integer LDQ, complex*16, dimension( ldz, * ) Z,
       integer LDZ, complex*16, dimension( * ) WORK, integer LWORK, double
       precision, dimension( * ) RWORK, integer INFO)
       ZHGEQZ

Purpose:
   ZHGEQZ computes the eigenvalues of a complex matrix pair (H,T),
   where H is an upper Hessenberg matrix and T is upper triangular,
   using the single-shift QZ method.
   Matrix pairs of this type are produced by the reduction to
   generalized upper Hessenberg form of a complex matrix pair (A,B):

   A = Q1*H*Z1**H,  B = Q1*T*Z1**H,

   as computed by ZGGHRD.

   If JOB='S', then the Hessenberg-triangular pair (H,T) is
   also reduced to generalized Schur form,

   H = Q*S*Z**H,  T = Q*P*Z**H,

   where Q and Z are unitary matrices and S and P are upper triangular.

   Optionally, the unitary matrix Q from the generalized Schur
   factorization may be postmultiplied into an input matrix Q1, and the
   unitary matrix Z may be postmultiplied into an input matrix Z1.
   If Q1 and Z1 are the unitary matrices from ZGGHRD that reduced
   the matrix pair (A,B) to generalized Hessenberg form, then the output
   matrices Q1*Q and Z1*Z are the unitary factors from the generalized
   Schur factorization of (A,B):

   A = (Q1*Q)*S*(Z1*Z)**H,  B = (Q1*Q)*P*(Z1*Z)**H.

   To avoid overflow, eigenvalues of the matrix pair (H,T)
   (equivalently, of (A,B)) are computed as a pair of complex values
   (alpha,beta).  If beta is nonzero, lambda = alpha / beta is an
   eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)
       A*x = lambda*B*x
   and if alpha is nonzero, mu = beta / alpha is an eigenvalue of the
   alternate form of the GNEP
       mu*A*y = B*y.
   The values of alpha and beta for the i-th eigenvalue can be read
   directly from the generalized Schur form:  alpha = S(i,i),
```

```
   beta = P(i,i).

Parameters:

 JOB
   JOB is CHARACTER*1
   = 'E': Compute eigenvalues only;
   = 'S': Computer eigenvalues and the Schur form.

 COMPQ
   COMPQ is CHARACTER*1
   = 'N': Left Schur vectors (Q) are not computed;
   = 'I': Q is initialized to the unit matrix and the matrix Q
          of left Schur vectors of (H,T) is returned;
   = 'V': Q must contain a unitary matrix Q1 on entry and
          the product Q1*Q is returned.

 COMPZ
   COMPZ is CHARACTER*1
   = 'N': Right Schur vectors (Z) are not computed;
   = 'I': Q is initialized to the unit matrix and the matrix Z
          of right Schur vectors of (H,T) is returned;
   = 'V': Z must contain a unitary matrix Z1 on entry and
          the product Z1*Z is returned.

 N
   N is INTEGER
   The order of the matrices H, T, Q, and Z.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   ILO and IHI mark the rows and columns of H which are in
   Hessenberg form.  It is assumed that A is already upper
   triangular in rows and columns 1:ILO-1 and IHI+1:N.
   If N > 0, 1 <= ILO <= IHI <= N; if N = 0, ILO=1 and IHI=0.

 H
   H is COMPLEX*16 array, dimension (LDH, N)
   On entry, the N-by-N upper Hessenberg matrix H.
   On exit, if JOB = 'S', H contains the upper triangular
   matrix S from the generalized Schur factorization.
   If JOB = 'E', the diagonal of H matches that of S, but
   the rest of H is unspecified.

 LDH
   LDH is INTEGER
   The leading dimension of the array H.  LDH >= max( 1, N ).
```

```
T
  T is COMPLEX*16 array, dimension (LDT, N)
  On entry, the N-by-N upper triangular matrix T.
  On exit, if JOB = 'S', T contains the upper triangular
  matrix P from the generalized Schur factorization.
  If JOB = 'E', the diagonal of T matches that of P, but
  the rest of T is unspecified.

LDT
  LDT is INTEGER
  The leading dimension of the array T.  LDT >= max( 1, N ).

ALPHA
  ALPHA is COMPLEX*16 array, dimension (N)
  The complex scalars alpha that define the eigenvalues of
  GNEP.  ALPHA(i) = S(i,i) in the generalized Schur factorization.

BETA
  BETA is COMPLEX*16 array, dimension (N)
  The real non-negative scalars beta that define the
  eigenvalues of GNEP.  BETA(i) = P(i,i) in the generalized
  Schur factorization.

  Together, the quantities alpha = ALPHA(j) and beta = BETA(j)
  represent the j-th eigenvalue of the matrix pair (A,B), in
  one of the forms lambda = alpha/beta or mu = beta/alpha.
  Since either lambda or mu may overflow, they should not,
  in general, be computed.

Q
  Q is COMPLEX*16 array, dimension (LDQ, N)
  On entry, if COMPZ = 'V', the unitary matrix Q1 used in the
  reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the unitary matrix of left Schur
  vectors of (H,T), and if COMPZ = 'V', the unitary matrix of
  left Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.  LDQ >= 1.
  If COMPQ='V' or 'I', then LDQ >= N.

Z
  Z is COMPLEX*16 array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the unitary matrix Z1 used in the
  reduction of (A,B) to generalized Hessenberg form.
  On exit, if COMPZ = 'I', the unitary matrix of right Schur
  vectors of (H,T), and if COMPZ = 'V', the unitary matrix of
```

```
  right Schur vectors of (A,B).
  Not referenced if COMPZ = 'N'.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1.
  If COMPZ='V' or 'I', then LDZ >= N.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1,...,N: the QZ iteration did not converge.  (H,T) is not
       in Schur form, but ALPHA(i) and BETA(i),
  i=INFO+1,...,N should be correct.
       = N+1,...,2*N: the shift calculation failed.  (H,T) is not
       in Schur form, but ALPHA(i) and BETA(i),
  i=INFO-N+1,...,N should be correct.

  We assume that complex ABS works as long as its value is less than
  overflow.

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zla_geamv (TRANS, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
           INCY)
           ZLA_GEAMV computes a matrix-vector product using a general matrix
           to calculate error bounds.

Function/Subroutine Documentation
   subroutine zla_geamv (integer TRANS, integer M, integer N, double precision
       ALPHA, complex*16, dimension( lda, * ) A, integer LDA, complex*16,
```

```
      dimension( * ) X, integer INCX, double precision BETA, double
      precision, dimension( * ) Y, integer INCY)
      ZLA_GEAMV computes a matrix-vector product using a general matrix to
      calculate error bounds.

Purpose:
   ZLA_GEAMV  performs one of the matrix-vector operations

           y := alpha*abs(A)*abs(x) + beta*abs(y),
      or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
   Unchanged on exit.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.
   Unchanged on exit.

 ALPHA
   ALPHA is DOUBLE PRECISION
```

```
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is COMPLEX*16 array of DIMENSION ( LDA, n )
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, m ).
  Unchanged on exit.

X
  X is COMPLEX*16 array of DIMENSION at least
     ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
     ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is DOUBLE PRECISION
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is DOUBLE PRECISION array, dimension
     ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
     ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.

SYNOPSIS
   Functions/Subroutines
       double precision function zla_gercond_c (TRANS, N, A, LDA, AF, LDAF,
           IPIV, C, CAPPLY, INFO, WORK, RWORK)
           ZLA_GERCOND_C computes the infinity norm condition number of
```

```
          op(A)*inv(diag(c)) for general matrices.

Function/Subroutine Documentation
   double precision function zla_gercond_c (character TRANS, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, double
       precision, dimension( * ) C, logical CAPPLY, integer INFO, complex*16,
       dimension( * ) WORK, double precision, dimension( * ) RWORK)
       ZLA_GERCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for general matrices.

Purpose:
   ZLA_GERCOND_C computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by ZGETRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices from the factorization A = P*L*U
   as computed by ZGETRF; row i of the matrix was interchanged
```

```
  with row IPIV(i).

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * inv(diag(C)).

CAPPLY
  CAPPLY is LOGICAL
  If .TRUE. then access the vector C in the formula above.

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX*16 array, dimension (2*N).
  Workspace.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_gercond_x (TRANS, N, A, LDA, AF, LDAF,
           IPIV, X, INFO, WORK, RWORK)
           ZLA_GERCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for general matrices.

Function/Subroutine Documentation
   double precision function zla_gercond_x (character TRANS, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, complex*16,
       dimension( * ) X, integer INFO, complex*16, dimension( * ) WORK, double
       precision, dimension( * ) RWORK)
       ZLA_GERCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for general matrices.

Purpose:
   ZLA_GERCOND_X computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX*16 vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
```

```
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by ZGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by ZGETRF; row i of the matrix was interchanged
  with row IPIV(i).

X
  X is COMPLEX*16 array, dimension (N)
  The vector X in the formula op(A) * diag(X).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX*16 array, dimension (2*N).
  Workspace.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N).
  Workspace.
```

       ZLA_GERFSX_EXTENDED

Purpose:
   ZLA_GERFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by ZGERFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERRS_N
   and ERRS_C for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERRS_N and ERRS_C.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 TRANS_TYPE
   TRANS_TYPE is INTEGER
   Specifies the transposition operation on A.
```

```
  The value is defined by ILATRANS(T) where T is a CHARACTER and
  T    = 'N':  No transpose
       = 'T':  Transpose
       = 'C':  Conjugate transpose

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by ZGETRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by ZGETRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
```

```
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX*16 array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by ZGETRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERRS_N
  and ERRS_C).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERRS_N
  ERRS_N is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                    max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.
```

```
  The first index in ERRS_N(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_N(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERRS_C
  ERRS_C is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                   abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERRS_C is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERRS_C(i,:) corresponds to the ith
  right-hand side.

  The second index in ERRS_C(:,err) contains the following
  three fields:
```

```
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace.

DY
  DY is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX*16 array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
```

```
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERRS_N and ERRS_C may no longer be trustworthy.

RTHRESH
  RTHRESH is DOUBLE PRECISION
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is DOUBLE PRECISION
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to ZGETRS had an illegal value
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       double precision function zla_gerpvgrw (N, NCOLS, A, LDA, AF, LDAF)
           ZLA_GERPVGRW multiplies a square real matrix by a complex matrix.

Function/Subroutine Documentation
   double precision function zla_gerpvgrw (integer N, integer NCOLS,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF)
       ZLA_GERPVGRW multiplies a square real matrix by a complex matrix.

Purpose:
   ZLA_GERPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
   The factors L and U from the factorization
   A = P*L*U as computed by ZGETRF.
```

```
 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ztgevc (SIDE, HOWMNY, SELECT, N, S, LDS, P, LDP, VL, LDVL,
           VR, LDVR, MM, M, WORK, RWORK, INFO)
           ZTGEVC

Function/Subroutine Documentation
   subroutine ztgevc (character SIDE, character HOWMNY, logical, dimension( *
       ) SELECT, integer N, complex*16, dimension( lds, * ) S, integer LDS,
       complex*16, dimension( ldp, * ) P, integer LDP, complex*16, dimension(
       ldvl, * ) VL, integer LDVL, complex*16, dimension( ldvr, * ) VR,
       integer LDVR, integer MM, integer M, complex*16, dimension( * ) WORK,
       double precision, dimension( * ) RWORK, integer INFO)
       ZTGEVC

Purpose:
```

```
   ZTGEVC computes some or all of the right and/or left eigenvectors of
   a pair of complex matrices (S,P), where S and P are upper triangular.
   Matrix pairs of this type are produced by the generalized Schur
   factorization of a complex matrix pair (A,B):

   A = Q*S*Z**H,  B = Q*P*Z**H

   as computed by ZGGHRD + ZHGEQZ.

   The right eigenvector x and the left eigenvector y of (S,P)
   corresponding to an eigenvalue w are defined by:

   S*x = w*P*x,  (y**H)*S = w*(y**H)*P,

   where y**H denotes the conjugate tranpose of y.
   The eigenvalues are not input to this routine, but are computed
   directly from the diagonal elements of S and P.

   This routine returns the matrices X and/or Y of right and left
   eigenvectors of (S,P), or the products Z*X and/or Q*Y,
   where Z and Q are input matrices.
   If Q and Z are the unitary factors from the generalized Schur
   factorization of a matrix pair (A,B), then Z*X and Q*Y
   are the matrices of right and left eigenvectors of (A,B).

Parameters:

 SIDE
   SIDE is CHARACTER*1
   = 'R': compute right eigenvectors only;
   = 'L': compute left eigenvectors only;
   = 'B': compute both right and left eigenvectors.

 HOWMNY
   HOWMNY is CHARACTER*1
   = 'A': compute all right and/or left eigenvectors;
   = 'B': compute all right and/or left eigenvectors,
      backtransformed by the matrices in VR and/or VL;
   = 'S': compute selected right and/or left eigenvectors,
      specified by the logical array SELECT.

 SELECT
   SELECT is LOGICAL array, dimension (N)
   If HOWMNY='S', SELECT specifies the eigenvectors to be
   computed.  The eigenvector corresponding to the j-th
   eigenvalue is computed if SELECT(j) = .TRUE..
   Not referenced if HOWMNY = 'A' or 'B'.

 N
   N is INTEGER
```

```
  The order of the matrices S and P.  N >= 0.

S
  S is COMPLEX*16 array, dimension (LDS,N)
  The upper triangular matrix S from a generalized Schur
  factorization, as computed by ZHGEQZ.

LDS
  LDS is INTEGER
  The leading dimension of array S.  LDS >= max(1,N).

P
  P is COMPLEX*16 array, dimension (LDP,N)
  The upper triangular matrix P from a generalized Schur
  factorization, as computed by ZHGEQZ.  P must have real
  diagonal elements.

LDP
  LDP is INTEGER
  The leading dimension of array P.  LDP >= max(1,N).

VL
  VL is COMPLEX*16 array, dimension (LDVL,MM)
  On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must
  contain an N-by-N matrix Q (usually the unitary matrix Q
  of left Schur vectors returned by ZHGEQZ).
  On exit, if SIDE = 'L' or 'B', VL contains:
  if HOWMNY = 'A', the matrix Y of left eigenvectors of (S,P);
  if HOWMNY = 'B', the matrix Q*Y;
  if HOWMNY = 'S', the left eigenvectors of (S,P) specified by
      SELECT, stored consecutively in the columns of
      VL, in the same order as their eigenvalues.
  Not referenced if SIDE = 'R'.

LDVL
  LDVL is INTEGER
  The leading dimension of array VL.  LDVL >= 1, and if
  SIDE = 'L' or 'l' or 'B' or 'b', LDVL >= N.

VR
  VR is COMPLEX*16 array, dimension (LDVR,MM)
  On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must
  contain an N-by-N matrix Q (usually the unitary matrix Z
  of right Schur vectors returned by ZHGEQZ).
  On exit, if SIDE = 'R' or 'B', VR contains:
  if HOWMNY = 'A', the matrix X of right eigenvectors of (S,P);
  if HOWMNY = 'B', the matrix Z*X;
  if HOWMNY = 'S', the right eigenvectors of (S,P) specified by
       SELECT, stored consecutively in the columns of
       VR, in the same order as their eigenvalues.
```

```
  Not referenced if SIDE = 'L'.

LDVR
  LDVR is INTEGER
  The leading dimension of the array VR.  LDVR >= 1, and if
  SIDE = 'R' or 'B', LDVR >= N.

MM
  MM is INTEGER
  The number of columns in the arrays VL and/or VR. MM >= M.

M
  M is INTEGER
  The number of columns in the arrays VL and/or VR actually
  used to store the eigenvectors.  If HOWMNY = 'A' or 'B', M
  is set to N.  Each selected eigenvector occupies one column.

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine ztgexc (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
          IFST, ILST, INFO)
          ZTGEXC

Function/Subroutine Documentation
   subroutine ztgexc (logical WANTQ, logical WANTZ, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, complex*16, dimension( ldq, * ) Q, integer LDQ,
       complex*16, dimension( ldz, * ) Z, integer LDZ, integer IFST, integer
       ILST, integer INFO)
       ZTGEXC

Purpose:
   ZTGEXC reorders the generalized Schur decomposition of a complex
   matrix pair (A,B), using an unitary equivalence transformation
   (A, B) := Q * (A, B) * Z**H, so that the diagonal block of (A, B) with
   row index IFST is moved to row ILST.

   (A, B) must be in generalized Schur canonical form, that is, A and
   B are both upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.

   Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
   Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the upper triangular matrix A in the pair (A, B).
   On exit, the updated matrix A.

 LDA
   LDA is INTEGER
```

```
  The leading dimension of the array A. LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB,N)
  On entry, the upper triangular matrix B in the pair (A, B).
  On exit, the updated matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

Q
  Q is COMPLEX*16 array, dimension (LDZ,N)
  On entry, if WANTQ = .TRUE., the unitary matrix Q.
  On exit, the updated matrix Q.
  If WANTQ = .FALSE., Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q. LDQ >= 1;
  If WANTQ = .TRUE., LDQ >= N.

Z
  Z is COMPLEX*16 array, dimension (LDZ,N)
  On entry, if WANTZ = .TRUE., the unitary matrix Z.
  On exit, the updated matrix Z.
  If WANTZ = .FALSE., Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z. LDZ >= 1;
  If WANTZ = .TRUE., LDZ >= N.

IFST
  IFST is INTEGER

ILST
  ILST is INTEGER
  Specify the reordering of the diagonal blocks of (A, B).
  The block with row index IFST is moved to row ILST, by a
  sequence of swapping between adjacent blocks.

INFO
  INFO is INTEGER
  =0:  Successful exit.
  <0:  if INFO = -i, the i-th argument had an illegal value.
  =1:  The transformed matrix pair (A, B) would be too far
       from generalized Schur form; the problem is ill-
       conditioned. (A, B) may have been partially reordered,
       and ILST points to the first row of the current
```

position of the block being moved.

SYNOPSIS
   Functions/Subroutines
       subroutine dgesc2 (N, A, LDA, RHS, IPIV, JPIV, SCALE)
           DGESC2 solves a system of linear equations using the LU
           factorization with complete pivoting computed by sgetc2.

Function/Subroutine Documentation
   subroutine dgesc2 (integer N, double precision, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) RHS, integer, dimension(
       * ) IPIV, integer, dimension( * ) JPIV, double precision SCALE)
       DGESC2 solves a system of linear equations using the LU factorization
       with complete pivoting computed by sgetc2.

Purpose:
   DGESC2 solves a system of linear equations

   A * X = scale* RHS

   with a general N-by-N matrix A using the LU factorization with
   complete pivoting computed by DGETC2.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the  LU part of the factorization of the n-by-n
   matrix A computed by DGETC2:  A = P * L * U * Q

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1, N).

 RHS
   RHS is DOUBLE PRECISION array, dimension (N).
   On entry, the right hand side vector b.
   On exit, the solution vector X.

 IPIV
   IPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= i <= N, row i of the
   matrix has been interchanged with row IPIV(i).
```

```
 JPIV
   JPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= j <= N, column j of the
   matrix has been interchanged with column JPIV(j).

 SCALE
   SCALE is DOUBLE PRECISION
   On exit, SCALE contains the scale factor. SCALE is chosen
   0 <= SCALE <= 1 to prevent owerflow in the solution.
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dgetc2 (N, A, LDA, IPIV, JPIV, INFO)
           DGETC2 computes the LU factorization with complete pivoting of the
           general n-by-n matrix.

Function/Subroutine Documentation
   subroutine dgetc2 (integer N, double precision, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer, dimension( * )
       JPIV, integer INFO)
       DGETC2 computes the LU factorization with complete pivoting of the
       general n-by-n matrix.

Purpose:
   DGETC2 computes an LU factorization with complete pivoting of the
   n-by-n matrix A. The factorization has the form A = P * L * U * Q,
   where P and Q are permutation matrices, L is lower triangular with
   unit diagonal elements and U is upper triangular.

   This is the Level 2 BLAS algorithm.

Parameters:

 N
```

```
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the n-by-n matrix A to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U*Q; the unit diagonal elements of L are not stored.
  If U(k, k) appears to be less than SMIN, U(k, k) is given the
  value of SMIN, i.e., giving a nonsingular perturbed system.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension(N).
  The pivot indices; for 1 <= i <= N, row i of the
  matrix has been interchanged with row IPIV(i).

JPIV
  JPIV is INTEGER array, dimension(N).
  The pivot indices; for 1 <= j <= N, column j of the
  matrix has been interchanged with column JPIV(j).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, U(k, k) is likely to produce owerflow if
       we try to solve for x in Ax = b. So U is perturbed to
       avoid the overflow.
```

SYNOPSIS
   Functions/Subroutines
       double precision function dlange (NORM, M, N, A, LDA, WORK)
           DLANGE returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of a general
           rectangular matrix.

Function/Subroutine Documentation
   double precision function dlange (character NORM, integer M, integer N,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) WORK)
       DLANGE returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of a general rectangular
       matrix.

Purpose:
```

```
  DLANGE  returns the value of the one norm,  or the Frobenius norm, or
  the  infinity norm,  or the  element of  largest absolute value  of a
  real matrix A.

  Returns:

          DLANGE

              DLANGE = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                       (
                       ( norm1(A),         NORM = '1', 'O' or 'o'
                       (
                       ( normI(A),         NORM = 'I' or 'i'
                       (
                       ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

  where  norm1  denotes the  one norm of a matrix (maximum column sum),
  normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
  normF  denotes the  Frobenius norm of a matrix (square root of sum of
  squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in DLANGE as described above.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.  When M = 0,
   DLANGE is set to zero.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.  When N = 0,
   DLANGE is set to zero.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The m by n matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
   where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dlaqge (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
           DLAQGE scales a general rectangular matrix, using row and column
           scaling factors computed by sgeequ.

Function/Subroutine Documentation
   subroutine dlaqge (integer M, integer N, double precision, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) R, double
       precision, dimension( * ) C, double precision ROWCND, double precision
       COLCND, double precision AMAX, character EQUED)
       DLAQGE scales a general rectangular matrix, using row and column
       scaling factors computed by sgeequ.

Purpose:
   DLAQGE equilibrates a general M by N matrix A using the row and
   column scaling factors in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the M by N matrix A.
   On exit, the equilibrated matrix.  See EQUED for the form of
   the equilibrated matrix.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).

 R
   R is DOUBLE PRECISION array, dimension (M)
   The row scale factors for A.

 C
   C is DOUBLE PRECISION array, dimension (N)
   The column scale factors for A.
```

```
 ROWCND
   ROWCND is DOUBLE PRECISION
   Ratio of the smallest R(i) to the largest R(i).

 COLCND
   COLCND is DOUBLE PRECISION
   Ratio of the smallest C(i) to the largest C(i).

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:
   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.

SYNOPSIS
   Functions/Subroutines
       subroutine dtgex2 (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1,
           N1, N2, WORK, LWORK, INFO)
           DTGEX2 swaps adjacent diagonal blocks in an upper (quasi)
           triangular matrix pair by an orthogonal equivalence transformation.

Function/Subroutine Documentation
   subroutine dtgex2 (logical WANTQ, logical WANTZ, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( ldq, *
       ) Q, integer LDQ, double precision, dimension( ldz, * ) Z, integer LDZ,
       integer J1, integer N1, integer N2, double precision, dimension( * )
       WORK, integer LWORK, integer INFO)
       DTGEX2 swaps adjacent diagonal blocks in an upper (quasi) triangular
       matrix pair by an orthogonal equivalence transformation.
```

```
Purpose:
   DTGEX2 swaps adjacent diagonal blocks (A11, B11) and (A22, B22)
   of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair
   (A, B) by an orthogonal equivalence transformation.

   (A, B) must be in generalized real Schur canonical form (as returned
   by DGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2
   diagonal blocks. B is upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.

   Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
   Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is DOUBLE PRECISION array, dimensions (LDA,N)
   On entry, the matrix A in the pair (A, B).
   On exit, the updated matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is DOUBLE PRECISION array, dimensions (LDB,N)
   On entry, the matrix B in the pair (A, B).
   On exit, the updated matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,N).
```

```
Q
  Q is DOUBLE PRECISION array, dimension (LDQ,N)
  On entry, if WANTQ = .TRUE., the orthogonal matrix Q.
  On exit, the updated matrix Q.
  Not referenced if WANTQ = .FALSE..

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q. LDQ >= 1.
  If WANTQ = .TRUE., LDQ >= N.

Z
  Z is DOUBLE PRECISION array, dimension (LDZ,N)
  On entry, if WANTZ =.TRUE., the orthogonal matrix Z.
  On exit, the updated matrix Z.
  Not referenced if WANTZ = .FALSE..

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z. LDZ >= 1.
  If WANTZ = .TRUE., LDZ >= N.

J1
  J1 is INTEGER
  The index to the first block (A11, B11). 1 <= J1 <= N.

N1
  N1 is INTEGER
  The order of the first block (A11, B11). N1 = 0, 1 or 2.

N2
  N2 is INTEGER
  The order of the second block (A22, B22). N2 = 0, 1 or 2.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)).

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >=  MAX( 1, N*(N2+N1), (N2+N1)*(N2+N1)*2 )

INFO
  INFO is INTEGER
  =0: Successful exit
  >0: If INFO = 1, the transformed matrix (A, B) would be
      too far from generalized Schur form; the blocks are
      not swapped and (A, B) and (Q, Z) are unchanged.
      The problem of swapping is too ill-conditioned.
  <0: If INFO = -16: LWORK is too small. Appropriate value
```

```
      for LWORK is returned in WORK(1).

Further Details:

   In the current code both weak and strong stability tests are
   performed. The user can omit the strong stability test by changing
   the internal logical parameter WANDS to .FALSE..
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgesc2 (N, A, LDA, RHS, IPIV, JPIV, SCALE)
           SGESC2 solves a system of linear equations using the LU
           factorization with complete pivoting computed by sgetc2.

Function/Subroutine Documentation
   subroutine sgesc2 (integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( * ) RHS, integer, dimension( * ) IPIV, integer,
       dimension( * ) JPIV, real SCALE)
       SGESC2 solves a system of linear equations using the LU factorization
       with complete pivoting computed by sgetc2.

Purpose:
   SGESC2 solves a system of linear equations

           A * X = scale* RHS

   with a general N-by-N matrix A using the LU factorization with
   complete pivoting computed by SGETC2.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the  LU part of the factorization of the n-by-n
   matrix A computed by SGETC2:  A = P * L * U * Q

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1, N).

 RHS
   RHS is REAL array, dimension (N).
   On entry, the right hand side vector b.
   On exit, the solution vector X.

 IPIV
   IPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= i <= N, row i of the
   matrix has been interchanged with row IPIV(i).
```

```
 JPIV
   JPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= j <= N, column j of the
   matrix has been interchanged with column JPIV(j).

 SCALE
   SCALE is REAL
   On exit, SCALE contains the scale factor. SCALE is chosen
   0 <= SCALE <= 1 to prevent owerflow in the solution.
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgetc2 (N, A, LDA, IPIV, JPIV, INFO)
           SGETC2 computes the LU factorization with complete pivoting of the
           general n-by-n matrix.

Function/Subroutine Documentation
   subroutine sgetc2 (integer N, real, dimension( lda, * ) A, integer LDA,
       integer, dimension( * ) IPIV, integer, dimension( * ) JPIV, integer
       INFO)
       SGETC2 computes the LU factorization with complete pivoting of the
       general n-by-n matrix.

Purpose:
   SGETC2 computes an LU factorization with complete pivoting of the
   n-by-n matrix A. The factorization has the form A = P * L * U * Q,
   where P and Q are permutation matrices, L is lower triangular with
   unit diagonal elements and U is upper triangular.

   This is the Level 2 BLAS algorithm.

Parameters:

 N
   N is INTEGER
```

```
  The order of the matrix A. N >= 0.

A
  A is REAL array, dimension (LDA, N)
  On entry, the n-by-n matrix A to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U*Q; the unit diagonal elements of L are not stored.
  If U(k, k) appears to be less than SMIN, U(k, k) is given the
  value of SMIN, i.e., giving a nonsingular perturbed system.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension(N).
  The pivot indices; for 1 <= i <= N, row i of the
  matrix has been interchanged with row IPIV(i).

JPIV
  JPIV is INTEGER array, dimension(N).
  The pivot indices; for 1 <= j <= N, column j of the
  matrix has been interchanged with column JPIV(j).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, U(k, k) is likely to produce owerflow if
       we try to solve for x in Ax = b. So U is perturbed to
       avoid the overflow.
```

SYNOPSIS
   Functions/Subroutines
       real function slange (NORM, M, N, A, LDA, WORK)
           SLANGE returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of a general
           rectangular matrix.

Function/Subroutine Documentation
   real function slange (character NORM, integer M, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) WORK)
       SLANGE returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of a general rectangular
       matrix.

Purpose:
   SLANGE  returns the value of the one norm,  or the Frobenius norm, or
```

```
  the  infinity norm,  or the  element of  largest absolute value  of a
  real matrix A.

 Returns:

  SLANGE
       SLANGE = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

  where  norm1  denotes the  one norm of a matrix (maximum column sum),
  normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
  normF  denotes the  Frobenius norm of a matrix (square root of sum of
  squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
  NORM is CHARACTER*1
  Specifies the value to be returned in SLANGE as described above.

 M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.  When M = 0,
  SLANGE is set to zero.

 N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.  When N = 0,
  SLANGE is set to zero.

 A
  A is REAL array, dimension (LDA,N)
  The m by n matrix A.

 LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(M,1).

 WORK
  WORK is REAL array, dimension (MAX(1,LWORK)),
  where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slaqge (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
```

```
          SLAQGE scales a general rectangular matrix, using row and column
          scaling factors computed by sgeequ.

Function/Subroutine Documentation
   subroutine slaqge (integer M, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) R, real, dimension( * ) C, real
       ROWCND, real COLCND, real AMAX, character EQUED)
       SLAQGE scales a general rectangular matrix, using row and column
       scaling factors computed by sgeequ.

Purpose:
   SLAQGE equilibrates a general M by N matrix A using the row and
   column scaling factors in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the M by N matrix A.
   On exit, the equilibrated matrix.  See EQUED for the form of
   the equilibrated matrix.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).

 R
   R is REAL array, dimension (M)
   The row scale factors for A.

 C
   C is REAL array, dimension (N)
   The column scale factors for A.

 ROWCND
   ROWCND is REAL
   Ratio of the smallest R(i) to the largest R(i).

 COLCND
   COLCND is REAL
   Ratio of the smallest C(i) to the largest C(i).
```

```
 AMAX
   AMAX is REAL
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:

   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       subroutine stgex2 (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1,
           N1, N2, WORK, LWORK, INFO)
           STGEX2 swaps adjacent diagonal blocks in an upper (quasi)
           triangular matrix pair by an orthogonal equivalence transformation.

Function/Subroutine Documentation
   subroutine stgex2 (logical WANTQ, logical WANTZ, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( ldq, * ) Q, integer LDQ, real, dimension(
       ldz, * ) Z, integer LDZ, integer J1, integer N1, integer N2, real,
       dimension( * ) WORK, integer LWORK, integer INFO)
       STGEX2 swaps adjacent diagonal blocks in an upper (quasi) triangular
       matrix pair by an orthogonal equivalence transformation.

Purpose:
   STGEX2 swaps adjacent diagonal blocks (A11, B11) and (A22, B22)
   of size 1-by-1 or 2-by-2 in an upper (quasi) triangular matrix pair
   (A, B) by an orthogonal equivalence transformation.

   (A, B) must be in generalized real Schur canonical form (as returned
   by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2
   diagonal blocks. B is upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.
```

```
   Q(in) * A(in) * Z(in)**T = Q(out) * A(out) * Z(out)**T
   Q(in) * B(in) * Z(in)**T = Q(out) * B(out) * Z(out)**T

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is REAL arrays, dimensions (LDA,N)
   On entry, the matrix A in the pair (A, B).
   On exit, the updated matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is REAL arrays, dimensions (LDB,N)
   On entry, the matrix B in the pair (A, B).
   On exit, the updated matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,N).

 Q
   Q is REAL array, dimension (LDZ,N)
   On entry, if WANTQ = .TRUE., the orthogonal matrix Q.
   On exit, the updated matrix Q.
   Not referenced if WANTQ = .FALSE..

 LDQ
   LDQ is INTEGER
   The leading dimension of the array Q. LDQ >= 1.
   If WANTQ = .TRUE., LDQ >= N.

 Z
```

```
  Z is REAL array, dimension (LDZ,N)
  On entry, if WANTZ =.TRUE., the orthogonal matrix Z.
  On exit, the updated matrix Z.
  Not referenced if WANTZ = .FALSE..

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z. LDZ >= 1.
  If WANTZ = .TRUE., LDZ >= N.

J1
  J1 is INTEGER
  The index to the first block (A11, B11). 1 <= J1 <= N.

N1
  N1 is INTEGER
  The order of the first block (A11, B11). N1 = 0, 1 or 2.

N2
  N2 is INTEGER
  The order of the second block (A22, B22). N2 = 0, 1 or 2.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK)).

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  LWORK >=  MAX( N*(N2+N1), (N2+N1)*(N2+N1)*2 )

INFO
  INFO is INTEGER
  =0: Successful exit
  >0: If INFO = 1, the transformed matrix (A, B) would be
      too far from generalized Schur form; the blocks are
      not swapped and (A, B) and (Q, Z) are unchanged.
      The problem of swapping is too ill-conditioned.
  <0: If INFO = -16: LWORK is too small. Appropriate value
      for LWORK is returned in WORK(1).

Further Details:

  In the current code both weak and strong stability tests are
  performed. The user can omit the strong stability test by changing
  the internal logical parameter WANDS to .FALSE.. See ref. [2] for details.

SYNOPSIS
   Functions/Subroutines
       subroutine cgesc2 (N, A, LDA, RHS, IPIV, JPIV, SCALE)
           CGESC2 solves a system of linear equations using the LU
           factorization with complete pivoting computed by sgetc2.

Function/Subroutine Documentation
   subroutine cgesc2 (integer N, complex, dimension( lda, * ) A, integer LDA,
       complex, dimension( * ) RHS, integer, dimension( * ) IPIV, integer,
       dimension( * ) JPIV, real SCALE)
       CGESC2 solves a system of linear equations using the LU factorization
       with complete pivoting computed by sgetc2.

Purpose:
   CGESC2 solves a system of linear equations

      A * X = scale* RHS

   with a general N-by-N matrix A using the LU factorization with
   complete pivoting computed by CGETC2.

Parameters:

 N
   N is INTEGER
   The number of columns of the matrix A.

 A
   A is COMPLEX array, dimension (LDA, N)
   On entry, the  LU part of the factorization of the n-by-n
   matrix A computed by CGETC2:  A = P * L * U * Q

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1, N).

 RHS
   RHS is COMPLEX array, dimension N.
   On entry, the right hand side vector b.
   On exit, the solution vector X.

 IPIV
   IPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= i <= N, row i of the
   matrix has been interchanged with row IPIV(i).
```

```
 JPIV
   JPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= j <= N, column j of the
   matrix has been interchanged with column JPIV(j).

 SCALE
   SCALE is REAL
   On exit, SCALE contains the scale factor. SCALE is chosen
   0 <= SCALE <= 1 to prevent owerflow in the solution.
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgetc2 (N, A, LDA, IPIV, JPIV, INFO)
           CGETC2 computes the LU factorization with complete pivoting of the
           general n-by-n matrix.

Function/Subroutine Documentation
   subroutine cgetc2 (integer N, complex, dimension( lda, * ) A, integer LDA,
       integer, dimension( * ) IPIV, integer, dimension( * ) JPIV, integer
       INFO)
       CGETC2 computes the LU factorization with complete pivoting of the
       general n-by-n matrix.

Purpose:
   CGETC2 computes an LU factorization, using complete pivoting, of the
   n-by-n matrix A. The factorization has the form A = P * L * U * Q,
```

```
  where P and Q are permutation matrices, L is lower triangular with
  unit diagonal elements and U is upper triangular.

  This is a level 1 BLAS version of the algorithm.

Parameters:

N
  N is INTEGER
  The order of the matrix A. N >= 0.

A
  A is COMPLEX array, dimension (LDA, N)
  On entry, the n-by-n matrix to be factored.
  On exit, the factors L and U from the factorization
  A = P*L*U*Q; the unit diagonal elements of L are not stored.
  If U(k, k) appears to be less than SMIN, U(k, k) is given the
  value of SMIN, giving a nonsingular perturbed system.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1, N).

IPIV
  IPIV is INTEGER array, dimension (N).
  The pivot indices; for 1 <= i <= N, row i of the
  matrix has been interchanged with row IPIV(i).

JPIV
  JPIV is INTEGER array, dimension (N).
  The pivot indices; for 1 <= j <= N, column j of the
  matrix has been interchanged with column JPIV(j).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, U(k, k) is likely to produce overflow if
       one tries to solve for x in Ax = b. So U is perturbed
       to avoid the overflow.
```

SYNOPSIS
   Functions/Subroutines
       real function clange (NORM, M, N, A, LDA, WORK)
           CLANGE returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of a general
           rectangular matrix.

Function/Subroutine Documentation
```

```
   real function clange (character NORM, integer M, integer N, complex,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) WORK)
       CLANGE returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of a general rectangular
       matrix.

Purpose:
   CLANGE  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   complex matrix A.

 Returns:

 CLANGE
   CLANGE = ( max(abs(A(i,j))), NORM = 'M' or 'm'
            (
            ( norm1(A),         NORM = '1', 'O' or 'o'
            (
            ( normI(A),         NORM = 'I' or 'i'
            (
            ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in CLANGE as described above.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.  When M = 0,
   CLANGE is set to zero.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.  When N = 0,
   CLANGE is set to zero.

 A
   A is COMPLEX array, dimension (LDA,N)
   The m by n matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).
```

```
 WORK
   WORK is REAL array, dimension (MAX(1,LWORK)),
   where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.
```

Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine claqge (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
           CLAQGE scales a general rectangular matrix, using row and column
           scaling factors computed by sgeequ.

Function/Subroutine Documentation
   subroutine claqge (integer M, integer N, complex, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) R, real, dimension( * ) C, real
       ROWCND, real COLCND, real AMAX, character EQUED)
       CLAQGE scales a general rectangular matrix, using row and column
       scaling factors computed by sgeequ.

Purpose:
   CLAQGE equilibrates a general M by N matrix A using the row and
   column scaling factors in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the M by N matrix A.
   On exit, the equilibrated matrix.  See EQUED for the form of
   the equilibrated matrix.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).

 R
   R is REAL array, dimension (M)
   The row scale factors for A.

 C
   C is REAL array, dimension (N)
   The column scale factors for A.

 ROWCND
   ROWCND is REAL
   Ratio of the smallest R(i) to the largest R(i).

 COLCND
   COLCND is REAL
   Ratio of the smallest C(i) to the largest C(i).

 AMAX
   AMAX is REAL
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:

   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctgex2 (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1,
           INFO)
           CTGEX2 swaps adjacent diagonal blocks in an upper (quasi)
           triangular matrix pair by an unitary equivalence transformation.

Function/Subroutine Documentation
   subroutine ctgex2 (logical WANTQ, logical WANTZ, integer N, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldb, * ) B,
       integer LDB, complex, dimension( ldq, * ) Q, integer LDQ, complex,
       dimension( ldz, * ) Z, integer LDZ, integer J1, integer INFO)
       CTGEX2 swaps adjacent diagonal blocks in an upper (quasi) triangular
       matrix pair by an unitary equivalence transformation.

Purpose:
   CTGEX2 swaps adjacent diagonal 1 by 1 blocks (A11,B11) and (A22,B22)
   in an upper triangular matrix pair (A, B) by an unitary equivalence
   transformation.

   (A, B) must be in generalized Schur canonical form, that is, A and
   B are both upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are updated.

   Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
   Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is COMPLEX arrays, dimensions (LDA,N)
   On entry, the matrix A in the pair (A, B).
   On exit, the updated matrix A.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is COMPLEX arrays, dimensions (LDB,N)
   On entry, the matrix B in the pair (A, B).
   On exit, the updated matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,N).

 Q
   Q is COMPLEX array, dimension (LDZ,N)
   If WANTQ = .TRUE, on entry, the unitary matrix Q. On exit,
   the updated matrix Q.
   Not referenced if WANTQ = .FALSE..

 LDQ
   LDQ is INTEGER
   The leading dimension of the array Q. LDQ >= 1;
   If WANTQ = .TRUE., LDQ >= N.

 Z
   Z is COMPLEX array, dimension (LDZ,N)
   If WANTZ = .TRUE, on entry, the unitary matrix Z. On exit,
   the updated matrix Z.
   Not referenced if WANTZ = .FALSE..

 LDZ
   LDZ is INTEGER
   The leading dimension of the array Z. LDZ >= 1;
   If WANTZ = .TRUE., LDZ >= N.

 J1
   J1 is INTEGER
   The index to the first block (A11, B11).

 INFO
   INFO is INTEGER
   =0:  Successful exit.
   =1:  The transformed matrix pair (A, B) would be too far
        from generalized Schur form; the problem is ill-conditioned.

Further Details:

   In the current code both weak and strong stability tests are
   performed. The user can omit the strong stability test by changing
```

the internal logical parameter WANDS to .FALSE.. See ref. [2] for details.

SYNOPSIS
   Functions/Subroutines
       subroutine zgesc2 (N, A, LDA, RHS, IPIV, JPIV, SCALE)
           ZGESC2 solves a system of linear equations using the LU
           factorization with complete pivoting computed by sgetc2.

Function/Subroutine Documentation
   subroutine zgesc2 (integer N, complex*16, dimension( lda, * ) A, integer
       LDA, complex*16, dimension( * ) RHS, integer, dimension( * ) IPIV,
       integer, dimension( * ) JPIV, double precision SCALE)
       ZGESC2 solves a system of linear equations using the LU factorization
       with complete pivoting computed by sgetc2.

Purpose:
   ZGESC2 solves a system of linear equations

      A * X = scale* RHS

   with a general N-by-N matrix A using the LU factorization with
   complete pivoting computed by ZGETC2.

Parameters:

 N
   N is INTEGER
   The number of columns of the matrix A.

 A
   A is COMPLEX*16 array, dimension (LDA, N)
   On entry, the  LU part of the factorization of the n-by-n
   matrix A computed by ZGETC2:  A = P * L * U * Q

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1, N).

 RHS
   RHS is COMPLEX*16 array, dimension N.
   On entry, the right hand side vector b.
   On exit, the solution vector X.

 IPIV
   IPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= i <= N, row i of the
   matrix has been interchanged with row IPIV(i).
```

```
 JPIV
   JPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= j <= N, column j of the
   matrix has been interchanged with column JPIV(j).

 SCALE
   SCALE is DOUBLE PRECISION
   On exit, SCALE contains the scale factor. SCALE is chosen
   0 <= SCALE <= 1 to prevent owerflow in the solution.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgetc2 (N, A, LDA, IPIV, JPIV, INFO)
           ZGETC2 computes the LU factorization with complete pivoting of the
           general n-by-n matrix.

Function/Subroutine Documentation
   subroutine zgetc2 (integer N, complex*16, dimension( lda, * ) A, integer
       LDA, integer, dimension( * ) IPIV, integer, dimension( * ) JPIV,
       integer INFO)
       ZGETC2 computes the LU factorization with complete pivoting of the
       general n-by-n matrix.

Purpose:
   ZGETC2 computes an LU factorization, using complete pivoting, of the
   n-by-n matrix A. The factorization has the form A = P * L * U * Q,
```

```
   where P and Q are permutation matrices, L is lower triangular with
   unit diagonal elements and U is upper triangular.

   This is a level 1 BLAS version of the algorithm.

Parameters:

 N
   N is INTEGER
   The order of the matrix A. N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA, N)
   On entry, the n-by-n matrix to be factored.
   On exit, the factors L and U from the factorization
   A = P*L*U*Q; the unit diagonal elements of L are not stored.
   If U(k, k) appears to be less than SMIN, U(k, k) is given the
   value of SMIN, giving a nonsingular perturbed system.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1, N).

 IPIV
   IPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= i <= N, row i of the
   matrix has been interchanged with row IPIV(i).

 JPIV
   JPIV is INTEGER array, dimension (N).
   The pivot indices; for 1 <= j <= N, column j of the
   matrix has been interchanged with column JPIV(j).

 INFO
   INFO is INTEGER
   = 0: successful exit
   > 0: if INFO = k, U(k, k) is likely to produce overflow if
        one tries to solve for x in Ax = b. So U is perturbed
        to avoid the overflow.

SYNOPSIS
   Functions/Subroutines
       double precision function zlange (NORM, M, N, A, LDA, WORK)
           ZLANGE returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of a general
           rectangular matrix.

Function/Subroutine Documentation
   double precision function zlange (character NORM, integer M, integer N,
```

```
      complex*16, dimension( lda, * ) A, integer LDA, double precision,
      dimension( * ) WORK)
      ZLANGE returns the value of the 1-norm, Frobenius norm, infinity-norm,
      or the largest absolute value of any element of a general rectangular
      matrix.

Purpose:
   ZLANGE  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   complex matrix A.

 Returns:

 ZLANGE
   ZLANGE = ( max(abs(A(i,j))), NORM = 'M' or 'm'
            (
            ( norm1(A),         NORM = '1', 'O' or 'o'
            (
            ( normI(A),         NORM = 'I' or 'i'
            (
            ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in ZLANGE as described above.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.  When M = 0,
   ZLANGE is set to zero.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.  When N = 0,
   ZLANGE is set to zero.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The m by n matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).
```

```
 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
   where LWORK >= M when NORM = 'I'; otherwise, WORK is not referenced.
```

zlaqge examples
====================================================================

====================================================================
Man Page Details
====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zlaqge (M, N, A, LDA, R, C, ROWCND, COLCND, AMAX, EQUED)
           ZLAQGE scales a general rectangular matrix, using row and column
           scaling factors computed by sgeequ.

Function/Subroutine Documentation
   subroutine zlaqge (integer M, integer N, complex*16, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) R, double precision,
       dimension( * ) C, double precision ROWCND, double precision COLCND,
       double precision AMAX, character EQUED)
       ZLAQGE scales a general rectangular matrix, using row and column
       scaling factors computed by sgeequ.

Purpose:
   ZLAQGE equilibrates a general M by N matrix A using the row and
   column scaling factors in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the M by N matrix A.
   On exit, the equilibrated matrix.  See EQUED for the form of
   the equilibrated matrix.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(M,1).
```

```
 R
   R is DOUBLE PRECISION array, dimension (M)
   The row scale factors for A.

 C
   C is DOUBLE PRECISION array, dimension (N)
   The column scale factors for A.

 ROWCND
   ROWCND is DOUBLE PRECISION
   Ratio of the smallest R(i) to the largest R(i).

 COLCND
   COLCND is DOUBLE PRECISION
   Ratio of the smallest C(i) to the largest C(i).

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:

   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.

SYNOPSIS
   Functions/Subroutines
       subroutine ztgex2 (WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ, J1,
           INFO)
           ZTGEX2 swaps adjacent diagonal blocks in an upper (quasi)
           triangular matrix pair by an unitary equivalence transformation.
```

```
Function/Subroutine Documentation
   subroutine ztgex2 (logical WANTQ, logical WANTZ, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, complex*16, dimension( ldq, * ) Q, integer LDQ,
       complex*16, dimension( ldz, * ) Z, integer LDZ, integer J1, integer
       INFO)
       ZTGEX2 swaps adjacent diagonal blocks in an upper (quasi) triangular
       matrix pair by an unitary equivalence transformation.

Purpose:
   ZTGEX2 swaps adjacent diagonal 1 by 1 blocks (A11,B11) and (A22,B22)
   in an upper triangular matrix pair (A, B) by an unitary equivalence
   transformation.

   (A, B) must be in generalized Schur canonical form, that is, A and
   B are both upper triangular.

   Optionally, the matrices Q and Z of generalized Schur vectors are
   updated.

   Q(in) * A(in) * Z(in)**H = Q(out) * A(out) * Z(out)**H
   Q(in) * B(in) * Z(in)**H = Q(out) * B(out) * Z(out)**H

Parameters:

 WANTQ
   WANTQ is LOGICAL
   .TRUE. : update the left transformation matrix Q;
   .FALSE.: do not update Q.

 WANTZ
   WANTZ is LOGICAL
   .TRUE. : update the right transformation matrix Z;
   .FALSE.: do not update Z.

 N
   N is INTEGER
   The order of the matrices A and B. N >= 0.

 A
   A is COMPLEX*16 arrays, dimensions (LDA,N)
   On entry, the matrix A in the pair (A, B).
   On exit, the updated matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is COMPLEX*16 arrays, dimensions (LDB,N)
```

```
   On entry, the matrix B in the pair (A, B).
   On exit, the updated matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,N).

 Q
   Q is COMPLEX*16 array, dimension (LDZ,N)
   If WANTQ = .TRUE, on entry, the unitary matrix Q. On exit,
   the updated matrix Q.
   Not referenced if WANTQ = .FALSE..

 LDQ
   LDQ is INTEGER
   The leading dimension of the array Q. LDQ >= 1;
   If WANTQ = .TRUE., LDQ >= N.

 Z
   Z is COMPLEX*16 array, dimension (LDZ,N)
   If WANTZ = .TRUE, on entry, the unitary matrix Z. On exit,
   the updated matrix Z.
   Not referenced if WANTZ = .FALSE..

 LDZ
   LDZ is INTEGER
   The leading dimension of the array Z. LDZ >= 1;
   If WANTZ = .TRUE., LDZ >= N.

 J1
   J1 is INTEGER
   The index to the first block (A11, B11).

 INFO
   INFO is INTEGER
   =0:  Successful exit.
   =1:  The transformed matrix pair (A, B) would be too far
        from generalized Schur form; the problem is ill-conditioned.

Further Details:

   In the current code both weak and strong stability tests are
   performed. The user can omit the strong stability test by changing
   the internal logical parameter WANDS to .FALSE.. See ref. [2] for details.

SYNOPSIS
   Functions/Subroutines
       subroutine dgbsv (N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
            DGBSV computes the solution to system of linear equations A * X =
           B for GB matrices (simple driver)

Function/Subroutine Documentation
   subroutine dgbsv (integer N, integer KL, integer KU, integer NRHS, double
       precision, dimension( ldab, * ) AB, integer LDAB, integer, dimension( *
       ) IPIV, double precision, dimension( ldb, * ) B, integer LDB, integer
       INFO)
        DGBSV computes the solution to system of linear equations A * X = B
       for GB matrices (simple driver)

Purpose:
   DGBSV computes the solution to a real system of linear equations
   A * X = B, where A is a band matrix of order N with KL subdiagonals
   and KU superdiagonals, and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as A = L * U, where L is a product of permutation
   and unit lower triangular matrices with KL subdiagonals, and U is
   upper triangular with KL+KU superdiagonals.  The factored form of A
   is then used to solve the system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 AB
```

```
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows KL+1 to
  2*KL+KU+1; rows 1 to KL of the array need not be set.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL)
  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices that define the permutation matrix P;
  row i of the matrix was interchanged with row IPIV(i).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
        has been completed, but the factor U is exactly
        singular, and the solution has not been computed.

Further Details:

  The band storage scheme is illustrated by the following example, when
  M = N = 6, KL = 2, KU = 1:

       On entry:                       On exit:

           *    *    *    +    +    +       *    *    *   u14  u25  u36
           *    *    +    +    +    +       *    *   u13  u24  u35  u46
           *   a12  a23  a34  a45  a56       *   u12  u23  u34  u45  u56
          a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
          a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
```

```
          a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine dgbsvx (FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB,
          IPIV, EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK,
          INFO)
           DGBSVX computes the solution to system of linear equations A * X =
          B for GB matrices

Function/Subroutine Documentation
   subroutine dgbsvx (character FACT, character TRANS, integer N, integer KL,
       integer KU, integer NRHS, double precision, dimension( ldab, * ) AB,
       integer LDAB, double precision, dimension( ldafb, * ) AFB, integer
       LDAFB, integer, dimension( * ) IPIV, character EQUED, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( ldx, *
       ) X, integer LDX, double precision RCOND, double precision, dimension(
       * ) FERR, double precision, dimension( * ) BERR, double precision,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
        DGBSVX computes the solution to system of linear equations A * X = B
       for GB matrices

Purpose:
   DGBSVX uses the LU factorization to compute the solution to a real
   system of linear equations A * X = B, A**T * X = B, or A**H * X = B,
   where A is a band matrix of order N with KL subdiagonals and KU
   superdiagonals, and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:
   The following steps are performed by this subroutine:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
         A = L * U,
      where L is a product of permutation and unit lower triangular
      matrices with KL subdiagonals, and U is upper triangular with
      KL+KU superdiagonals.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
```

```
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AFB and IPIV contain the factored form of
           A.  If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           AB, AFB, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AFB and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AFB and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
```

```
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then A must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by DGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AFB is an output argument and on exit
  returns details of the LU factorization of A.

  If FACT = 'E', then AFB is an output argument and on exit
  returns details of the LU factorization of the equilibrated
  matrix A (see the description of AB for the form of the
  equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = L*U
```

```
  as computed by DGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by
  diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
  overwritten by diag(C)*B.

LDB
  LDB is INTEGER
```

```
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)
  On exit, WORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If WORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  WORK(1) contains the reciprocal pivot growth factor for the
```

```
  leading INFO columns of A.

 IWORK
  IWORK is INTEGER array, dimension (N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  U(i,i) is exactly zero.  The factorization
         has been completed, but the factor U is exactly
         singular, so the solution and error bounds
         could not be computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
         precision, meaning that the matrix is singular
         to working precision.  Nevertheless, the
         solution and error bounds are computed because
         there are a number of situations where the
         computed solution can be more accurate than the
         value of RCOND would suggest.
```

       DGBSVXX computes the solution to system of linear equations A * X = B
      for GB matrices

Purpose:
   DGBSVXX uses the LU factorization to compute the solution to a
   double precision system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   DGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DGBSVXX would itself produce.

Description:
   The following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:

      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as

      A = P * L * U,

      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.
```

```
   3. If some U(i,i)=0, so that U is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND). If the reciprocal of the condition number is less
      than machine precision, the routine still goes on to solve for X
      and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

      Some optional parameters are bundled in the PARAMS array.  These
      settings determine how refinement is performed, but often the
      defaults are acceptable.  If the defaults are acceptable, users
      can pass NPARAMS = 0 which prevents the source code from accessing
      the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.
```

```
KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then AB must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by DGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
```

```
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by DGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
```

```
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
```

```
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In DGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                   max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
```

```
      sqrt(n) * dlamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated normwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * dlamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*A, where S scales each row by a power of the
      radix so all absolute row sums of Z are approximately 1.

 ERR_BNDS_COMP
   ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
   For each right-hand side, this array contains information about
   various error bounds and condition numbers corresponding to the
   componentwise relative error, which is defined as follows:

   Componentwise relative error in the ith solution vector:
                   abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

   The array is indexed by the right-hand side i (on which the
   componentwise relative error depends), and the type of error
   information as described below. There currently are up to three
   pieces of information returned for each right-hand side. If
   componentwise accuracy is not requested (PARAMS(3) = 0.0), then
   ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
   the first (:,N_ERR_BNDS) entries are returned.

   The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
   right-hand side.

   The second index in ERR_BNDS_COMP(:,err) contains the following
   three fields:
   err = 1 "Trust/don't trust" boolean. Trust the answer if the
      reciprocal condition number is less than the threshold
      sqrt(n) * dlamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
      sqrt(n) * dlamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * dlamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
```

```
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension (NPARAMS)
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
```

```
      guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbsv (N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
            SGBSV computes the solution to system of linear equations A * X =
           B for GB matrices (simple driver)

Function/Subroutine Documentation
   subroutine sgbsv (integer N, integer KL, integer KU, integer NRHS, real,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       real, dimension( ldb, * ) B, integer LDB, integer INFO)
        SGBSV computes the solution to system of linear equations A * X = B
       for GB matrices (simple driver)

Purpose:
   SGBSV computes the solution to a real system of linear equations
   A * X = B, where A is a band matrix of order N with KL subdiagonals
   and KU superdiagonals, and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as A = L * U, where L is a product of permutation
   and unit lower triangular matrices with KL subdiagonals, and U is
   upper triangular with KL+KU superdiagonals.  The factored form of A
   is then used to solve the system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
```

```
  On entry, the matrix A in band storage, in rows KL+1 to
  2*KL+KU+1; rows 1 to KL of the array need not be set.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL)
  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

 LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices that define the permutation matrix P;
  row i of the matrix was interchanged with row IPIV(i).

 B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

 LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
        has been completed, but the factor U is exactly
        singular, and the solution has not been computed.

Further Details:

  The band storage scheme is illustrated by the following example, when
  M = N = 6, KL = 2, KU = 1:

       On entry:                      On exit:

           *    *    *    +    +    +       *    *    *   u14  u25  u36
           *    *    +    +    +    +       *    *   u13  u24  u35  u46
           *   a12  a23  a34  a45  a56       *   u12  u23  u34  u45  u56
          a11  a22  a33  a44  a55  a66      u11  u22  u33  u44  u55  u66
          a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
          a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *
```

```
Array elements marked * are not used by the routine; elements marked
+ need not be set on entry, but are required by the routine to store
elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbsvx (FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB,
```

```
          IPIV, EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK,
          INFO)
           SGBSVX computes the solution to system of linear equations A * X =
          B for GB matrices

Function/Subroutine Documentation
   subroutine sgbsvx (character FACT, character TRANS, integer N, integer KL,
       integer KU, integer NRHS, real, dimension( ldab, * ) AB, integer LDAB,
       real, dimension( ldafb, * ) AFB, integer LDAFB, integer, dimension( * )
       IPIV, character EQUED, real, dimension( * ) R, real, dimension( * ) C,
       real, dimension( ldb, * ) B, integer LDB, real, dimension( ldx, * ) X,
       integer LDX, real RCOND, real, dimension( * ) FERR, real, dimension( *
       ) BERR, real, dimension( * ) WORK, integer, dimension( * ) IWORK,
       integer INFO)
        SGBSVX computes the solution to system of linear equations A * X = B
       for GB matrices

Purpose:
   SGBSVX uses the LU factorization to compute the solution to a real
   system of linear equations A * X = B, A**T * X = B, or A**H * X = B,
   where A is a band matrix of order N with KL subdiagonals and KU
   superdiagonals, and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:

   The following steps are performed by this subroutine:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
         A = L * U,
      where L is a product of permutation and unit lower triangular
      matrices with KL subdiagonals, and U is upper triangular with
      KL+KU superdiagonals.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
```

```
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates
      for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AFB and IPIV contain the factored form of
      A.  If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by R and C.
      AB, AFB, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AFB and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AFB and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
```

```
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is REAL array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then A must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is REAL array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by SGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AFB is an output argument and on exit
  returns details of the LU factorization of A.

  If FACT = 'E', then AFB is an output argument and on exit
  returns details of the LU factorization of the equilibrated
  matrix A (see the description of AB for the form of the
  equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = L*U
```

```
  as computed by SGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by
  diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
  overwritten by diag(C)*B.

LDB
  LDB is INTEGER
```

```
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (3*N)
  On exit, WORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If WORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  WORK(1) contains the reciprocal pivot growth factor for the
```

```
  leading INFO columns of A.

 IWORK
  IWORK is INTEGER array, dimension (N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  U(i,i) is exactly zero.  The factorization
     has been completed, but the factor U is exactly
     singular, so the solution and error bounds
     could not be computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
```

       SGBSVXX computes the solution to system of linear equations A * X = B
      for GB matrices

Purpose:
   SGBSVXX uses the LU factorization to compute the solution to a
   real system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SGBSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as

      A = P * L * U,

      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.
```

```
   3. If some U(i,i)=0, so that U is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND). If the reciprocal of the condition number is less
      than machine precision, the routine still goes on to solve for X
      and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by R and C.
      A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.
```

```
KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is REAL array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then AB must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is REAL array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by SGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
```

```
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by SGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
```

```
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
```

```
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In SGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
```

```
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated normwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * slamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*A, where S scales each row by a power of the
      radix so all absolute row sums of Z are approximately 1.

 ERR_BNDS_COMP
   ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
   For each right-hand side, this array contains information about
   various error bounds and condition numbers corresponding to the
   componentwise relative error, which is defined as follows:

   Componentwise relative error in the ith solution vector:
                   abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

   The array is indexed by the right-hand side i (on which the
   componentwise relative error depends), and the type of error
   information as described below. There currently are up to three
   pieces of information returned for each right-hand side. If
   componentwise accuracy is not requested (PARAMS(3) = 0.0), then
   ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
   the first (:,N_ERR_BNDS) entries are returned.

   The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
   right-hand side.

   The second index in ERR_BNDS_COMP(:,err) contains the following
   three fields:
   err = 1 "Trust/don't trust" boolean. Trust the answer if the
      reciprocal condition number is less than the threshold
      sqrt(n) * slamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
      sqrt(n) * slamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * slamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
```

```
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
```

```
= 0:  Successful exit. The solution to every right-hand side is
guaranteed.
< 0:  If INFO = -i, the i-th argument had an illegal value
> 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
   has been completed, but the factor U is exactly singular, so
   the solution and error bounds could not be computed. RCOND = 0
   is returned.
= N+J: The solution corresponding to the Jth right-hand side is
   not guaranteed. The solutions corresponding to other right-
   hand sides K with K > J may not be guaranteed as well, but
   only the first such right-hand side is reported. If a small
   componentwise error is not requested (PARAMS(3) = 0.0) then
   the Jth right-hand side is the first with a normwise error
   bound that is not guaranteed (the smallest J such
   that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
   the Jth right-hand side is the first with either a normwise or
   componentwise error bound that is not guaranteed (the smallest
   J such that either ERR_BNDS_NORM(J,1) = 0.0 or
   ERR_BNDS_COMP(J,1) = 0.0). See the definition of
   ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
   about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine cgbsv (N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
            CGBSV computes the solution to system of linear equations A * X =
           B for GB matrices (simple driver)

Function/Subroutine Documentation
   subroutine cgbsv (integer N, integer KL, integer KU, integer NRHS, complex,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, integer INFO)
        CGBSV computes the solution to system of linear equations A * X = B
       for GB matrices (simple driver)

Purpose:
   CGBSV computes the solution to a complex system of linear equations
   A * X = B, where A is a band matrix of order N with KL subdiagonals
   and KU superdiagonals, and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as A = L * U, where L is a product of permutation
   and unit lower triangular matrices with KL subdiagonals, and U is
   upper triangular with KL+KU superdiagonals.  The factored form of A
   is then used to solve the system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 AB
```

```
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows KL+1 to
  2*KL+KU+1; rows 1 to KL of the array need not be set.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL)
  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices that define the permutation matrix P;
  row i of the matrix was interchanged with row IPIV(i).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
        has been completed, but the factor U is exactly
        singular, and the solution has not been computed.

The band storage scheme is illustrated by the following example, when
    M = N = 6, KL = 2, KU = 1:

    On entry:                       On exit:

        *    *    *    +    +    +       *    *    *   u14  u25  u36
        *    *    +    +    +    +       *    *   u13  u24  u35  u46
        *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
       a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
       a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
       a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *
```

```
Array elements marked * are not used by the routine; elements marked
+ need not be set on entry, but are required by the routine to store
elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine cgbsvx (FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB,
          IPIV, EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK,
          INFO)
           CGBSVX computes the solution to system of linear equations A * X =
          B for GB matrices

Function/Subroutine Documentation
   subroutine cgbsvx (character FACT, character TRANS, integer N, integer KL,
       integer KU, integer NRHS, complex, dimension( ldab, * ) AB, integer
       LDAB, complex, dimension( ldafb, * ) AFB, integer LDAFB, integer,
       dimension( * ) IPIV, character EQUED, real, dimension( * ) R, real,
       dimension( * ) C, complex, dimension( ldb, * ) B, integer LDB, complex,
       dimension( ldx, * ) X, integer LDX, real RCOND, real, dimension( * )
       FERR, real, dimension( * ) BERR, complex, dimension( * ) WORK, real,
       dimension( * ) RWORK, integer INFO)
        CGBSVX computes the solution to system of linear equations A * X = B
       for GB matrices

Purpose:
   CGBSVX uses the LU factorization to compute the solution to a complex
   system of linear equations A * X = B, A**T * X = B, or A**H * X = B,
   where A is a band matrix of order N with KL subdiagonals and KU
   superdiagonals, and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:
   The following steps are performed by this subroutine:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

   TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as A = L * U,
      where L is a product of permutation and unit lower triangular
      matrices with KL subdiagonals, and U is upper triangular with
      KL+KU superdiagonals.

   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
```

```
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AFB and IPIV contain the factored form of
           A.  If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           AB, AFB, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AFB and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AFB and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
```

```
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then A must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by CGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AFB is an output argument and on exit
  returns details of the LU factorization of A.

  If FACT = 'E', then AFB is an output argument and on exit
  returns details of the LU factorization of the equilibrated
  matrix A (see the description of AB for the form of the
  equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
```

```
  contains the pivot indices from the factorization A = L*U
  as computed by CGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.

LDB
  LDB is INTEGER
```

```
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (N)
  On exit, RWORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If RWORK(1) is much less than 1, then the stability
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
```

```
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  RWORK(1) contains the reciprocal pivot growth factor for the
  leading INFO columns of A.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
         <= N:  U(i,i) is exactly zero.  The factorization
                has been completed, but the factor U is exactly
                singular, so the solution and error bounds
                could not be computed. RCOND = 0 is returned.
         = N+1: U is nonsingular, but RCOND is less than machine
                precision, meaning that the matrix is singular
                to working precision.  Nevertheless, the
                solution and error bounds are computed because
                there are a number of situations where the
                computed solution can be more accurate than the
                value of RCOND would suggest.

       CGBSVXX computes the solution to system of linear equations A * X = B
      for GB matrices

Purpose:
   CGBSVXX uses the LU factorization to compute the solution to a
   complex system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CGBSVXX would itself produce.

Description:
   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

   TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
   TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
   TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as
```

```
   A = P * L * U,

   where P is a permutation matrix, L is a unit lower triangular
   matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
   routine returns with INFO = i. Otherwise, the factored form of A
   is used to estimate the condition number of the matrix A (see
   argument RCOND). If the reciprocal of the condition number is less
   than machine precision, the routine still goes on to solve for X
   and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
   the routine will use iterative refinement to try to get a small
   error and error bounds.  Refinement calculates the residual to at
   least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
   that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by R and C.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
            copied to AF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)
```

```
N
  N is INTEGER
  The number of linear equations, i.e., the order of the
  matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then AB must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by CGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.
```

```
  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by SGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
```

```
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
```

```
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-
  conditioned.

RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In SGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
             max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
```

```
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*A, where S scales each row by a power of the
           radix so all absolute row sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                    abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
           reciprocal condition number is less than the threshold
           sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
```

```
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*(A*diag(x)), where x is the solution for the
           current right-hand side and S scales each row of
           A*diag(x) by a power of the radix so all absolute row
           sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.

Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.

  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
```

```
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.

  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
        guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
        has been completed, but the factor U is exactly singular, so
        the solution and error bounds could not be computed. RCOND = 0
        is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
         not guaranteed. The solutions corresponding to other right-
         hand sides K with K > J may not be guaranteed as well, but
         only the first such right-hand side is reported. If a small
         componentwise error is not requested (PARAMS(3) = 0.0) then
         the Jth right-hand side is the first with a normwise error
         bound that is not guaranteed (the smallest J such
         that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
         the Jth right-hand side is the first with either a normwise or
         componentwise error bound that is not guaranteed (the smallest
         J such that either ERR_BNDS_NORM(J,1) = 0.0 or
         ERR_BNDS_COMP(J,1) = 0.0). See the definition of
         ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
         about all of the right-hand sides check ERR_BNDS_NORM or
         ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine zgbsv (N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB, INFO)
            ZGBSV computes the solution to system of linear equations A * X =
           B for GB matrices (simple driver)

Function/Subroutine Documentation
   subroutine zgbsv (integer N, integer KL, integer KU, integer NRHS,
       complex*16, dimension( ldab, * ) AB, integer LDAB, integer, dimension(
       * ) IPIV, complex*16, dimension( ldb, * ) B, integer LDB, integer INFO)
        ZGBSV computes the solution to system of linear equations A * X = B
       for GB matrices (simple driver)

Purpose:
   ZGBSV computes the solution to a complex system of linear equations
   A * X = B, where A is a band matrix of order N with KL subdiagonals
   and KU superdiagonals, and X and B are N-by-NRHS matrices.

   The LU decomposition with partial pivoting and row interchanges is
   used to factor A as A = L * U, where L is a product of permutation
   and unit lower triangular matrices with KL subdiagonals, and U is
   upper triangular with KL+KU superdiagonals.  The factored form of A
   is then used to solve the system of equations A * X = B.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows KL+1 to
   2*KL+KU+1; rows 1 to KL of the array need not be set.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL)
   On exit, details of the factorization: U is stored as an
   upper triangular band matrix with KL+KU superdiagonals in
   rows 1 to KL+KU+1, and the multipliers used during the
   factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
   See below for further details.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices that define the permutation matrix P;
   row i of the matrix was interchanged with row IPIV(i).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the N-by-NRHS right hand side matrix B.
   On exit, if INFO = 0, the N-by-NRHS solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, U(i,i) is exactly zero.  The factorization
         has been completed, but the factor U is exactly
         singular, and the solution has not been computed.

Further Details:

   The band storage scheme is illustrated by the following example, when
   M = N = 6, KL = 2, KU = 1:

        On entry:                       On exit:

            *    *    *    +    +    +       *    *    *   u14  u25  u36
            *    *    +    +    +    +       *    *   u13  u24  u35  u46
            *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
           a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
```

```
          a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
          a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbsvx (FACT, TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB,
           IPIV, EQUED, R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK,
           INFO)
            ZGBSVX computes the solution to system of linear equations A * X =
           B for GB matrices

Function/Subroutine Documentation
   subroutine zgbsvx (character FACT, character TRANS, integer N, integer KL,
       integer KU, integer NRHS, complex*16, dimension( ldab, * ) AB, integer
       LDAB, complex*16, dimension( ldafb, * ) AFB, integer LDAFB, integer,
       dimension( * ) IPIV, character EQUED, double precision, dimension( * )
       R, double precision, dimension( * ) C, complex*16, dimension( ldb, * )
       B, integer LDB, complex*16, dimension( ldx, * ) X, integer LDX, double
       precision RCOND, double precision, dimension( * ) FERR, double
       precision, dimension( * ) BERR, complex*16, dimension( * ) WORK, double
       precision, dimension( * ) RWORK, integer INFO)
        ZGBSVX computes the solution to system of linear equations A * X = B
       for GB matrices

Purpose:
   ZGBSVX uses the LU factorization to compute the solution to a complex
   system of linear equations A * X = B, A**T * X = B, or A**H * X = B,
   where A is a band matrix of order N with KL subdiagonals and KU
   superdiagonals, and X and B are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed by this subroutine:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
      matrix A (after equilibration if FACT = 'E') as
      A = L * U,
      where L is a product of permutation and unit lower triangular
      matrices with KL subdiagonals, and U is upper triangular with
      KL+KU superdiagonals.
```

```
   3. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AFB and IPIV contain the factored form of
      A.  If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by R and C.
      AB, AFB, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AFB and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AFB and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then A must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX*16 array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by ZGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AFB is an output argument and on exit
  returns details of the LU factorization of A.

  If FACT = 'E', then AFB is an output argument and on exit
  returns details of the LU factorization of the equilibrated
  matrix A (see the description of AB for the form of the
  equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
```

```
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = L*U
  as computed by ZGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
     replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X
  to the original system of equations.  Note that A and B are
  modified on exit if EQUED .ne. 'N', and the solution to the
  equilibrated system is inv(diag(C))*X if TRANS = 'N' and
  EQUED = 'C' or 'B', or inv(diag(R))*X if TRANS = 'T' or 'C'
  and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)
  On exit, RWORK(1) contains the reciprocal pivot growth
  factor norm(A)/norm(U). The "max absolute element" norm is
  used. If RWORK(1) is much less than 1, then the stability
```

```
  of the LU factorization of the (equilibrated) matrix A
  could be poor. This also means that the solution X, condition
  estimator RCOND, and forward error bound FERR could be
  unreliable. If factorization fails with 0<INFO<=N, then
  RWORK(1) contains the reciprocal pivot growth factor for the
  leading INFO columns of A.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  U(i,i) is exactly zero.  The factorization
     has been completed, but the factor U is exactly
     singular, so the solution and error bounds
     could not be computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

       INFO)
        ZGBSVXX computes the solution to system of linear equations A * X = B
       for GB matrices

Purpose:
   ZGBSVXX uses the LU factorization to compute the solution to a
   complex*16 system of linear equations  A * X = B,  where A is an
   N-by-N matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZGBSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZGBSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZGBSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZGBSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:

      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
```

```
      overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
      or diag(C)*B (if TRANS = 'T' or 'C').

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as

      A = P * L * U,

      where P is a permutation matrix, L is a unit lower triangular
      matrix, and U is upper triangular.

   3. If some U(i,i)=0, so that U is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND). If the reciprocal of the condition number is less
      than machine precision, the routine still goes on to solve for X
      and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
      that it solves the original system before equilibration.

      Some optional parameters are bundled in the PARAMS array.  These
      settings determine how refinement is performed, but often the
      defaults are acceptable.  If the defaults are acceptable, users
      can pass NPARAMS = 0 which prevents the source code from accessing
      the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by R and C.
      A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.
```

```
TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

  If FACT = 'F' and EQUED is not 'N', then AB must have been
  equilibrated by the scaling factors in R and/or C.  AB is not
  modified if FACT = 'F' or 'N', or if FACT = 'E' and
  EQUED = 'N' on exit.

  On exit, if EQUED .ne. 'N', A is scaled as follows:
  EQUED = 'R':  A := diag(R) * A
  EQUED = 'C':  A := A * diag(C)
  EQUED = 'B':  A := diag(R) * A * diag(C).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX*16 array, dimension (LDAFB,N)
  If FACT = 'F', then AFB is an input argument and on entry
  contains details of the LU factorization of the band matrix
  A, as computed by ZGBTRF.  U is stored as an upper triangular
```

```
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.  If EQUED .ne. 'N', then AFB is
  the factored form of the equilibrated matrix A.

  If FACT = 'N', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the factors L and U from the factorization A = P*L*U
  of the equilibrated matrix A (see the description of A for
  the form of the equilibrated matrix).

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the factorization A = P*L*U
  as computed by DGETRF; row i of the matrix was interchanged
  with row IPIV(i).

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the original matrix A.

  If FACT = 'E', then IPIV is an output argument and on exit
  contains the pivot indices from the factorization A = P*L*U
  of the equilibrated matrix A.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
     replaced by diag(R) * A * diag(C).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
```

```
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B;
  if TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is
     overwritten by diag(C)*B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit
  if EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(C))*X if TRANS = 'N' and EQUED = 'C' or 'B', or
  inv(diag(R))*X if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
```

```
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.  In DGESVX, this quantity is
  returned in WORK(1).

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                      max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.
```

```
  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').
```

```
  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)
```

```
 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  Successful exit. The solution to every right-hand side is guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine dgbbrd (VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT,
           LDPT, C, LDC, WORK, INFO)
           DGBBRD

Function/Subroutine Documentation
   subroutine dgbbrd (character VECT, integer M, integer N, integer NCC,
       integer KL, integer KU, double precision, dimension( ldab, * ) AB,
       integer LDAB, double precision, dimension( * ) D, double precision,
       dimension( * ) E, double precision, dimension( ldq, * ) Q, integer LDQ,
       double precision, dimension( ldpt, * ) PT, integer LDPT, double
       precision, dimension( ldc, * ) C, integer LDC, double precision,
       dimension( * ) WORK, integer INFO)
       DGBBRD

Purpose:
   DGBBRD reduces a real general m-by-n band matrix A to upper
   bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

   The routine computes B, and optionally forms Q or P**T, or computes
   Q**T*C for a given matrix C.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether or not the matrices Q and P**T are to be
   formed.
   = 'N': do not form Q or P**T;
   = 'Q': form Q only;
   = 'P': form P**T only;
   = 'B': form both.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NCC
```

```
  NCC is INTEGER
  The number of columns of the matrix C.  NCC >= 0.

KL
  KL is INTEGER
  The number of subdiagonals of the matrix A. KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals of the matrix A. KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the m-by-n band matrix A, stored in rows 1 to
  KL+KU+1. The j-th column of A is stored in the j-th column of
  the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).
  On exit, A is overwritten by values generated during the reduction.

LDAB
  LDAB is INTEGER
  The leading dimension of the array A. LDAB >= KL+KU+1.

D
  D is DOUBLE PRECISION array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B.

E
  E is DOUBLE PRECISION array, dimension (min(M,N)-1)
  The superdiagonal elements of the bidiagonal matrix B.

Q
  Q is DOUBLE PRECISION array, dimension (LDQ,M)
  If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q.
  If VECT = 'N' or 'P', the array Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.
  LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT
  PT is DOUBLE PRECISION array, dimension (LDPT,N)
  If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'.
  If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT
  LDPT is INTEGER
  The leading dimension of the array PT.
  LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.
```

```
C
  C is DOUBLE PRECISION array, dimension (LDC,NCC)
  On entry, an m-by-ncc matrix C.
  On exit, C is overwritten by Q**T*C.
  C is not referenced if NCC = 0.

LDC
  LDC is INTEGER
  The leading dimension of the array C.
  LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*max(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgbcon (NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK,
           IWORK, INFO)
           DGBCON

Function/Subroutine Documentation
   subroutine dgbcon (character NORM, integer N, integer KL, integer KU,
       double precision, dimension( ldab, * ) AB, integer LDAB, integer,
       dimension( * ) IPIV, double precision ANORM, double precision RCOND,
       double precision, dimension( * ) WORK, integer, dimension( * ) IWORK,
       integer INFO)
       DGBCON

Purpose:
   DGBCON estimates the reciprocal of the condition number of a real
   general band matrix A, in either the 1-norm or the infinity-norm,
   using the LU factorization computed by DGBTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
      RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.
```

```
AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

ANORM
  ANORM is DOUBLE PRECISION
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgbequ (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           DGBEQU

Function/Subroutine Documentation
   subroutine dgbequ (integer M, integer N, integer KL, integer KU, double
       precision, dimension( ldab, * ) AB, integer LDAB, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision
       ROWCND, double precision COLCND, double precision AMAX, integer INFO)
       DGBEQU

Purpose:
   DGBEQU computes row and column scalings intended to equilibrate an
   M-by-N band matrix A and reduce its condition number.  R returns the
   row scale factors and C the column scale factors, chosen to try to
   make the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

   R(i) and C(j) are restricted to be between SMLNUM = smallest safe
   number and BIGNUM = largest safe number.  Use of these scaling
   factors is not guaranteed to reduce the condition number of A but
   works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is DOUBLE PRECISION array, dimension (LDAB,N)
```

```
  The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
  column of A is stored in the j-th column of the array AB as
  follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

R
  R is DOUBLE PRECISION array, dimension (M)
  If INFO = 0, or INFO > M, R contains the row scale factors for A.

C
  C is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, C contains the column scale factors for A.

ROWCND
  ROWCND is DOUBLE PRECISION
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is DOUBLE PRECISION
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
    <= M:  the i-th row of A is exactly zero
    >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgbequb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           DGBEQUB

Function/Subroutine Documentation
   subroutine dgbequb (integer M, integer N, integer KL, integer KU, double
       precision, dimension( ldab, * ) AB, integer LDAB, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision
       ROWCND, double precision COLCND, double precision AMAX, integer INFO)
       DGBEQUB

Purpose:
   DGBEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from DGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.
```

```
N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array A.  LDAB >= max(1,M).

R
  R is DOUBLE PRECISION array, dimension (M)
  If INFO = 0 or INFO > M, R contains the row scale factors for A.

C
  C is DOUBLE PRECISION array, dimension (N)
  If INFO = 0,  C contains the column scale factors for A.

ROWCND
  ROWCND is DOUBLE PRECISION
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is DOUBLE PRECISION
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
```

```
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i,  and i is
     <= M:  the i-th row of A is exactly zero
     >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgbrfs (TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, IWORK, INFO)
           DGBRFS

Function/Subroutine Documentation
   subroutine dgbrfs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, double precision, dimension( ldab, * ) AB, integer LDAB,
       double precision, dimension( ldafb, * ) AFB, integer LDAFB, integer,
       dimension( * ) IPIV, double precision, dimension( ldb, * ) B, integer
       LDB, double precision, dimension( ldx, * ) X, integer LDX, double
       precision, dimension( * ) FERR, double precision, dimension( * ) BERR,
       double precision, dimension( * ) WORK, integer, dimension( * ) IWORK,
       integer INFO)
       DGBRFS

Purpose:
   DGBRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is banded, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  The original band matrix A, stored in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from DGBTRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGBTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).
```

```
 FERR
   FERR is DOUBLE PRECISION array, dimension (NRHS)
   The estimated forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is DOUBLE PRECISION array, dimension (3*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.

      INFO)
      DGBRFSX

Purpose:
   DGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
                the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.
```

```
KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  The original band matrix A, stored in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from DGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
```

```
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
```

```
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                   max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.
```

```
ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.
```

```
PARAMS
  PARAMS is DOUBLE PRECISION array, dimension (NPARAMS)
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
    componentwise error is not requested (PARAMS(3) = 0.0) then
```

```
the Jth right-hand side is the first with a normwise error
bound that is not guaranteed (the smallest J such
that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
the Jth right-hand side is the first with either a normwise or
componentwise error bound that is not guaranteed (the smallest
J such that either ERR_BNDS_NORM(J,1) = 0.0 or
ERR_BNDS_COMP(J,1) = 0.0). See the definition of
ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine dgbtf2 (M, N, KL, KU, AB, LDAB, IPIV, INFO)
          DGBTF2 computes the LU factorization of a general band matrix using
          the unblocked version of the algorithm.

Function/Subroutine Documentation
   subroutine dgbtf2 (integer M, integer N, integer KL, integer KU, double
       precision, dimension( ldab, * ) AB, integer LDAB, integer, dimension( *
       ) IPIV, integer INFO)
       DGBTF2 computes the LU factorization of a general band matrix using the
       unblocked version of the algorithm.

Purpose:
   DGBTF2 computes an LU factorization of a real m-by-n band matrix A
   using partial pivoting with row interchanges.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is DOUBLE PRECISION array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows KL+1 to
   2*KL+KU+1; rows 1 to KL of the array need not be set.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

   On exit, details of the factorization: U is stored as an
   upper triangular band matrix with KL+KU superdiagonals in
   rows 1 to KL+KU+1, and the multipliers used during the
   factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
   See below for further details.

 LDAB
```

```
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
        has been completed, but the factor U is exactly
        singular, and division by zero will occur if it is used
        to solve a system of equations.

Further Details:

   The band storage scheme is illustrated by the following example, when
   M = N = 6, KL = 2, KU = 1:

        On entry:                       On exit:

            *    *    *    +    +    +       *    *    *   u14  u25  u36
            *    *    +    +    +    +       *    *   u13  u24  u35  u46
            *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
           a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
           a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
           a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U, because of fill-in resulting from the row
   interchanges.

SYNOPSIS
   Functions/Subroutines
       subroutine dgbtrf (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           DGBTRF

Function/Subroutine Documentation
   subroutine dgbtrf (integer M, integer N, integer KL, integer KU, double
       precision, dimension( ldab, * ) AB, integer LDAB, integer, dimension( *
       ) IPIV, integer INFO)
       DGBTRF

Purpose:
   DGBTRF computes an LU factorization of a real m-by-n band matrix A
   using partial pivoting with row interchanges.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
```

```
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows KL+1 to
  2*KL+KU+1; rows 1 to KL of the array need not be set.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
       has been completed, but the factor U is exactly
       singular, and division by zero will occur if it is used
       to solve a system of equations.

Further Details:

  The band storage scheme is illustrated by the following example, when
  M = N = 6, KL = 2, KU = 1:

       On entry:                       On exit:

           *    *    *    +    +    +       *    *    *   u14  u25  u36
           *    *    +    +    +    +       *    *   u13  u24  u35  u46
           *   a12  a23  a34  a45  a56       *   u12  u23  u34  u45  u56
          a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
          a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
```

```
          a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgbtrs (TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB,
           INFO)
           DGBTRS

Function/Subroutine Documentation
   subroutine dgbtrs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, double precision, dimension( ldab, * ) AB, integer LDAB,
       integer, dimension( * ) IPIV, double precision, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       DGBTRS

Purpose:
   DGBTRS solves a system of linear equations
      A * X = B  or  A**T * X = B
   with a general band matrix A using the LU factorization computed by DGBTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B  (No transpose)
   = 'T':  A**T* X = B  (Transpose)
   = 'C':  A**T* X = B  (Conjugate transpose = Transpose)

 N
```

```
  N is INTEGER
  The order of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dggbak (JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV,
           INFO)
           DGGBAK

Function/Subroutine Documentation
   subroutine dggbak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, double precision, dimension( * ) LSCALE, double precision,
       dimension( * ) RSCALE, integer M, double precision, dimension( ldv, * )
       V, integer LDV, integer INFO)
       DGGBAK

Purpose:
   DGGBAK forms the right or left eigenvectors of a real generalized
   eigenvalue problem A*x = lambda*B*x, by backward transformation on
```

```
   the computed eigenvectors of the balanced pair of matrices output by DGGBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N':  do nothing, return immediately;
   = 'P':  do backward transformation for permutation only;
   = 'S':  do backward transformation for scaling only;
   = 'B':  do backward transformations for both permutation and scaling.
   JOB must be the same as the argument JOB supplied to DGGBAL.

 SIDE
   SIDE is CHARACTER*1
   = 'R':  V contains right eigenvectors;
   = 'L':  V contains left eigenvectors.

 N
   N is INTEGER
   The number of rows of the matrix V.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   The integers ILO and IHI determined by DGGBAL.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 LSCALE
   LSCALE is DOUBLE PRECISION array, dimension (N)
   Details of the permutations and/or scaling factors applied
   to the left side of A and B, as returned by DGGBAL.

 RSCALE
   RSCALE is DOUBLE PRECISION array, dimension (N)
   Details of the permutations and/or scaling factors applied
   to the right side of A and B, as returned by DGGBAL.

 M
   M is INTEGER
   The number of columns of the matrix V.  M >= 0.

 V
   V is DOUBLE PRECISION array, dimension (LDV,M)
   On entry, the matrix of right or left eigenvectors to be
   transformed, as returned by DTGEVC.
   On exit, V is overwritten by the transformed eigenvectors.
```

```
 LDV
   LDV is INTEGER
   The leading dimension of the matrix V. LDV >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dggbal (JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
           WORK, INFO)
           DGGBAL

Function/Subroutine Documentation
   subroutine dggbal (character JOB, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision, dimension( ldb, * ) B,
       integer LDB, integer ILO, integer IHI, double precision, dimension( * )
       LSCALE, double precision, dimension( * ) RSCALE, double precision,
       dimension( * ) WORK, integer INFO)
       DGGBAL

Purpose:
   DGGBAL balances a pair of general real matrices (A,B).  This
   involves, first, permuting A and B by similarity transformations to
   isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N
   elements on the diagonal; and second, applying a diagonal similarity
   transformation to rows and columns ILO to IHI to make the rows
   and columns as close in norm as possible. Both steps are optional.

   Balancing may reduce the 1-norm of the matrices, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors in the
   generalized eigenvalue problem A*x = lambda*B*x.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A and B:
   = 'N':  none:  simply set ILO = 1, IHI = N, LSCALE(I) = 1.0
   and RSCALE(I) = 1.0 for i = 1,...,N.
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the input matrix A.
   On exit,  A is overwritten by the balanced matrix.
   If JOB = 'N', A is not referenced.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB,N)
  On entry, the input matrix B.
  On exit,  B is overwritten by the balanced matrix.
  If JOB = 'N', B is not referenced.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If P(j) is the index of the
  row interchanged with row j, and D(j)
  is the scaling factor applied to row j, then
  LSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

RSCALE
  RSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If P(j) is the index of the
  column interchanged with column j, and D(j)
  is the scaling factor applied to column j, then
  LSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

WORK
  WORK is DOUBLE PRECISION array, dimension (lwork)
  lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and
```

```
  at least 1 when JOB = 'N' or 'P'.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dla_gbamv (TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX,
           BETA, Y, INCY)
           DLA_GBAMV performs a matrix-vector operation to calculate error
           bounds.

Function/Subroutine Documentation
   subroutine dla_gbamv (integer TRANS, integer M, integer N, integer KL,
       integer KU, double precision ALPHA, double precision, dimension( ldab,
```

```
      * ) AB, integer LDAB, double precision, dimension( * ) X, integer INCX,
      double precision BETA, double precision, dimension( * ) Y, integer
      INCY)
      DLA_GBAMV performs a matrix-vector operation to calculate error bounds.

Purpose:
   DLA_GBAMV  performs one of the matrix-vector operations

        y := alpha*abs(A)*abs(x) + beta*abs(y),
   or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
   Unchanged on exit.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.
   Unchanged on exit.

 KL
   KL is INTEGER
```

```
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

ALPHA
  ALPHA is DOUBLE PRECISION
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

AB
  AB is DOUBLE PRECISION array of DIMENSION ( LDAB, n )
  Before entry, the leading m by n part of the array AB must
  contain the matrix of coefficients.
  Unchanged on exit.

LDAB
  LDAB is INTEGER
  On entry, LDA specifies the first dimension of AB as declared
  in the calling (sub) program. LDAB must be at least max( 1, m ).
  Unchanged on exit.

X
  X is DOUBLE PRECISION array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is DOUBLE PRECISION
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is DOUBLE PRECISION array, dimension
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
```

```
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       double precision function dla_gbrcond (TRANS, N, KL, KU, AB, LDAB, AFB,
           LDAFB, IPIV, CMODE, C, INFO, WORK, IWORK)
           DLA_GBRCOND estimates the Skeel condition number for a general
           banded matrix.

Function/Subroutine Documentation
   double precision function dla_gbrcond (character TRANS, integer N, integer
       KL, integer KU, double precision, dimension( ldab, * ) AB, integer
       LDAB, double precision, dimension( ldafb, * ) AFB, integer LDAFB,
       integer, dimension( * ) IPIV, integer CMODE, double precision,
       dimension( * ) C, integer INFO, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK)
       DLA_GBRCOND estimates the Skeel condition number for a general banded
       matrix.

Purpose:
   DLA_GBRCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
```

```
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by DGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is DOUBLE PRECISION array, dimension (5*N).
```

```
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.
```

       DLA_GBRFSX_EXTENDED improves the computed solution to a system of
       linear equations for general banded matrices by performing extra-
       precise iterative refinement and provides error bounds and backward
       error estimates for the solution.

Purpose:
   DLA_GBRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by DGBRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

   PREC_TYPE

   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 TRANS_TYPE
   TRANS_TYPE is INTEGER
   Specifies the transposition operation on A.
   The value is defined by ILATRANS(T) where T is a CHARACTER and
   T    = 'N':  No transpose
        = 'T':  Transpose
        = 'C':  Conjugate transpose

 N
```

```
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the N-by-N matrix AB.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDBA >= max(1,N).

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  The factors L and U from the factorization
  A = P*L*U as computed by DGBTRF.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AF.  LDAFB >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by DGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
```

```
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is DOUBLE PRECISION array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by DGBTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
```

```
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension
  (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.
```

```
  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.

DY
  DY is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.
```

```
 ITHRESH
   ITHRESH is INTEGER
   The maximum number of residual computations allowed for
   refinement. The default is 10. For 'aggressive' set to 100 to
   permit convergence using approximate factorizations or
   factorizations other than LU. If the factorization uses a
   technique other than Gaussian elimination, the guarantees in
   ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

 RTHRESH
   RTHRESH is DOUBLE PRECISION
   Determines when to stop refinement if the error estimate stops
   decreasing. Refinement will stop when the next solution no longer
   satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
   the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
   default value is 0.5. For 'aggressive' set to 0.9 to permit
   convergence on extremely ill-conditioned matrices. See LAWN 165
   for more details.

 DZ_UB
   DZ_UB is DOUBLE PRECISION
   Determines when to start considering componentwise convergence.
   Componentwise convergence is only considered after each component
   of the solution Y is stable, which we definte as the relative
   change in each component being less than DZ_UB. The default value
   is 0.25, requiring the first bit to be stable. See LAWN 165 for
   more details.

 IGNORE_CWISE
   IGNORE_CWISE is LOGICAL
   If .TRUE. then ignore componentwise convergence. Default value
   is .FALSE..

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   < 0:  if INFO = -i, the ith argument to DGBTRS had an illegal value
