SYNOPSIS
   Functions/Subroutines
       double precision function dla_gbrpvgrw (N, KL, KU, NCOLS, AB, LDAB,
           AFB, LDAFB)
           DLA_GBRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a general banded matrix.

Function/Subroutine Documentation
   double precision function dla_gbrpvgrw (integer N, integer KL, integer KU,
       integer NCOLS, double precision, dimension( ldab, * ) AB, integer LDAB,
       double precision, dimension( ldafb, * ) AFB, integer LDAFB)
       DLA_GBRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a general banded matrix.

Purpose:
   DLA_GBRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A.  NCOLS >= 0.

 AB
   AB is DOUBLE PRECISION array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)
```

```
LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

SYNOPSIS
   Functions/Subroutines
       subroutine dorgbr (VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
           DORGBR

Function/Subroutine Documentation
   subroutine dorgbr (character VECT, integer M, integer N, integer K, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) TAU, double precision, dimension( * ) WORK, integer
       LWORK, integer INFO)
       DORGBR

Purpose:
   DORGBR generates one of the real orthogonal matrices Q or P**T
   determined by DGEBRD when reducing a real matrix A to bidiagonal
   form: A = Q * B * P**T.  Q and P**T are defined as products of
   elementary reflectors H(i) or G(i) respectively.

   If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q
   is of order M:
   if m >= k, Q = H(1) H(2) . . . H(k) and DORGBR returns the first n
   columns of Q, where m >= n >= k;
   if m < k, Q = H(1) H(2) . . . H(m-1) and DORGBR returns Q as an
   M-by-M matrix.

   If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**T
   is of order N:
   if k < n, P**T = G(k) . . . G(2) G(1) and DORGBR returns the first m
   rows of P**T, where n >= m >= k;
   if k >= n, P**T = G(n-1) . . . G(2) G(1) and DORGBR returns P**T as
   an N-by-N matrix.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether the matrix Q or the matrix P**T is
   required, as defined in the transformation applied by DGEBRD:
   = 'Q':  generate Q;
   = 'P':  generate P**T.

 M
   M is INTEGER
   The number of rows of the matrix Q or P**T to be returned.
   M >= 0.

 N
   N is INTEGER
```

```
  The number of columns of the matrix Q or P**T to be returned.
  N >= 0.
  If VECT = 'Q', M >= N >= min(M,K);
  if VECT = 'P', N >= M >= min(N,K).

K
  K is INTEGER
  If VECT = 'Q', the number of columns in the original M-by-K
  matrix reduced by DGEBRD.
  If VECT = 'P', the number of rows in the original K-by-N
  matrix reduced by DGEBRD.
  K >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the vectors which define the elementary reflectors,
  as returned by DGEBRD.
  On exit, the M-by-N matrix Q or P**T.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

TAU
  TAU is DOUBLE PRECISION array, dimension
     (min(M,K)) if VECT = 'Q'
     (min(N,K)) if VECT = 'P'
  TAU(i) must contain the scalar factor of the elementary
  reflector H(i) or G(i), which determines Q or P**T, as
  returned by DGEBRD in its array argument TAUQ or TAUP.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= max(1,min(M,N)).
  For optimum performance LWORK >= min(M,N)*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbbrd (VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT,
           LDPT, C, LDC, WORK, INFO)
           SGBBRD

Function/Subroutine Documentation
   subroutine sgbbrd (character VECT, integer M, integer N, integer NCC,
       integer KL, integer KU, real, dimension( ldab, * ) AB, integer LDAB,
       real, dimension( * ) D, real, dimension( * ) E, real, dimension( ldq, *
       ) Q, integer LDQ, real, dimension( ldpt, * ) PT, integer LDPT, real,
       dimension( ldc, * ) C, integer LDC, real, dimension( * ) WORK, integer
       INFO)
       SGBBRD

Purpose:
   SGBBRD reduces a real general m-by-n band matrix A to upper
   bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

   The routine computes B, and optionally forms Q or P**T, or computes
   Q**T*C for a given matrix C.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether or not the matrices Q and P**T are to be
   formed.
   = 'N': do not form Q or P**T;
   = 'Q': form Q only;
   = 'P': form P**T only;
   = 'B': form both.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NCC
   NCC is INTEGER
   The number of columns of the matrix C.  NCC >= 0.
```

```
KL
  KL is INTEGER
  The number of subdiagonals of the matrix A. KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals of the matrix A. KU >= 0.

AB
  AB is REAL array, dimension (LDAB,N)
  On entry, the m-by-n band matrix A, stored in rows 1 to
  KL+KU+1. The j-th column of A is stored in the j-th column of
  the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).
  On exit, A is overwritten by values generated during the reduction.

LDAB
  LDAB is INTEGER
  The leading dimension of the array A. LDAB >= KL+KU+1.

D
  D is REAL array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B.

E
  E is REAL array, dimension (min(M,N)-1)
  The superdiagonal elements of the bidiagonal matrix B.

Q
  Q is REAL array, dimension (LDQ,M)
  If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q.
  If VECT = 'N' or 'P', the array Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.
  LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT
  PT is REAL array, dimension (LDPT,N)
  If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'.
  If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT
  LDPT is INTEGER
  The leading dimension of the array PT.
  LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C
  C is REAL array, dimension (LDC,NCC)
```

```
  On entry, an m-by-ncc matrix C.
  On exit, C is overwritten by Q**T*C.
  C is not referenced if NCC = 0.

LDC
  LDC is INTEGER
  The leading dimension of the array C.
  LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK
  WORK is REAL array, dimension (2*max(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbcon (NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK,
           IWORK, INFO)
           SGBCON

Function/Subroutine Documentation
   subroutine sgbcon (character NORM, integer N, integer KL, integer KU, real,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       real ANORM, real RCOND, real, dimension( * ) WORK, integer, dimension(
       * ) IWORK, integer INFO)
       SGBCON

Purpose:
   SGBCON estimates the reciprocal of the condition number of a real
   general band matrix A, in either the 1-norm or the infinity-norm,
   using the LU factorization computed by SGBTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
   Details of the LU factorization of the band matrix A, as
   computed by SGBTRF.  U is stored as an upper triangular band
```

```
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

ANORM
  ANORM is REAL
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is REAL
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK
  WORK is REAL array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbequ (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           SGBEQU

Function/Subroutine Documentation
   subroutine sgbequ (integer M, integer N, integer KL, integer KU, real,
       dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) R, real,
       dimension( * ) C, real ROWCND, real COLCND, real AMAX, integer INFO)
       SGBEQU

Purpose:
   SGBEQU computes row and column scalings intended to equilibrate an
   M-by-N band matrix A and reduce its condition number.  R returns the
   row scale factors and C the column scale factors, chosen to try to
   make the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

   R(i) and C(j) are restricted to be between SMLNUM = smallest safe
   number and BIGNUM = largest safe number.  Use of these scaling
   factors is not guaranteed to reduce the condition number of A but
   works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
   The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
   column of A is stored in the j-th column of the array AB as
   follows:
   AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).
```

```
LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

R
  R is REAL array, dimension (M)
  If INFO = 0, or INFO > M, R contains the row scale factors for A.

C
  C is REAL array, dimension (N)
  If INFO = 0, C contains the column scale factors for A.

ROWCND
  ROWCND is REAL
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is REAL
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
     <= M:  the i-th row of A is exactly zero
     >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbequb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           SGBEQUB

Function/Subroutine Documentation
   subroutine sgbequb (integer M, integer N, integer KL, integer KU, real,
       dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) R, real,
       dimension( * ) C, real ROWCND, real COLCND, real AMAX, integer INFO)
       SGBEQUB

Purpose:
   SGBEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from SGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
```

```
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array A.  LDAB >= max(1,M).

R
  R is REAL array, dimension (M)
  If INFO = 0 or INFO > M, R contains the row scale factors for A.

C
  C is REAL array, dimension (N)
  If INFO = 0,  C contains the column scale factors for A.

ROWCND
  ROWCND is REAL
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is REAL
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i,  and i is
     <= M:  the i-th row of A is exactly zero
     >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbrfs (TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, IWORK, INFO)
           SGBRFS

Function/Subroutine Documentation
   subroutine sgbrfs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, real, dimension( ldab, * ) AB, integer LDAB, real,
       dimension( ldafb, * ) AFB, integer LDAFB, integer, dimension( * ) IPIV,
       real, dimension( ldb, * ) B, integer LDB, real, dimension( ldx, * ) X,
       integer LDX, real, dimension( * ) FERR, real, dimension( * ) BERR,
       real, dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SGBRFS

Purpose:
   SGBRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is banded, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
```

```
  The original band matrix A, stored in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is REAL array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by SGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from SGBTRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGBTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
```

```
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is REAL array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is REAL array, dimension (3*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbrfsx (TRANS, EQUED, N, KL, KU, NRHS, AB, LDAB, AFB,
           LDAFB, IPIV, R, C, B, LDB, X, LDX, RCOND, BERR, N_ERR_BNDS,
           ERR_BNDS_NORM, ERR_BNDS_COMP, NPARAMS, PARAMS, WORK, IWORK, INFO)
           SGBRFSX

Function/Subroutine Documentation
   subroutine sgbrfsx (character TRANS, character EQUED, integer N, integer
       KL, integer KU, integer NRHS, real, dimension( ldab, * ) AB, integer
       LDAB, real, dimension( ldafb, * ) AFB, integer LDAFB, integer,
       dimension( * ) IPIV, real, dimension( * ) R, real, dimension( * ) C,
       real, dimension( ldb, * ) B, integer LDB, real, dimension( ldx , * ) X,
       integer LDX, real RCOND, real, dimension( * ) BERR, integer N_ERR_BNDS,
       real, dimension( nrhs, * ) ERR_BNDS_NORM, real, dimension( nrhs, * )
       ERR_BNDS_COMP, integer NPARAMS, real, dimension( * ) PARAMS, real,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SGBRFSX

Purpose:
   SGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
```

```
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 AB
   AB is DOUBLE PRECISION array, dimension (LDAB,N)
```

```
  The original band matrix A, stored in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is DOUBLE PRECISION array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from SGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
```

```
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:
```

```
  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ----------------------------
                   max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
```

```
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)
```

```
  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
     componentwise error is not requested (PARAMS(3) = 0.0) then
     the Jth right-hand side is the first with a normwise error
     bound that is not guaranteed (the smallest J such
     that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
     the Jth right-hand side is the first with either a normwise or
     componentwise error bound that is not guaranteed (the smallest
     J such that either ERR_BNDS_NORM(J,1) = 0.0 or
     ERR_BNDS_COMP(J,1) = 0.0). See the definition of
     ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
     about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbtf2 (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           SGBTF2 computes the LU factorization of a general band matrix using
           the unblocked version of the algorithm.

Function/Subroutine Documentation
   subroutine sgbtf2 (integer M, integer N, integer KL, integer KU, real,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       integer INFO)
       SGBTF2 computes the LU factorization of a general band matrix using the
       unblocked version of the algorithm.

Purpose:
   SGBTF2 computes an LU factorization of a real m-by-n band matrix A
   using partial pivoting with row interchanges.
```

```
  This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows KL+1 to
   2*KL+KU+1; rows 1 to KL of the array need not be set.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

   On exit, details of the factorization: U is stored as an
   upper triangular band matrix with KL+KU superdiagonals in
   rows 1 to KL+KU+1, and the multipliers used during the
   factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
   See below for further details.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
      has been completed, but the factor U is exactly
```

```
      singular, and division by zero will occur if it is used
      to solve a system of equations.

Further Details:

   The band storage scheme is illustrated by the following example, when
   M = N = 6, KL = 2, KU = 1:

        On entry:                       On exit:

            *    *    *    +    +    +       *    *    *   u14  u25  u36
            *    *    +    +    +    +       *    *   u13  u24  u35  u46
            *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
           a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
           a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
           a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U, because of fill-in resulting from the row interchanges.

SYNOPSIS
   Functions/Subroutines
       subroutine sgbtrf (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           SGBTRF

Function/Subroutine Documentation
   subroutine sgbtrf (integer M, integer N, integer KL, integer KU, real,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       integer INFO)
       SGBTRF

Purpose:
   SGBTRF computes an LU factorization of a real m-by-n band matrix A
   using partial pivoting with row interchanges.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows KL+1 to
   2*KL+KU+1; rows 1 to KL of the array need not be set.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)
```

```
  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
       has been completed, but the factor U is exactly
       singular, and division by zero will occur if it is used
       to solve a system of equations.

Further Details:

  The band storage scheme is illustrated by the following example, when
  M = N = 6, KL = 2, KU = 1:

       On entry:                       On exit:

           *    *    *    +    +    +       *    *    *   u14  u25  u36
           *    *    +    +    +    +       *    *   u13  u24  u35  u46
           *   a12  a23  a34  a45  a56       *   u12  u23  u34  u45  u56
          a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
          a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
          a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

  Array elements marked * are not used by the routine; elements marked
  + need not be set on entry, but are required by the routine to store
  elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgbtrs (TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB,
           INFO)
           SGBTRS

Function/Subroutine Documentation
   subroutine sgbtrs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, real, dimension( ldab, * ) AB, integer LDAB, integer,
       dimension( * ) IPIV, real, dimension( ldb, * ) B, integer LDB, integer
       INFO)
       SGBTRS

Purpose:
   SGBTRS solves a system of linear equations
      A * X = B  or  A**T * X = B
   with a general band matrix A using the LU factorization computed by SGBTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B  (No transpose)
   = 'T':  A**T* X = B  (Transpose)
   = 'C':  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
```

```
  of the matrix B.  NRHS >= 0.

AB
  AB is REAL array, dimension (LDAB,N)
  Details of the LU factorization of the band matrix A, as
  computed by SGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sggbak (JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV,
           INFO)
           SGGBAK

Function/Subroutine Documentation
   subroutine sggbak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, real, dimension( * ) LSCALE, real, dimension( * ) RSCALE,
       integer M, real, dimension( ldv, * ) V, integer LDV, integer INFO)
       SGGBAK

Purpose:
   SGGBAK forms the right or left eigenvectors of a real generalized
   eigenvalue problem A*x = lambda*B*x, by backward transformation on
   the computed eigenvectors of the balanced pair of matrices output by
   SGGBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N':  do nothing, return immediately;
   = 'P':  do backward transformation for permutation only;
   = 'S':  do backward transformation for scaling only;
   = 'B':  do backward transformations for both permutation and scaling.
   JOB must be the same as the argument JOB supplied to SGGBAL.

 SIDE
   SIDE is CHARACTER*1
```

```
  = 'R':  V contains right eigenvectors;
  = 'L':  V contains left eigenvectors.

N
  N is INTEGER
  The number of rows of the matrix V.  N >= 0.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  The integers ILO and IHI determined by SGGBAL.
  1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE
  LSCALE is REAL array, dimension (N)
  Details of the permutations and/or scaling factors applied
  to the left side of A and B, as returned by SGGBAL.

RSCALE
  RSCALE is REAL array, dimension (N)
  Details of the permutations and/or scaling factors applied
  to the right side of A and B, as returned by SGGBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is REAL array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by STGEVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the matrix V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sggbal (JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
           WORK, INFO)
           SGGBAL

Function/Subroutine Documentation
   subroutine sggbal (character JOB, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( ldb, * ) B, integer LDB, integer ILO,
       integer IHI, real, dimension( * ) LSCALE, real, dimension( * ) RSCALE,
       real, dimension( * ) WORK, integer INFO)
       SGGBAL
```

```
Purpose:
   SGGBAL balances a pair of general real matrices (A,B).  This
   involves, first, permuting A and B by similarity transformations to
   isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N
   elements on the diagonal; and second, applying a diagonal similarity
   transformation to rows and columns ILO to IHI to make the rows
   and columns as close in norm as possible. Both steps are optional.

   Balancing may reduce the 1-norm of the matrices, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors in the
   generalized eigenvalue problem A*x = lambda*B*x.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A and B:
   = 'N':  none:  simply set ILO = 1, IHI = N, LSCALE(I) = 1.0
           and RSCALE(I) = 1.0 for i = 1,...,N.
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the input matrix A.
   On exit,  A is overwritten by the balanced matrix.
   If JOB = 'N', A is not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is REAL array, dimension (LDB,N)
   On entry, the input matrix B.
   On exit,  B is overwritten by the balanced matrix.
   If JOB = 'N', B is not referenced.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1,N).

 ILO
   ILO is INTEGER
```

```
IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If P(j) is the index of the
  row interchanged with row j, and D(j)
  is the scaling factor applied to row j, then
  LSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

RSCALE
  RSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If P(j) is the index of the
  column interchanged with column j, and D(j)
  is the scaling factor applied to column j, then
  LSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

WORK
  WORK is REAL array, dimension (lwork)
  lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and
  at least 1 when JOB = 'N' or 'P'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
   Functions/Subroutines
       subroutine sla_gbamv (TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX,
           BETA, Y, INCY)
           SLA_GBAMV performs a matrix-vector operation to calculate error
           bounds.

Function/Subroutine Documentation
   subroutine sla_gbamv (integer TRANS, integer M, integer N, integer KL,
       integer KU, real ALPHA, real, dimension( ldab, * ) AB, integer LDAB,
       real, dimension( * ) X, integer INCX, real BETA, real, dimension( * )
       Y, integer INCY)
       SLA_GBAMV performs a matrix-vector operation to calculate error bounds.

Purpose:
   SLA_GBAMV  performs one of the matrix-vector operations

        y := alpha*abs(A)*abs(x) + beta*abs(y),
   or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
```

```
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
   Unchanged on exit.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.
   Unchanged on exit.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.
   Unchanged on exit.

 AB
   AB is REAL array of DIMENSION ( LDAB, n )
   Before entry, the leading m by n part of the array AB must
   contain the matrix of coefficients.
   Unchanged on exit.
```

```
LDAB
  LDAB is INTEGER
  On entry, LDA specifies the first dimension of AB as declared
  in the calling (sub) program. LDAB must be at least
  max( 1, m ).
  Unchanged on exit.

X
  X is REAL array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the
  vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is REAL array, dimension
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.

SYNOPSIS
   Functions/Subroutines
       real function sla_gbrcond (TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB,
           IPIV, CMODE, C, INFO, WORK, IWORK)
           SLA_GBRCOND estimates the Skeel condition number for a general
           banded matrix.

Function/Subroutine Documentation
   real function sla_gbrcond (character TRANS, integer N, integer KL, integer
       KU, real, dimension( ldab, * ) AB, integer LDAB, real, dimension(
       ldafb, * ) AFB, integer LDAFB, integer, dimension( * ) IPIV, integer
       CMODE, real, dimension( * ) C, integer INFO, real, dimension( * ) WORK,
       integer, dimension( * ) IWORK)
       SLA_GBRCOND estimates the Skeel condition number for a general banded
       matrix.
```

```
Purpose:
   SLA_GBRCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= KL+KU+1.

 AFB
   AFB is REAL array, dimension (LDAFB,N)
   Details of the LU factorization of the band matrix A, as
   computed by SGBTRF.  U is stored as an upper triangular
   band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
   and the multipliers used during the factorization are stored
   in rows KL+KU+2 to 2*KL+KU+1.
```

```
LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by SGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is REAL array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is REAL array, dimension (5*N).
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.

       SLA_GBRFSX_EXTENDED improves the computed solution to a system of
       linear equations for general banded matrices by performing extra-
       precise iterative refinement and provides error bounds and backward
       error estimates for the solution.

Purpose:
   SLA_GBRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by SGBRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
```

```
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 TRANS_TYPE
   TRANS_TYPE is INTEGER
   Specifies the transposition operation on A.
   The value is defined by ILATRANS(T) where T is a CHARACTER and
   T    = 'N':  No transpose
        = 'T':  Transpose
        = 'C':  Conjugate transpose

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.

 AB
   AB is REAL array, dimension (LDAB,N)
   On entry, the N-by-N matrix AB.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= max(1,N).

 AFB
   AFB is REAL array, dimension (LDAFB,N)
```

```
  The factors L and U from the factorization
  A = P*L*U as computed by SGBTRF.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AF.  LDAFB >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by SGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is REAL array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by SGBTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
```

```
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.
```

```
  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
```

```
  RES is REAL array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is REAL array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.

DY
  DY is REAL array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is REAL array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
```

```
  more details.

 IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

 INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to SGBTRS had an illegal value
```

sla_gbrpvgrw examples
=====================================================================

=====================================================================
Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       real function sla_gbrpvgrw (N, KL, KU, NCOLS, AB, LDAB, AFB, LDAFB)
           SLA_GBRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a general banded matrix.

Function/Subroutine Documentation
   real function sla_gbrpvgrw (integer N, integer KL, integer KU, integer
       NCOLS, real, dimension( ldab, * ) AB, integer LDAB, real, dimension(
       ldafb, * ) AFB, integer LDAFB)
       SLA_GBRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a general banded matrix.

Purpose:
   SLA_GBRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
```

```
  matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NCOLS
  NCOLS is INTEGER
  The number of columns of the matrix A.  NCOLS >= 0.

AB
  AB is REAL array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is REAL array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by SGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

SYNOPSIS
   Functions/Subroutines
       subroutine sorgbr (VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
           SORGBR

Function/Subroutine Documentation
   subroutine sorgbr (character VECT, integer M, integer N, integer K, real,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) TAU, real,
       dimension( * ) WORK, integer LWORK, integer INFO)
       SORGBR

Purpose:
   SORGBR generates one of the real orthogonal matrices Q or P**T
   determined by SGEBRD when reducing a real matrix A to bidiagonal
   form: A = Q * B * P**T.  Q and P**T are defined as products of
   elementary reflectors H(i) or G(i) respectively.

   If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q
   is of order M:
   if m >= k, Q = H(1) H(2) . . . H(k) and SORGBR returns the first n
   columns of Q, where m >= n >= k;
   if m < k, Q = H(1) H(2) . . . H(m-1) and SORGBR returns Q as an
   M-by-M matrix.

   If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**T
   is of order N:
   if k < n, P**T = G(k) . . . G(2) G(1) and SORGBR returns the first m
   rows of P**T, where n >= m >= k;
```

```
   if k >= n, P**T = G(n-1) . . . G(2) G(1) and SORGBR returns P**T as
   an N-by-N matrix.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether the matrix Q or the matrix P**T is
   required, as defined in the transformation applied by SGEBRD:
   = 'Q':  generate Q;
   = 'P':  generate P**T.

 M
   M is INTEGER
   The number of rows of the matrix Q or P**T to be returned.
   M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix Q or P**T to be returned.
   N >= 0.
   If VECT = 'Q', M >= N >= min(M,K);
   if VECT = 'P', N >= M >= min(N,K).

 K
   K is INTEGER
   If VECT = 'Q', the number of columns in the original M-by-K
   matrix reduced by SGEBRD.
   If VECT = 'P', the number of rows in the original K-by-N
   matrix reduced by SGEBRD.
   K >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the vectors which define the elementary reflectors,
   as returned by SGEBRD.
   On exit, the M-by-N matrix Q or P**T.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,M).

 TAU
   TAU is REAL array, dimension
      (min(M,K)) if VECT = 'Q'
      (min(N,K)) if VECT = 'P'
   TAU(i) must contain the scalar factor of the elementary
   reflector H(i) or G(i), which determines Q or P**T, as
   returned by SGEBRD in its array argument TAUQ or TAUP.
```

```
 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK >= max(1,min(M,N)).
   For optimum performance LWORK >= min(M,N)*NB, where NB
   is the optimal blocksize.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbbrd (VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT,
           LDPT, C, LDC, WORK, RWORK, INFO)
           CGBBRD

Function/Subroutine Documentation
   subroutine cgbbrd (character VECT, integer M, integer N, integer NCC,
       integer KL, integer KU, complex, dimension( ldab, * ) AB, integer LDAB,
       real, dimension( * ) D, real, dimension( * ) E, complex, dimension(
       ldq, * ) Q, integer LDQ, complex, dimension( ldpt, * ) PT, integer
       LDPT, complex, dimension( ldc, * ) C, integer LDC, complex, dimension(
       * ) WORK, real, dimension( * ) RWORK, integer INFO)
       CGBBRD

Purpose:
   CGBBRD reduces a complex general m-by-n band matrix A to real upper
   bidiagonal form B by a unitary transformation: Q**H * A * P = B.

   The routine computes B, and optionally forms Q or P**H, or computes
   Q**H*C for a given matrix C.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether or not the matrices Q and P**H are to be
   formed.
   = 'N': do not form Q or P**H;
   = 'Q': form Q only;
   = 'P': form P**H only;
   = 'B': form both.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NCC
   NCC is INTEGER
```

```
  The number of columns of the matrix C.  NCC >= 0.

KL
  KL is INTEGER
  The number of subdiagonals of the matrix A. KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals of the matrix A. KU >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the m-by-n band matrix A, stored in rows 1 to
  KL+KU+1. The j-th column of A is stored in the j-th column of
  the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).
  On exit, A is overwritten by values generated during the reduction.

LDAB
  LDAB is INTEGER
  The leading dimension of the array A. LDAB >= KL+KU+1.

D
  D is REAL array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B.

E
  E is REAL array, dimension (min(M,N)-1)
  The superdiagonal elements of the bidiagonal matrix B.

Q
  Q is COMPLEX array, dimension (LDQ,M)
  If VECT = 'Q' or 'B', the m-by-m unitary matrix Q.
  If VECT = 'N' or 'P', the array Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.
  LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT
  PT is COMPLEX array, dimension (LDPT,N)
  If VECT = 'P' or 'B', the n-by-n unitary matrix P'.
  If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT
  LDPT is INTEGER
  The leading dimension of the array PT.
  LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.
```

```
C
  C is COMPLEX array, dimension (LDC,NCC)
  On entry, an m-by-ncc matrix C.
  On exit, C is overwritten by Q**H*C.
  C is not referenced if NCC = 0.

LDC
  LDC is INTEGER
  The leading dimension of the array C.
  LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK
  WORK is COMPLEX array, dimension (max(M,N))

RWORK
  RWORK is REAL array, dimension (max(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbcon (NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK,
           RWORK, INFO)
           CGBCON

Function/Subroutine Documentation
   subroutine cgbcon (character NORM, integer N, integer KL, integer KU,
       complex, dimension( ldab, * ) AB, integer LDAB, integer, dimension( * )
       IPIV, real ANORM, real RCOND, complex, dimension( * ) WORK, real,
       dimension( * ) RWORK, integer INFO)
       CGBCON

Purpose:
   CGBCON estimates the reciprocal of the condition number of a complex
   general band matrix A, in either the 1-norm or the infinity-norm,
   using the LU factorization computed by CGBTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
      RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
```

```
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  Details of the LU factorization of the band matrix A, as
  computed by CGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

ANORM
  ANORM is REAL
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is REAL
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cgbequ (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           CGBEQU

Function/Subroutine Documentation
   subroutine cgbequ (integer M, integer N, integer KL, integer KU, complex,
       dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) R, real,
       dimension( * ) C, real ROWCND, real COLCND, real AMAX, integer INFO)
       CGBEQU

Purpose:
   CGBEQU computes row and column scalings intended to equilibrate an
   M-by-N band matrix A and reduce its condition number.  R returns the
   row scale factors and C the column scale factors, chosen to try to
```

```
  make the largest element in each row and column of the matrix B with
  elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

  R(i) and C(j) are restricted to be between SMLNUM = smallest safe
  number and BIGNUM = largest safe number.  Use of these scaling
  factors is not guaranteed to reduce the condition number of A but
  works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
   The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
   column of A is stored in the j-th column of the array AB as follows:
        AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= KL+KU+1.

 R
   R is REAL array, dimension (M)
   If INFO = 0, or INFO > M, R contains the row scale factors for A.

 C
   C is REAL array, dimension (N)
   If INFO = 0, C contains the column scale factors for A.

 ROWCND
   ROWCND is REAL
   If INFO = 0 or INFO > M, ROWCND contains the ratio of the
   smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
   AMAX is neither too large nor too small, it is not worth
   scaling by R.
```

```
COLCND
  COLCND is REAL
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not
  worth scaling by C.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
        <= M:  the i-th row of A is exactly zero
        >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbequb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           CGBEQUB

Function/Subroutine Documentation
   subroutine cgbequb (integer M, integer N, integer KL, integer KU, complex,
       dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) R, real,
       dimension( * ) C, real ROWCND, real COLCND, real AMAX, integer INFO)
       CGBEQUB

Purpose:

   CGBEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from CGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.
```

```
N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array A.  LDAB >= max(1,M).

R
  R is REAL array, dimension (M)
  If INFO = 0 or INFO > M, R contains the row scale factors for A.

C
  C is REAL array, dimension (N)
  If INFO = 0,  C contains the column scale factors for A.

ROWCND
  ROWCND is REAL
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth
  scaling by R.

COLCND
  COLCND is REAL
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not
  worth scaling by C.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i,  and i is
         <= M:  the i-th row of A is exactly zero
         >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbrfs (TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, RWORK, INFO)
           CGBRFS

Function/Subroutine Documentation
   subroutine cgbrfs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, complex, dimension( ldab, * ) AB, integer LDAB, complex,
       dimension( ldafb, * ) AFB, integer LDAFB, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, complex, dimension( ldx, *
       ) X, integer LDX, real, dimension( * ) FERR, real, dimension( * ) BERR,
       complex, dimension( * ) WORK, real, dimension( * ) RWORK, integer INFO)
       CGBRFS

Purpose:
```

```
  CGBRFS improves the computed solution to a system of linear
  equations when the coefficient matrix is banded, and provides
  error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
   The original band matrix A, stored in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= KL+KU+1.

 AFB
   AFB is COMPLEX array, dimension (LDAFB,N)
   Details of the LU factorization of the band matrix A, as
   computed by CGBTRF.  U is stored as an upper triangular band
   matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
   the multipliers used during the factorization are stored in
   rows KL+KU+2 to 2*KL+KU+1.

 LDAFB
```

```
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from CGBTRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CGBTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
```

```
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.
```

       complex, dimension( * ) WORK, real, dimension( * ) RWORK, integer INFO)
       CGBRFSX

Purpose:
   CGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.
```

```
   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).
   The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
   The original band matrix A, stored in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
```

```
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from SGETRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

R
  R is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is REAL array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
```

```
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
        max_j (abs(XTRUE(j,i) - X(j,i)))
```

```
     -----------------------------
           max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
          reciprocal condition number.  Compared with the threshold
          sqrt(n) * slamch('Epsilon') to determine if the error
          estimate is "guaranteed". These reciprocal condition
          numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
          appropriately scaled matrix Z.
          Let Z = S*A, where S scales each row by a power of the
          radix so all absolute row sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

ERR_BNDS_COMP

  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
              abs(XTRUE(j,i) - X(j,i))
      max_j ----------------------
                   abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
```

```
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
          reciprocal condition number.  Compared with the threshold
          sqrt(n) * slamch('Epsilon') to determine if the error
          estimate is "guaranteed". These reciprocal condition
          numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
          appropriately scaled matrix Z.
          Let Z = S*(A*diag(x)), where x is the solution for the
          current right-hand side and S scales each row of
          A*diag(x) by a power of the radix so all absolute row
          sums of Z are approximately 1.

  See Lapack Working Note 165 for further details and extra cautions.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.

  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
```

```
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
          (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.

  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.

  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
        guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
        has been completed, but the factor U is exactly singular, so
        the solution and error bounds could not be computed. RCOND = 0
        is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
          not guaranteed. The solutions corresponding to other right-
          hand sides K with K > J may not be guaranteed as well, but
          only the first such right-hand side is reported. If a small
          componentwise error is not requested (PARAMS(3) = 0.0) then
          the Jth right-hand side is the first with a normwise error
          bound that is not guaranteed (the smallest J such
          that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
          the Jth right-hand side is the first with either a normwise or
          componentwise error bound that is not guaranteed (the smallest
          J such that either ERR_BNDS_NORM(J,1) = 0.0 or
          ERR_BNDS_COMP(J,1) = 0.0). See the definition of
          ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
          about all of the right-hand sides check ERR_BNDS_NORM or

SYNOPSIS
   Functions/Subroutines
       subroutine cgbtf2 (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           CGBTF2 computes the LU factorization of a general band matrix using
           the unblocked version of the algorithm.

Function/Subroutine Documentation
   subroutine cgbtf2 (integer M, integer N, integer KL, integer KU, complex,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       integer INFO)
       CGBTF2 computes the LU factorization of a general band matrix using the
       unblocked version of the algorithm.
```

```
Purpose:
   CGBTF2 computes an LU factorization of a complex m-by-n band matrix
   A using partial pivoting with row interchanges.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows KL+1 to
   2*KL+KU+1; rows 1 to KL of the array need not be set.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

   On exit, details of the factorization: U is stored as an
   upper triangular band matrix with KL+KU superdiagonals in
   rows 1 to KL+KU+1, and the multipliers used during the
   factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
   See below for further details.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
   IPIV is INTEGER array, dimension (min(M,N))
   The pivot indices; for 1 <= i <= min(M,N), row i of the
   matrix was interchanged with row IPIV(i).

 INFO
   INFO is INTEGER
```

```
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
        has been completed, but the factor U is exactly
        singular, and division by zero will occur if it is used
        to solve a system of equations.

 The band storage scheme is illustrated by the following example, when
 M = N = 6, KL = 2, KU = 1:

    On entry:                       On exit:

        *    *    *    +    +    +       *    *    *   u14  u25  u36
        *    *    +    +    +    +       *    *   u13  u24  u35  u46
        *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
       a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
       a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
       a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U, because of fill-in resulting from the row
   interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbtrf (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           CGBTRF

Function/Subroutine Documentation
   subroutine cgbtrf (integer M, integer N, integer KL, integer KU, complex,
       dimension( ldab, * ) AB, integer LDAB, integer, dimension( * ) IPIV,
       integer INFO)
       CGBTRF

Purpose:
   CGBTRF computes an LU factorization of a complex m-by-n band matrix A
   using partial pivoting with row interchanges.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
```

```
  On entry, the matrix A in band storage, in rows KL+1 to
  2*KL+KU+1; rows 1 to KL of the array need not be set.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
       has been completed, but the factor U is exactly
       singular, and division by zero will occur if it is used
       to solve a system of equations.

The band storage scheme is illustrated by the following example, when
M = N = 6, KL = 2, KU = 1:

  On entry:                       On exit:

  *    *    *    +    +    +       *    *    *   u14  u25  u36
  *    *    +    +    +    +       *    *   u13  u24  u35  u46
  *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
  a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
  a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
  a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

  Array elements marked * are not used by the routine; elements marked
  + need not be set on entry, but are required by the routine to store
  elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbtrs (TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB,
           INFO)
           CGBTRS

Function/Subroutine Documentation
   subroutine cgbtrs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, complex, dimension( ldab, * ) AB, integer LDAB, integer,
       dimension( * ) IPIV, complex, dimension( ldb, * ) B, integer LDB,
       integer INFO)
       CGBTRS

Purpose:
   CGBTRS solves a system of linear equations
      A * X = B,  A**T * X = B,  or  A**H * X = B
   with a general band matrix A using the LU factorization computed
   by CGBTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
```

```
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  Details of the LU factorization of the band matrix A, as
  computed by CGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

       integer IHI, real, dimension( * ) LSCALE, real, dimension( * ) RSCALE,
       integer M, complex, dimension( ldv, * ) V, integer LDV, integer INFO)
       CGGBAK

Purpose:
   CGGBAK forms the right or left eigenvectors of a complex generalized
   eigenvalue problem A*x = lambda*B*x, by backward transformation on
   the computed eigenvectors of the balanced pair of matrices output by
   CGGBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N':  do nothing, return immediately;
   = 'P':  do backward transformation for permutation only;
   = 'S':  do backward transformation for scaling only;
   = 'B':  do backward transformations for both permutation and
           scaling.
   JOB must be the same as the argument JOB supplied to CGGBAL.

 SIDE
   SIDE is CHARACTER*1
   = 'R':  V contains right eigenvectors;
   = 'L':  V contains left eigenvectors.

 N
   N is INTEGER
   The number of rows of the matrix V.  N >= 0.

 ILO
   ILO is INTEGER

 IHI
   IHI is INTEGER
   The integers ILO and IHI determined by CGGBAL.
   1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

 LSCALE
   LSCALE is REAL array, dimension (N)
   Details of the permutations and/or scaling factors applied
   to the left side of A and B, as returned by CGGBAL.

 RSCALE
```

```
  RSCALE is REAL array, dimension (N)
  Details of the permutations and/or scaling factors applied
  to the right side of A and B, as returned by CGGBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is COMPLEX array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by CTGEVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the matrix V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cggbal (JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
           WORK, INFO)
           CGGBAL

Function/Subroutine Documentation
   subroutine cggbal (character JOB, integer N, complex, dimension( lda, * )
       A, integer LDA, complex, dimension( ldb, * ) B, integer LDB, integer
       ILO, integer IHI, real, dimension( * ) LSCALE, real, dimension( * )
       RSCALE, real, dimension( * ) WORK, integer INFO)
       CGGBAL

Purpose:
   CGGBAL balances a pair of general complex matrices (A,B).  This
   involves, first, permuting A and B by similarity transformations to
   isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N
   elements on the diagonal; and second, applying a diagonal similarity
   transformation to rows and columns ILO to IHI to make the rows
   and columns as close in norm as possible. Both steps are optional.

   Balancing may reduce the 1-norm of the matrices, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors in the
   generalized eigenvalue problem A*x = lambda*B*x.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A and B:
```

```
  = 'N':  none:  simply set ILO = 1, IHI = N, LSCALE(I) = 1.0
          and RSCALE(I) = 1.0 for i=1,...,N;
  = 'P':  permute only;
  = 'S':  scale only;
  = 'B':  both permute and scale.

N
  N is INTEGER
  The order of the matrices A and B.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the input matrix A.
  On exit, A is overwritten by the balanced matrix.
  If JOB = 'N', A is not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,N).

B
  B is COMPLEX array, dimension (LDB,N)
  On entry, the input matrix B.
  On exit, B is overwritten by the balanced matrix.
  If JOB = 'N', B is not referenced.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If P(j) is the index of the
  row interchanged with row j, and D(j) is the scaling factor
  applied to row j, then
  LSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
```

```
  then 1 to ILO-1.

RSCALE
  RSCALE is REAL array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If P(j) is the index of the
  column interchanged with column j, and D(j) is the scaling
  factor applied to column j, then
  RSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

WORK
  WORK is REAL array, dimension (lwork)
  lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and
  at least 1 when JOB = 'N' or 'P'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cla_gbamv (TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX,
           BETA, Y, INCY)
           CLA_GBAMV performs a matrix-vector operation to calculate error
           bounds.

Function/Subroutine Documentation
   subroutine cla_gbamv (integer TRANS, integer M, integer N, integer KL,
       integer KU, real ALPHA, complex, dimension( ldab, * ) AB, integer LDAB,
       complex, dimension( * ) X, integer INCX, real BETA, real, dimension( *
       ) Y, integer INCY)
       CLA_GBAMV performs a matrix-vector operation to calculate error bounds.

Purpose:
   CLA_GBAMV  performs one of the matrix-vector operations

               y := alpha*abs(A)*abs(x) + beta*abs(y),
         or    y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
```

```
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
   M is INTEGER
   On entry, M specifies the number of rows of the matrix A.
   M must be at least zero.
   Unchanged on exit.

 N
   N is INTEGER
   On entry, N specifies the number of columns of the matrix A.
   N must be at least zero.
   Unchanged on exit.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 ALPHA
   ALPHA is REAL
   On entry, ALPHA specifies the scalar alpha.
   Unchanged on exit.

 AB
   AB is REAL array, dimension (LDAB,n)
   Before entry, the leading m by n part of the array AB must
   contain the matrix of coefficients.
   Unchanged on exit.
```

```
LDAB
  LDAB is INTEGER
  On entry, LDAB specifies the first dimension of AB as declared
  in the calling (sub) program. LDAB must be at least
  max( 1, m ).
  Unchanged on exit.

X
  X is REAL array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the
  vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is REAL
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is REAL array, dimension
  ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.

SYNOPSIS
   Functions/Subroutines
       real function cla_gbrcond_c (TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB,
           IPIV, C, CAPPLY, INFO, WORK, RWORK)
           CLA_GBRCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for general banded matrices.

Function/Subroutine Documentation
   real function cla_gbrcond_c (character TRANS, integer N, integer KL,
       integer KU, complex, dimension( ldab, * ) AB, integer LDAB, complex,
       dimension( ldafb, * ) AFB, integer LDAFB, integer, dimension( * ) IPIV,
       real, dimension( * ) C, logical CAPPLY, integer INFO, complex,
       dimension( * ) WORK, real, dimension( * ) RWORK)
       CLA_GBRCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for general banded matrices.

Purpose:
   CLA_GBRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)
```

```
N
  N is INTEGER
  The number of linear equations, i.e., the order of the
  matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by CGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by CGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

C
  C is REAL array, dimension (N)
  The vector C in the formula op(A) * inv(diag(C)).

CAPPLY
  CAPPLY is LOGICAL
  If .TRUE. then access the vector C in the formula above.
```

```
 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
   WORK is COMPLEX array, dimension (2*N).
   Workspace.

 RWORK
   RWORK is REAL array, dimension (N).
   Workspace.
```

SYNOPSIS
   Functions/Subroutines
       real function cla_gbrcond_x (TRANS, N, KL, KU, AB, LDAB, AFB, LDAFB,
           IPIV, X, INFO, WORK, RWORK)
           CLA_GBRCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for general banded matrices.

Function/Subroutine Documentation
```

```
   real function cla_gbrcond_x (character TRANS, integer N, integer KL,
       integer KU, complex, dimension( ldab, * ) AB, integer LDAB, complex,
       dimension( ldafb, * ) AFB, integer LDAFB, integer, dimension( * ) IPIV,
       complex, dimension( * ) X, integer INFO, complex, dimension( * ) WORK,
       real, dimension( * ) RWORK)
       CLA_GBRCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for general banded matrices.

Purpose:
   CLA_GBRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= KL+KU+1.

 AFB
   AFB is COMPLEX array, dimension (LDAFB,N)
   Details of the LU factorization of the band matrix A, as
   computed by CGBTRF.  U is stored as an upper triangular
   band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
```

```
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by CGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

X
  X is COMPLEX array, dimension (N)
  The vector X in the formula op(A) * diag(X).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX array, dimension (2*N).
  Workspace.

RWORK
  RWORK is REAL array, dimension (N).
  Workspace.
```

      CLA_GBRFSX_EXTENDED improves the computed solution to a system of
      linear equations for general banded matrices by performing extra-
      precise iterative refinement and provides error bounds and backward
      error estimates for the solution.

Purpose:
   CLA_GBRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by CGBRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 TRANS_TYPE
   TRANS_TYPE is INTEGER
   Specifies the transposition operation on A.
   The value is defined by ILATRANS(T) where T is a CHARACTER and
   T    = 'N':  No transpose
        = 'T':  Transpose
        = 'C':  Conjugate transpose

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.
```

```
KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the N-by-N matrix AB.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= max(1,N).

AFB
  AFB is COMPLEX array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by CGBTRF.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by CGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
```

```
  B is COMPLEX array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by CGBTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
           ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
```

```
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*A, where S scales each row by a power of the
           radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
          reciprocal condition number is less than the threshold
          sqrt(n) * slamch('Epsilon').
```

```
  err = 2 "Guaranteed" error bound: The estimated forward error,
          almost certainly within a factor of 10 of the true error
          so long as the next entry is greater than the threshold
          sqrt(n) * slamch('Epsilon'). This error bound should only
          be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
           reciprocal condition number.  Compared with the threshold
           sqrt(n) * slamch('Epsilon') to determine if the error
           estimate is "guaranteed". These reciprocal condition
           numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
           appropriately scaled matrix Z.
           Let Z = S*(A*diag(x)), where x is the solution for the
           current right-hand side and S scales each row of
           A*diag(x) by a power of the radix so all absolute row
           sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is REAL array, dimension (N)
  Workspace.

DY
  DY is COMPLEX array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
```

```
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to CGBTRS had an illegal value

cla_gbrpvgrw examples
=====================================================================

=====================================================================
Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       real function cla_gbrpvgrw (N, KL, KU, NCOLS, AB, LDAB, AFB, LDAFB)
           CLA_GBRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a general banded matrix.

Function/Subroutine Documentation
   real function cla_gbrpvgrw (integer N, integer KL, integer KU, integer
       NCOLS, complex, dimension( ldab, * ) AB, integer LDAB, complex,
       dimension( ldafb, * ) AFB, integer LDAFB)
       CLA_GBRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a general banded matrix.

Purpose:
   CLA_GBRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
```

```
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NCOLS
  NCOLS is INTEGER
  The number of columns of the matrix A.  NCOLS >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by CGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

SYNOPSIS
   Functions/Subroutines
       subroutine cungbr (VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
           CUNGBR

Function/Subroutine Documentation
   subroutine cungbr (character VECT, integer M, integer N, integer K,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( * )
       TAU, complex, dimension( * ) WORK, integer LWORK, integer INFO)
       CUNGBR

Purpose:
   CUNGBR generates one of the complex unitary matrices Q or P**H
   determined by CGEBRD when reducing a complex matrix A to bidiagonal
   form: A = Q * B * P**H.  Q and P**H are defined as products of
   elementary reflectors H(i) or G(i) respectively.
```

```
  If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q
  is of order M:
  if m >= k, Q = H(1) H(2) . . . H(k) and CUNGBR returns the first n
  columns of Q, where m >= n >= k;
  if m < k, Q = H(1) H(2) . . . H(m-1) and CUNGBR returns Q as an
  M-by-M matrix.

  If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**H
  is of order N:
  if k < n, P**H = G(k) . . . G(2) G(1) and CUNGBR returns the first m
  rows of P**H, where n >= m >= k;
  if k >= n, P**H = G(n-1) . . . G(2) G(1) and CUNGBR returns P**H as
  an N-by-N matrix.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether the matrix Q or the matrix P**H is
   required, as defined in the transformation applied by CGEBRD:
   = 'Q':  generate Q;
   = 'P':  generate P**H.

 M
   M is INTEGER
   The number of rows of the matrix Q or P**H to be returned.
   M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix Q or P**H to be returned.
   N >= 0.
   If VECT = 'Q', M >= N >= min(M,K);
   if VECT = 'P', N >= M >= min(N,K).

 K
   K is INTEGER
   If VECT = 'Q', the number of columns in the original M-by-K
   matrix reduced by CGEBRD.
   If VECT = 'P', the number of rows in the original K-by-N
   matrix reduced by CGEBRD.
   K >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the vectors which define the elementary reflectors,
   as returned by CGEBRD.
   On exit, the M-by-N matrix Q or P**H.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= M.

TAU
  TAU is COMPLEX array, dimension
     (min(M,K)) if VECT = 'Q'
     (min(N,K)) if VECT = 'P'
  TAU(i) must contain the scalar factor of the elementary
  reflector H(i) or G(i), which determines Q or P**H, as
  returned by CGEBRD in its array argument TAUQ or TAUP.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= max(1,min(M,N)).
  For optimum performance LWORK >= min(M,N)*NB, where NB
  is the optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbbrd (VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT,
           LDPT, C, LDC, WORK, RWORK, INFO)
           ZGBBRD

Function/Subroutine Documentation
   subroutine zgbbrd (character VECT, integer M, integer N, integer NCC,
       integer KL, integer KU, complex*16, dimension( ldab, * ) AB, integer
       LDAB, double precision, dimension( * ) D, double precision, dimension(
       * ) E, complex*16, dimension( ldq, * ) Q, integer LDQ, complex*16,
       dimension( ldpt, * ) PT, integer LDPT, complex*16, dimension( ldc, * )
       C, integer LDC, complex*16, dimension( * ) WORK, double precision,
       dimension( * ) RWORK, integer INFO)
       ZGBBRD

Purpose:
   ZGBBRD reduces a complex general m-by-n band matrix A to real upper
   bidiagonal form B by a unitary transformation: Q**H * A * P = B.

   The routine computes B, and optionally forms Q or P**H, or computes
   Q**H*C for a given matrix C.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether or not the matrices Q and P**H are to be
   formed.
   = 'N': do not form Q or P**H;
   = 'Q': form Q only;
   = 'P': form P**H only;
   = 'B': form both.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 NCC
```

```
  NCC is INTEGER
  The number of columns of the matrix C.  NCC >= 0.

KL
  KL is INTEGER
  The number of subdiagonals of the matrix A. KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals of the matrix A. KU >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  On entry, the m-by-n band matrix A, stored in rows 1 to
  KL+KU+1. The j-th column of A is stored in the j-th column of
  the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).
  On exit, A is overwritten by values generated during the
  reduction.

LDAB
  LDAB is INTEGER
  The leading dimension of the array A. LDAB >= KL+KU+1.

D
  D is DOUBLE PRECISION array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B.

E
  E is DOUBLE PRECISION array, dimension (min(M,N)-1)
  The superdiagonal elements of the bidiagonal matrix B.

Q
  Q is COMPLEX*16 array, dimension (LDQ,M)
  If VECT = 'Q' or 'B', the m-by-m unitary matrix Q.
  If VECT = 'N' or 'P', the array Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.
  LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT
  PT is COMPLEX*16 array, dimension (LDPT,N)
  If VECT = 'P' or 'B', the n-by-n unitary matrix P'.
  If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT
  LDPT is INTEGER
  The leading dimension of the array PT.
```

```
  LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C
  C is COMPLEX*16 array, dimension (LDC,NCC)
  On entry, an m-by-ncc matrix C.
  On exit, C is overwritten by Q**H*C.
  C is not referenced if NCC = 0.

LDC
  LDC is INTEGER
  The leading dimension of the array C.
  LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK
  WORK is COMPLEX*16 array, dimension (max(M,N))

RWORK
  RWORK is DOUBLE PRECISION array, dimension (max(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbcon (NORM, N, KL, KU, AB, LDAB, IPIV, ANORM, RCOND, WORK,
           RWORK, INFO)
           ZGBCON

Function/Subroutine Documentation
```

```
   subroutine zgbcon (character NORM, integer N, integer KL, integer KU,
       complex*16, dimension( ldab, * ) AB, integer LDAB, integer, dimension(
       * ) IPIV, double precision ANORM, double precision RCOND, complex*16,
       dimension( * ) WORK, double precision, dimension( * ) RWORK, integer
       INFO)
       ZGBCON

Purpose:
   ZGBCON estimates the reciprocal of the condition number of a complex
   general band matrix A, in either the 1-norm or the infinity-norm,
   using the LU factorization computed by ZGBTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   Details of the LU factorization of the band matrix A, as
   computed by ZGBTRF.  U is stored as an upper triangular band
   matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
   the multipliers used during the factorization are stored in
   rows KL+KU+2 to 2*KL+KU+1.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
```

```
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= N, row i of the matrix was
  interchanged with row IPIV(i).

ANORM
  ANORM is DOUBLE PRECISION
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbequ (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           ZGBEQU

Function/Subroutine Documentation
   subroutine zgbequ (integer M, integer N, integer KL, integer KU,
       complex*16, dimension( ldab, * ) AB, integer LDAB, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision
       ROWCND, double precision COLCND, double precision AMAX, integer INFO)
       ZGBEQU

Purpose:
   ZGBEQU computes row and column scalings intended to equilibrate an
   M-by-N band matrix A and reduce its condition number.  R returns the
   row scale factors and C the column scale factors, chosen to try to
   make the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

   R(i) and C(j) are restricted to be between SMLNUM = smallest safe
   number and BIGNUM = largest safe number.  Use of these scaling
   factors is not guaranteed to reduce the condition number of A but
   works well in practice.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.
```

```
AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
  column of A is stored in the j-th column of the array AB as
  follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

R
  R is DOUBLE PRECISION array, dimension (M)
  If INFO = 0, or INFO > M, R contains the row scale factors for A.

C
  C is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, C contains the column scale factors for A.

ROWCND
  ROWCND is DOUBLE PRECISION
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is DOUBLE PRECISION
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
    <= M:  the i-th row of A is exactly zero
    >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbequb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           INFO)
           ZGBEQUB

Function/Subroutine Documentation
   subroutine zgbequb (integer M, integer N, integer KL, integer KU,
       complex*16, dimension( ldab, * ) AB, integer LDAB, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision
       ROWCND, double precision COLCND, double precision AMAX, integer INFO)
       ZGBEQUB
```

```
Purpose:
   ZGBEQUB computes row and column scalings intended to equilibrate an
   M-by-N matrix A and reduce its condition number.  R returns the row
   scale factors and C the column scale factors, chosen to try to make
   the largest element in each row and column of the matrix B with
   elements B(i,j)=R(i)*A(i,j)*C(j) have an absolute value of at most
   the radix.

   R(i) and C(j) are restricted to be a power of the radix between
   SMLNUM = smallest safe number and BIGNUM = largest safe number.  Use
   of these scaling factors is not guaranteed to reduce the condition
   number of A but works well in practice.

   This routine differs from ZGEEQU by restricting the scaling factors
   to a power of the radix.  Baring over- and underflow, scaling by
   these factors introduces no additional rounding errors.  However, the
   scaled entries' magnitured are no longer approximately 1 but lie
   between sqrt(radix) and 1/sqrt(radix).

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is DOUBLE PRECISION array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

 LDAB
   LDAB is INTEGER
   The leading dimension of the array A.  LDAB >= max(1,M).

 R
```

```
  R is DOUBLE PRECISION array, dimension (M)
  If INFO = 0 or INFO > M, R contains the row scale factors for A.

C
  C is DOUBLE PRECISION array, dimension (N)
  If INFO = 0,  C contains the column scale factors for A.

ROWCND
  ROWCND is DOUBLE PRECISION
  If INFO = 0 or INFO > M, ROWCND contains the ratio of the
  smallest R(i) to the largest R(i).  If ROWCND >= 0.1 and
  AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND
  COLCND is DOUBLE PRECISION
  If INFO = 0, COLCND contains the ratio of the smallest
  C(i) to the largest C(i).  If COLCND >= 0.1, it is not worth scaling by C.

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i,  and i is
     <= M:  the i-th row of A is exactly zero
     >  M:  the (i-M)-th column of A is exactly zero
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbrfs (TRANS, N, KL, KU, NRHS, AB, LDAB, AFB, LDAFB, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, RWORK, INFO)
           ZGBRFS

Function/Subroutine Documentation
   subroutine zgbrfs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, complex*16, dimension( ldab, * ) AB, integer LDAB,
       complex*16, dimension( ldafb, * ) AFB, integer LDAFB, integer,
       dimension( * ) IPIV, complex*16, dimension( ldb, * ) B, integer LDB,
       complex*16, dimension( ldx, * ) X, integer LDX, double precision,
       dimension( * ) FERR, double precision, dimension( * ) BERR, complex*16,
       dimension( * ) WORK, double precision, dimension( * ) RWORK, integer
       INFO)
       ZGBRFS

Purpose:
   ZGBRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is banded, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  The original band matrix A, stored in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX*16 array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by ZGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from ZGBTRF; for 1<=i<=N, row i of the
  matrix was interchanged with row IPIV(i).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZGBTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).
```

```
 FERR
   FERR is DOUBLE PRECISION array, dimension (NRHS)
   The estimated forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.
```

       WORK, double precision, dimension( * ) RWORK, integer INFO)
       ZGBRFSX

Purpose:
   ZGBRFSX improves the computed solution to a system of linear
   equations and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED, R
   and C below. In this case, the solution and error bounds returned
   are for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
```

```
  = 'N':  No equilibration
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).
          The right hand side B has been changed accordingly.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  The original band matrix A, stored in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX*16 array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by DGBTRF.  U is stored as an upper triangular band
  matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
  the multipliers used during the factorization are stored in
  rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL*KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from DGETRF; for 1<=i<=N, row i of the
```

```
  matrix was interchanged with row IPIV(i).

R
  R is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'R' or 'B', A is
  multiplied on the left by diag(R); if EQUED = 'N' or 'C', R
  is not accessed.  R is an input argument if FACT = 'F';
  otherwise, R is an output argument.  If FACT = 'F' and
  EQUED = 'R' or 'B', each element of R must be positive.
  If R is output, each element of R is a power of the radix.
  If R is input, each element of R should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A.  If EQUED = 'C' or 'B', A is
  multiplied on the right by diag(C); if EQUED = 'N' or 'R', C
  is not accessed.  C is an input argument if FACT = 'F';
  otherwise, C is an output argument.  If FACT = 'F' and
  EQUED = 'C' or 'B', each element of C must be positive.
  If C is output, each element of C is a power of the radix.
  If C is input, each element of C should be a power of the radix
  to ensure a reliable solution and error estimates. Scaling by
  powers of the radix does not cause rounding errors unless the
  result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
```

```
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is COMPLEX*16 array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
         max_j (abs(XTRUE(j,i) - X(j,i)))
          ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * dlamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.
```

```
  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * dlamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * dlamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * dlamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
```

```
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
```

```
   guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
       has been completed, but the factor U is exactly singular, so
       the solution and error bounds could not be computed. RCOND = 0
       is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
       not guaranteed. The solutions corresponding to other right-
       hand sides K with K > J may not be guaranteed as well, but
       only the first such right-hand side is reported. If a small
       componentwise error is not requested (PARAMS(3) = 0.0) then
       the Jth right-hand side is the first with a normwise error
       bound that is not guaranteed (the smallest J such
       that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
       the Jth right-hand side is the first with either a normwise or
       componentwise error bound that is not guaranteed (the smallest
       J such that either ERR_BNDS_NORM(J,1) = 0.0 or
       ERR_BNDS_COMP(J,1) = 0.0). See the definition of
       ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
       about all of the right-hand sides check ERR_BNDS_NORM or
       ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine zgbtf2 (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           ZGBTF2 computes the LU factorization of a general band matrix using
           the unblocked version of the algorithm.

Function/Subroutine Documentation
   subroutine zgbtf2 (integer M, integer N, integer KL, integer KU,
       complex*16, dimension( ldab, * ) AB, integer LDAB, integer, dimension(
       * ) IPIV, integer INFO)
       ZGBTF2 computes the LU factorization of a general band matrix using the
       unblocked version of the algorithm.

Purpose:
   ZGBTF2 computes an LU factorization of a complex m-by-n band matrix
   A using partial pivoting with row interchanges.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows KL+1 to
   2*KL+KU+1; rows 1 to KL of the array need not be set.
   The j-th column of A is stored in the j-th column of the
```

```
  array AB as follows:
  AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

 LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

 IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.

Further Details:

  The band storage scheme is illustrated by the following example, when
  M = N = 6, KL = 2, KU = 1:

       On entry:                       On exit:

           *    *    *    +    +    +       *    *    *   u14  u25  u36
           *    *    +    +    +    +       *    *   u13  u24  u35  u46
           *   a12  a23  a34  a45  a56       *   u12  u23  u34  u45  u56
          a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
          a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
          a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

  Array elements marked * are not used by the routine; elements marked
  + need not be set on entry, but are required by the routine to store
  elements of U, because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbtrf (M, N, KL, KU, AB, LDAB, IPIV, INFO)
           ZGBTRF

Function/Subroutine Documentation
   subroutine zgbtrf (integer M, integer N, integer KL, integer KU,
       complex*16, dimension( ldab, * ) AB, integer LDAB, integer, dimension(
       * ) IPIV, integer INFO)
       ZGBTRF

Purpose:
   ZGBTRF computes an LU factorization of a complex m-by-n band matrix A
   using partial pivoting with row interchanges.

   This is the blocked version of the algorithm, calling Level 3 BLAS.
```

```
Parameters:

M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows KL+1 to
  2*KL+KU+1; rows 1 to KL of the array need not be set.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

  On exit, details of the factorization: U is stored as an
  upper triangular band matrix with KL+KU superdiagonals in
  rows 1 to KL+KU+1, and the multipliers used during the
  factorization are stored in rows KL+KU+2 to 2*KL+KU+1.
  See below for further details.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (min(M,N))
  The pivot indices; for 1 <= i <= min(M,N), row i of the
  matrix was interchanged with row IPIV(i).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = +i, U(i,i) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.
```

```
Further Details:

   The band storage scheme is illustrated by the following example, when
   M = N = 6, KL = 2, KU = 1:

        On entry:                       On exit:

            *    *    *    +    +    +       *    *    *   u14  u25  u36
            *    *    +    +    +    +       *    *   u13  u24  u35  u46
            *   a12  a23  a34  a45  a56      *   u12  u23  u34  u45  u56
           a11  a22  a33  a44  a55  a66     u11  u22  u33  u44  u55  u66
           a21  a32  a43  a54  a65   *      m21  m32  m43  m54  m65   *
           a31  a42  a53  a64   *    *      m31  m42  m53  m64   *    *

   Array elements marked * are not used by the routine; elements marked
   + need not be set on entry, but are required by the routine to store
   elements of U because of fill-in resulting from the row interchanges.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgbtrs (TRANS, N, KL, KU, NRHS, AB, LDAB, IPIV, B, LDB,
           INFO)
           ZGBTRS
```

```
Function/Subroutine Documentation
   subroutine zgbtrs (character TRANS, integer N, integer KL, integer KU,
       integer NRHS, complex*16, dimension( ldab, * ) AB, integer LDAB,
       integer, dimension( * ) IPIV, complex*16, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       ZGBTRS

Purpose:
   ZGBTRS solves a system of linear equations
   A * X = B,  A**T * X = B,  or  A**H * X = B
   with a general band matrix A using the LU factorization computed by ZGBTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   Details of the LU factorization of the band matrix A, as
   computed by ZGBTRF.  U is stored as an upper triangular band
   matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and
   the multipliers used during the factorization are stored in
   rows KL+KU+2 to 2*KL+KU+1.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= 2*KL+KU+1.
```

```
 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices; for 1 <= i <= N, row i of the matrix was
   interchanged with row IPIV(i).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zggbak (JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V, LDV,
           INFO)
           ZGGBAK

Function/Subroutine Documentation
   subroutine zggbak (character JOB, character SIDE, integer N, integer ILO,
       integer IHI, double precision, dimension( * ) LSCALE, double precision,
       dimension( * ) RSCALE, integer M, complex*16, dimension( ldv, * ) V,
       integer LDV, integer INFO)
       ZGGBAK

Purpose:
   ZGGBAK forms the right or left eigenvectors of a complex generalized
   eigenvalue problem A*x = lambda*B*x, by backward transformation on
   the computed eigenvectors of the balanced pair of matrices output by
   ZGGBAL.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the type of backward transformation required:
   = 'N':  do nothing, return immediately;
```

```
  = 'P':  do backward transformation for permutation only;
  = 'S':  do backward transformation for scaling only;
  = 'B':  do backward transformations for both permutation and scaling.
  JOB must be the same as the argument JOB supplied to ZGGBAL.

SIDE
  SIDE is CHARACTER*1
  = 'R':  V contains right eigenvectors;
  = 'L':  V contains left eigenvectors.

N
  N is INTEGER
  The number of rows of the matrix V.  N >= 0.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  The integers ILO and IHI determined by ZGGBAL.
  1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE
  LSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and/or scaling factors applied
  to the left side of A and B, as returned by ZGGBAL.

RSCALE
  RSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and/or scaling factors applied
  to the right side of A and B, as returned by ZGGBAL.

M
  M is INTEGER
  The number of columns of the matrix V.  M >= 0.

V
  V is COMPLEX*16 array, dimension (LDV,M)
  On entry, the matrix of right or left eigenvectors to be
  transformed, as returned by ZTGEVC.
  On exit, V is overwritten by the transformed eigenvectors.

LDV
  LDV is INTEGER
  The leading dimension of the matrix V. LDV >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zggbal (JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
           WORK, INFO)
```

```
          ZGGBAL

Function/Subroutine Documentation
   subroutine zggbal (character JOB, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, complex*16, dimension( ldb, * ) B, integer LDB,
       integer ILO, integer IHI, double precision, dimension( * ) LSCALE,
       double precision, dimension( * ) RSCALE, double precision, dimension( *
       ) WORK, integer INFO)
       ZGGBAL

Purpose:
   ZGGBAL balances a pair of general complex matrices (A,B).  This
   involves, first, permuting A and B by similarity transformations to
   isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N
   elements on the diagonal; and second, applying a diagonal similarity
   transformation to rows and columns ILO to IHI to make the rows
   and columns as close in norm as possible. Both steps are optional.

   Balancing may reduce the 1-norm of the matrices, and improve the
   accuracy of the computed eigenvalues and/or eigenvectors in the
   generalized eigenvalue problem A*x = lambda*B*x.

Parameters:

 JOB
   JOB is CHARACTER*1
   Specifies the operations to be performed on A and B:
   = 'N':  none:  simply set ILO = 1, IHI = N, LSCALE(I) = 1.0
           and RSCALE(I) = 1.0 for i=1,...,N;
   = 'P':  permute only;
   = 'S':  scale only;
   = 'B':  both permute and scale.

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the input matrix A.
   On exit, A is overwritten by the balanced matrix.
   If JOB = 'N', A is not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,N).

 B
   B is COMPLEX*16 array, dimension (LDB,N)
   On entry, the input matrix B.
```

```
  On exit, B is overwritten by the balanced matrix.
  If JOB = 'N', B is not referenced.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  ILO and IHI are set to integers such that on exit
  A(i,j) = 0 and B(i,j) = 0 if i > j and
  j = 1,...,ILO-1 or i = IHI+1,...,N.
  If JOB = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE
  LSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the left side of A and B.  If P(j) is the index of the
  row interchanged with row j, and D(j) is the scaling factor
  applied to row j, then
  LSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

RSCALE
  RSCALE is DOUBLE PRECISION array, dimension (N)
  Details of the permutations and scaling factors applied
  to the right side of A and B.  If P(j) is the index of the
  column interchanged with column j, and D(j) is the scaling
  factor applied to column j, then
  RSCALE(j) = P(j)    for J = 1,...,ILO-1
            = D(j)    for J = ILO,...,IHI
            = P(j)    for J = IHI+1,...,N.
  The order in which the interchanges are made is N to IHI+1,
  then 1 to ILO-1.

WORK
  WORK is REAL array, dimension (lwork)
  lwork must be at least max(1,6*N) when JOB = 'S' or 'B', and
  at least 1 when JOB = 'N' or 'P'.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
   Functions/Subroutines
       subroutine zla_gbamv (TRANS, M, N, KL, KU, ALPHA, AB, LDAB, X, INCX,
           BETA, Y, INCY)
           ZLA_GBAMV performs a matrix-vector operation to calculate error
           bounds.

Function/Subroutine Documentation
   subroutine zla_gbamv (integer TRANS, integer M, integer N, integer KL,
       integer KU, double precision ALPHA, complex*16, dimension( ldab, * )
       AB, integer LDAB, complex*16, dimension( * ) X, integer INCX, double
       precision BETA, double precision, dimension( * ) Y, integer INCY)
       ZLA_GBAMV performs a matrix-vector operation to calculate error bounds.

Purpose:
   ZLA_GBAMV  performs one of the matrix-vector operations

        y := alpha*abs(A)*abs(x) + beta*abs(y),
   or   y := alpha*abs(A)**T*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   m by n matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 TRANS
   TRANS is INTEGER
   On entry, TRANS specifies the operation to be performed as
   follows:

   BLAS_NO_TRANS      y := alpha*abs(A)*abs(x) + beta*abs(y)
   BLAS_TRANS         y := alpha*abs(A**T)*abs(x) + beta*abs(y)
   BLAS_CONJ_TRANS    y := alpha*abs(A**T)*abs(x) + beta*abs(y)

   Unchanged on exit.

 M
```

```
  M is INTEGER
  On entry, M specifies the number of rows of the matrix A.
  M must be at least zero.
  Unchanged on exit.

N
  N is INTEGER
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

ALPHA
  ALPHA is DOUBLE PRECISION
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

AB
  AB is COMPLEX*16 array of DIMENSION ( LDAB, n )
  Before entry, the leading m by n part of the array AB must
  contain the matrix of coefficients.
  Unchanged on exit.

LDAB
  LDAB is INTEGER
  On entry, LDAB specifies the first dimension of AB as declared
  in the calling (sub) program. LDAB must be at least max( 1, m ).
  Unchanged on exit.

X
  X is COMPLEX*16 array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) ) when TRANS = 'N' or 'n'
  and at least
  ( 1 + ( m - 1 )*abs( INCX ) ) otherwise.
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.
```

```
 BETA
   BETA is DOUBLE PRECISION
   On entry, BETA specifies the scalar beta. When BETA is
   supplied as zero then Y need not be set on input.
   Unchanged on exit.

 Y
   Y is DOUBLE PRECISION array, dimension
   ( 1 + ( m - 1 )*abs( INCY ) ) when TRANS = 'N' or 'n'
   and at least
   ( 1 + ( n - 1 )*abs( INCY ) ) otherwise.
   Before entry with BETA non-zero, the incremented array Y
   must contain the vector y. On exit, Y is overwritten by the
   updated vector y.

 INCY
   INCY is INTEGER
   On entry, INCY specifies the increment for the elements of
   Y. INCY must not be zero.
   Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_gbrcond_c (TRANS, N, KL, KU, AB, LDAB,
           AFB, LDAFB, IPIV, C, CAPPLY, INFO, WORK, RWORK)
           ZLA_GBRCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for general banded matrices.

Function/Subroutine Documentation
   double precision function zla_gbrcond_c (character TRANS, integer N,
```

```
      integer KL, integer KU, complex*16, dimension( ldab, * ) AB, integer
      LDAB, complex*16, dimension( ldafb, * ) AFB, integer LDAFB, integer,
      dimension( * ) IPIV, double precision, dimension( * ) C, logical
      CAPPLY, integer INFO, complex*16, dimension( * ) WORK, double
      precision, dimension( * ) RWORK)
      ZLA_GBRCOND_C computes the infinity norm condition number of
      op(A)*inv(diag(c)) for general banded matrices.

Purpose:
   ZLA_GBRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= KL+KU+1.

 AFB
   AFB is COMPLEX*16 array, dimension (LDAFB,N)
   Details of the LU factorization of the band matrix A, as
   computed by ZGBTRF.  U is stored as an upper triangular
   band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
```

```
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by ZGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * inv(diag(C)).

CAPPLY
  CAPPLY is LOGICAL
  If .TRUE. then access the vector C in the formula above.

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX*16 array, dimension (2*N).
  Workspace.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_gbrcond_x (TRANS, N, KL, KU, AB, LDAB,
           AFB, LDAFB, IPIV, X, INFO, WORK, RWORK)
           ZLA_GBRCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for general banded matrices.

Function/Subroutine Documentation
   double precision function zla_gbrcond_x (character TRANS, integer N,
       integer KL, integer KU, complex*16, dimension( ldab, * ) AB, integer
       LDAB, complex*16, dimension( ldafb, * ) AFB, integer LDAFB, integer,
       dimension( * ) IPIV, complex*16, dimension( * ) X, integer INFO,
       complex*16, dimension( * ) WORK, double precision, dimension( * )
       RWORK)
       ZLA_GBRCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for general banded matrices.

Purpose:
   ZLA_GBRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX*16 vector.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate Transpose = Transpose)

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
```

```
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
  The j-th column of A is stored in the j-th column of the
  array AB as follows:
  AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

AFB
  AFB is COMPLEX*16 array, dimension (LDAFB,N)
  Details of the LU factorization of the band matrix A, as
  computed by ZGBTRF.  U is stored as an upper triangular
  band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
  and the multipliers used during the factorization are stored
  in rows KL+KU+2 to 2*KL+KU+1.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
  as computed by ZGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

X
  X is COMPLEX*16 array, dimension (N)
  The vector X in the formula op(A) * diag(X).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX*16 array, dimension (2*N).
  Workspace.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N).
```

```
Workspace.

       ZLA_GBRFSX_EXTENDED improves the computed solution to a system of
       linear equations for general banded matrices by performing extra-
       precise iterative refinement and provides error bounds and backward
       error estimates for the solution.

Purpose:
   ZLA_GBRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by ZGBRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
```

```
  P    = 'S':  Single
       = 'D':  Double
       = 'I':  Indigenous
       = 'X', 'E':  Extra

TRANS_TYPE
  TRANS_TYPE is INTEGER
  Specifies the transposition operation on A.
  The value is defined by ILATRANS(T) where T is a CHARACTER and
  T    = 'N':  No transpose
       = 'T':  Transpose
       = 'C':  Conjugate transpose

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

KL
  KL is INTEGER
  The number of subdiagonals within the band of A.  KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals within the band of A.  KU >= 0

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  On entry, the N-by-N matrix A.

LDAB
  LDAB is INTEGER
  The leading dimension of the array A.  LDAB >= max(1,N).

AFB
  AFB is COMPLEX*16 array, dimension (LDAF,N)
  The factors L and U from the factorization
  A = P*L*U as computed by ZGBTRF.

LDAFB
  LDAFB is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices from the factorization A = P*L*U
```

```
  as computed by ZGBTRF; row i of the matrix was interchanged
  with row IPIV(i).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX*16 array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by ZGBTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.
```

```
ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                     abs(XTRUE(j,i) - X(j,i))
```

```
                max_j ----------------------
                           abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace.

DY
  DY is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate solution.
```

```
Y_TAIL
  Y_TAIL is COMPLEX*16 array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-
  conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is DOUBLE PRECISION
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is DOUBLE PRECISION
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
```

```
= 0:  Successful exit.
< 0:  if INFO = -i, the ith argument to ZGBTRS had an illegal value
```

SYNOPSIS
   Functions/Subroutines
```

```
      double precision function zla_gbrpvgrw (N, KL, KU, NCOLS, AB, LDAB,
          AFB, LDAFB)
          ZLA_GBRPVGRW computes the reciprocal pivot growth factor
          norm(A)/norm(U) for a general banded matrix.

Function/Subroutine Documentation
   double precision function zla_gbrpvgrw (integer N, integer KL, integer KU,
       integer NCOLS, complex*16, dimension( ldab, * ) AB, integer LDAB,
       complex*16, dimension( ldafb, * ) AFB, integer LDAFB)
       ZLA_GBRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a general banded matrix.

Purpose:
   ZLA_GBRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A.  NCOLS >= 0.

 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDAB >= KL+KU+1.
```

```
 AFB
   AFB is COMPLEX*16 array, dimension (LDAFB,N)
   Details of the LU factorization of the band matrix A, as
   computed by ZGBTRF.  U is stored as an upper triangular
   band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1,
   and the multipliers used during the factorization are stored
   in rows KL+KU+2 to 2*KL+KU+1.

 LDAFB
   LDAFB is INTEGER
   The leading dimension of the array AFB.  LDAFB >= 2*KL+KU+1.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zungbr (VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
           ZUNGBR

Function/Subroutine Documentation
   subroutine zungbr (character VECT, integer M, integer N, integer K,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       * ) TAU, complex*16, dimension( * ) WORK, integer LWORK, integer INFO)
       ZUNGBR

Purpose:
   ZUNGBR generates one of the complex unitary matrices Q or P**H
   determined by ZGEBRD when reducing a complex matrix A to bidiagonal
   form: A = Q * B * P**H.  Q and P**H are defined as products of
   elementary reflectors H(i) or G(i) respectively.

   If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q
   is of order M:
   if m >= k, Q = H(1) H(2) . . . H(k) and ZUNGBR returns the first n
   columns of Q, where m >= n >= k;
   if m < k, Q = H(1) H(2) . . . H(m-1) and ZUNGBR returns Q as an
   M-by-M matrix.

   If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**H
   is of order N:
   if k < n, P**H = G(k) . . . G(2) G(1) and ZUNGBR returns the first m
   rows of P**H, where n >= m >= k;
   if k >= n, P**H = G(n-1) . . . G(2) G(1) and ZUNGBR returns P**H as
   an N-by-N matrix.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether the matrix Q or the matrix P**H is
   required, as defined in the transformation applied by ZGEBRD:
```

```
  = 'Q':  generate Q;
  = 'P':  generate P**H.

M
  M is INTEGER
  The number of rows of the matrix Q or P**H to be returned.
  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix Q or P**H to be returned.
  N >= 0.
  If VECT = 'Q', M >= N >= min(M,K);
  if VECT = 'P', N >= M >= min(N,K).

K
  K is INTEGER
  If VECT = 'Q', the number of columns in the original M-by-K
  matrix reduced by ZGEBRD.
  If VECT = 'P', the number of rows in the original K-by-N
  matrix reduced by ZGEBRD.
  K >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the vectors which define the elementary reflectors,
  as returned by ZGEBRD.
  On exit, the M-by-N matrix Q or P**H.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= M.

TAU
  TAU is COMPLEX*16 array, dimension
     (min(M,K)) if VECT = 'Q'
     (min(N,K)) if VECT = 'P'
  TAU(i) must contain the scalar factor of the elementary
  reflector H(i) or G(i), which determines Q or P**H, as
  returned by ZGEBRD in its array argument TAUQ or TAUP.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK >= max(1,min(M,N)).
  For optimum performance LWORK >= min(M,N)*NB, where NB
  is the optimal blocksize.
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       double precision function dlangb (NORM, N, KL, KU, AB, LDAB, WORK)
           DLANGB returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of general band
           matrix.

Function/Subroutine Documentation
   double precision function dlangb (character NORM, integer N, integer KL,
       integer KU, double precision, dimension( ldab, * ) AB, integer LDAB,
       double precision, dimension( * ) WORK)
       DLANGB returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of general band matrix.

Purpose:
   DLANGB  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the element of  largest absolute value  of an
   n by n band matrix  A,  with kl sub-diagonals and ku super-diagonals.

 Returns:

   DLANGB

       DLANGB = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in DLANGB as described above.

 N
```

```
  N is INTEGER
  The order of the matrix A.  N >= 0.  When N = 0, DLANGB is set to zero.

KL
  KL is INTEGER
  The number of sub-diagonals of the matrix A.  KL >= 0.

KU
  KU is INTEGER
  The number of super-diagonals of the matrix A.  KU >= 0.

AB
  AB is DOUBLE PRECISION array, dimension (LDAB,N)
  The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
  column of A is stored in the j-th column of the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlaqgb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           EQUED)
           DLAQGB scales a general band matrix, using row and column scaling
           factors computed by sgbequ.

Function/Subroutine Documentation
   subroutine dlaqgb (integer M, integer N, integer KL, integer KU, double
       precision, dimension( ldab, * ) AB, integer LDAB, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision
       ROWCND, double precision COLCND, double precision AMAX, character
       EQUED)
       DLAQGB scales a general band matrix, using row and column scaling
       factors computed by sgbequ.

Purpose:
   DLAQGB equilibrates a general M by N band matrix A with KL
   subdiagonals and KU superdiagonals using the row and scaling factors
   in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is DOUBLE PRECISION array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)
```

```
   On exit, the equilibrated matrix, in the same storage format
   as A.  See EQUED for the form of the equilibrated matrix.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDA >= KL+KU+1.

 R
   R is DOUBLE PRECISION array, dimension (M)
   The row scale factors for A.

 C
   C is DOUBLE PRECISION array, dimension (N)
   The column scale factors for A.

 ROWCND
   ROWCND is DOUBLE PRECISION
   Ratio of the smallest R(i) to the largest R(i).

 COLCND
   COLCND is DOUBLE PRECISION
   Ratio of the smallest C(i) to the largest C(i).

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:

   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       real function slangb (NORM, N, KL, KU, AB, LDAB, WORK)
           SLANGB returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of general band
           matrix.

Function/Subroutine Documentation
   real function slangb (character NORM, integer N, integer KL, integer KU,
       real, dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) WORK)
       SLANGB returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of general band matrix.

Purpose:
   SLANGB  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the element of  largest absolute value  of an
   n by n band matrix  A,  with kl sub-diagonals and ku super-diagonals.

 Returns:

   SLANGB

       SLANGB = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in SLANGB as described above.

 N
   N is INTEGER
```

```
  The order of the matrix A.  N >= 0.  When N = 0, SLANGB is set to zero.

KL
  KL is INTEGER
  The number of sub-diagonals of the matrix A.  KL >= 0.

KU
  KU is INTEGER
  The number of super-diagonals of the matrix A.  KU >= 0.

AB
  AB is REAL array, dimension (LDAB,N)
  The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
  column of A is stored in the j-th column of the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slaqgb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           EQUED)
           SLAQGB scales a general band matrix, using row and column scaling
           factors computed by sgbequ.

Function/Subroutine Documentation
   subroutine slaqgb (integer M, integer N, integer KL, integer KU, real,
       dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) R, real,
       dimension( * ) C, real ROWCND, real COLCND, real AMAX, character EQUED)
       SLAQGB scales a general band matrix, using row and column scaling
```

```
      factors computed by sgbequ.

Purpose:
   SLAQGB equilibrates a general M by N band matrix A with KL
   subdiagonals and KU superdiagonals using the row and scaling factors
   in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is REAL array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

   On exit, the equilibrated matrix, in the same storage format
   as A.  See EQUED for the form of the equilibrated matrix.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDA >= KL+KU+1.

 R
   R is REAL array, dimension (M)
   The row scale factors for A.

 C
   C is REAL array, dimension (N)
   The column scale factors for A.

 ROWCND
   ROWCND is REAL
   Ratio of the smallest R(i) to the largest R(i).
```

```
 COLCND
   COLCND is REAL
   Ratio of the smallest C(i) to the largest C(i).

 AMAX
   AMAX is REAL
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:

   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       real function clangb (NORM, N, KL, KU, AB, LDAB, WORK)
           CLANGB returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of general band
           matrix.

Function/Subroutine Documentation
   real function clangb (character NORM, integer N, integer KL, integer KU,
       complex, dimension( ldab, * ) AB, integer LDAB, real, dimension( * )
       WORK)
       CLANGB returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of general band matrix.

Purpose:
   CLANGB  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the element of  largest absolute value  of an
   n by n band matrix  A,  with kl sub-diagonals and ku super-diagonals.

 Returns:

   CLANGB

       CLANGB = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in CLANGB as described above.

 N
```

```
  N is INTEGER
  The order of the matrix A.  N >= 0.  When N = 0, CLANGB is set to zero.

KL
  KL is INTEGER
  The number of sub-diagonals of the matrix A.  KL >= 0.

KU
  KU is INTEGER
  The number of super-diagonals of the matrix A.  KU >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
  column of A is stored in the j-th column of the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.
```

SYNOPSIS
   Functions/Subroutines
       subroutine claqgb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           EQUED)
           CLAQGB scales a general band matrix, using row and column scaling
           factors computed by sgbequ.

Function/Subroutine Documentation
   subroutine claqgb (integer M, integer N, integer KL, integer KU, complex,
       dimension( ldab, * ) AB, integer LDAB, real, dimension( * ) R, real,
       dimension( * ) C, real ROWCND, real COLCND, real AMAX, character EQUED)
       CLAQGB scales a general band matrix, using row and column scaling
       factors computed by sgbequ.

Purpose:
   CLAQGB equilibrates a general M by N band matrix A with KL
   subdiagonals and KU superdiagonals using the row and scaling factors
   in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
   array AB as follows:
   AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)
```

```
  On exit, the equilibrated matrix, in the same storage format
  as A.  See EQUED for the form of the equilibrated matrix.

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDA >= KL+KU+1.

R
  R is REAL array, dimension (M)
  The row scale factors for A.

C
  C is REAL array, dimension (N)
  The column scale factors for A.

ROWCND
  ROWCND is REAL
  Ratio of the smallest R(i) to the largest R(i).

COLCND
  COLCND is REAL
  Ratio of the smallest C(i) to the largest C(i).

AMAX
  AMAX is REAL
  Absolute value of largest matrix entry.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration
  = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
  = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
  = 'B':  Both row and column equilibration, i.e., A has been
          replaced by diag(R) * A * diag(C).

Internal Parameters:

  THRESH is a threshold value used to decide if row or column scaling
  should be done based on the ratio of the row or column scaling
  factors.  If ROWCND < THRESH, row scaling is done, and if
  COLCND < THRESH, column scaling is done.

  LARGE and SMALL are threshold values used to decide if row scaling
  should be done based on the absolute size of the largest matrix
  element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       double precision function zlangb (NORM, N, KL, KU, AB, LDAB, WORK)
           ZLANGB returns the value of the 1-norm, Frobenius norm, infinity-
           norm, or the largest absolute value of any element of general band
           matrix.

Function/Subroutine Documentation
   double precision function zlangb (character NORM, integer N, integer KL,
       integer KU, complex*16, dimension( ldab, * ) AB, integer LDAB, double
       precision, dimension( * ) WORK)
       ZLANGB returns the value of the 1-norm, Frobenius norm, infinity-norm,
       or the largest absolute value of any element of general band matrix.

Purpose:
   ZLANGB  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the element of  largest absolute value  of an
   n by n band matrix  A,  with kl sub-diagonals and ku super-diagonals.

 Returns:

   ZLANGB

       ZLANGB = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in ZLANGB as described above.

 N
```

```
  N is INTEGER
  The order of the matrix A.  N >= 0.  When N = 0, ZLANGB is set to zero.

KL
  KL is INTEGER
  The number of sub-diagonals of the matrix A.  KL >= 0.

KU
  KU is INTEGER
  The number of super-diagonals of the matrix A.  KU >= 0.

AB
  AB is COMPLEX*16 array, dimension (LDAB,N)
  The band matrix A, stored in rows 1 to KL+KU+1.  The j-th
  column of A is stored in the j-th column of the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDAB
  LDAB is INTEGER
  The leading dimension of the array AB.  LDAB >= KL+KU+1.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I'; otherwise, WORK is not referenced.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zlaqgb (M, N, KL, KU, AB, LDAB, R, C, ROWCND, COLCND, AMAX,
           EQUED)
           ZLAQGB scales a general band matrix, using row and column scaling
           factors computed by sgbequ.

Function/Subroutine Documentation
   subroutine zlaqgb (integer M, integer N, integer KL, integer KU,
       complex*16, dimension( ldab, * ) AB, integer LDAB, double precision,
       dimension( * ) R, double precision, dimension( * ) C, double precision
       ROWCND, double precision COLCND, double precision AMAX, character
       EQUED)
       ZLAQGB scales a general band matrix, using row and column scaling
       factors computed by sgbequ.

Purpose:
   ZLAQGB equilibrates a general M by N band matrix A with KL
   subdiagonals and KU superdiagonals using the row and scaling factors
   in the vectors R and C.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 KL
   KL is INTEGER
   The number of subdiagonals within the band of A.  KL >= 0.

 KU
   KU is INTEGER
   The number of superdiagonals within the band of A.  KU >= 0.

 AB
   AB is COMPLEX*16 array, dimension (LDAB,N)
   On entry, the matrix A in band storage, in rows 1 to KL+KU+1.
   The j-th column of A is stored in the j-th column of the
```

```
   array AB as follows:
   AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

   On exit, the equilibrated matrix, in the same storage format
   as A.  See EQUED for the form of the equilibrated matrix.

 LDAB
   LDAB is INTEGER
   The leading dimension of the array AB.  LDA >= KL+KU+1.

 R
   R is DOUBLE PRECISION array, dimension (M)
   The row scale factors for A.

 C
   C is DOUBLE PRECISION array, dimension (N)
   The column scale factors for A.

 ROWCND
   ROWCND is DOUBLE PRECISION
   Ratio of the smallest R(i) to the largest R(i).

 COLCND
   COLCND is DOUBLE PRECISION
   Ratio of the smallest C(i) to the largest C(i).

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done.
   = 'N':  No equilibration
   = 'R':  Row equilibration, i.e., A has been premultiplied by diag(R).
   = 'C':  Column equilibration, i.e., A has been postmultiplied by diag(C).
   = 'B':  Both row and column equilibration, i.e., A has been
           replaced by diag(R) * A * diag(C).

Internal Parameters:

   THRESH is a threshold value used to decide if row or column scaling
   should be done based on the ratio of the row or column scaling
   factors.  If ROWCND < THRESH, row scaling is done, and if
   COLCND < THRESH, column scaling is done.

   LARGE and SMALL are threshold values used to decide if row scaling
   should be done based on the absolute size of the largest matrix
   element.  If AMAX > LARGE or AMAX < SMALL, row scaling is done.

SYNOPSIS
   Functions/Subroutines
       subroutine dsysv (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK,
           INFO)
            DSYSV computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine dsysv (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
        DSYSV computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   DSYSV computes the solution to a real system of linear equations
      A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.  The factored form of A is then
   used to solve the system of equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by DSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D, as
  determined by DSYTRF.  If IPIV(k) > 0, then rows and columns
  k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1
  diagonal block.  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0,
  then rows and columns k-1 and -IPIV(k) were interchanged and
  D(k-1:k,k-1:k) is a 2-by-2 diagonal block.  If UPLO = 'L' and
  IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and
  -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2
  diagonal block.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= 1, and for best performance
  LWORK >= max(1,N*NB), where NB is the optimal blocksize for
  DSYTRF.
  for LWORK < N, TRS will be done with Level BLAS 2
  for LWORK >= N, TRS will be done with Level BLAS 3
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular, so the solution could not be computed.

SYNOPSIS
   Functions/Subroutines
       subroutine dsysv_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK,
```

```
          LWORK, INFO)
           DSYSV_ROOK computes the solution to system of linear equations A *
          X = B for SY matrices

Function/Subroutine Documentation
   subroutine dsysv_rook (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
        DSYSV_ROOK computes the solution to system of linear equations A * X =
       B for SY matrices

Purpose:
   DSYSV_ROOK computes the solution to a real system of linear
   equations
   A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   DSYTRF_ROOK is called to compute the factorization of a real
   symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method.

   The factored form of A is then used to solve the system
   of equations A * X = B by calling DSYTRS_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
```

```
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by DSYTRF_ROOK.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D,
  as determined by DSYTRF_ROOK.

  If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
```

```
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= 1, and for best performance
  LWORK >= max(1,N*NB), where NB is the optimal blocksize for
  DSYTRF_ROOK.

  TRS will be done with Level 2 BLAS

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsysvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB,
           X, LDX, RCOND, FERR, BERR, WORK, LWORK, IWORK, INFO)
            DSYSVX computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine dsysvx (character FACT, character UPLO, integer N, integer NRHS,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV,
       double precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( ldx, * ) X, integer LDX, double precision RCOND, double
       precision, dimension( * ) FERR, double precision, dimension( * ) BERR,
       double precision, dimension( * ) WORK, integer LWORK, integer,
       dimension( * ) IWORK, integer INFO)
```

```
       DSYSVX computes the solution to system of linear equations A * X = B
      for SY matrices

Purpose:
   DSYSVX uses the diagonal pivoting factorization to compute the
   solution to a real system of linear equations A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the diagonal pivoting method is used to factor A.
      The form of the factorization is
         A = U * D * U**T,  if UPLO = 'U', or
         A = L * D * L**T,  if UPLO = 'L',
      where U (or L) is a product of permutation and unit upper (lower)
      triangular matrices, and D is symmetric and block diagonal with
      1-by-1 and 2-by-2 diagonal blocks.

   2. If some D(i,i)=0, so that D is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  On entry, AF and IPIV contain the factored form of
           A.  AF and IPIV will not be modified.
   = 'N':  The matrix A will be copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.
```

```
N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T as computed by DSYTRF.

  If FACT = 'N', then AF is an output argument and on exit
  returns the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains details of the interchanges and the block structure
  of D, as determined by DSYTRF.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
```

```
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains details of the interchanges and the block structure
  of D, as determined by DSYTRF.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The length of WORK.  LWORK >= max(1,3*N), and for best
   performance, when FACT = 'N', LWORK >= max(1,3*N,N*NB), where
   NB is the optimal blocksize for DSYTRF.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, and i is
     <= N:  D(i,i) is exactly zero.  The factorization
        has been completed but the factor D is exactly
        singular, so the solution and error bounds could
        not be computed. RCOND = 0 is returned.
     = N+1: D is nonsingular, but RCOND is less than machine
        precision, meaning that the matrix is singular
        to working precision.  Nevertheless, the
        solution and error bounds are computed because
        there are a number of situations where the
        computed solution can be more accurate than the
        value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine ssysv (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK,
           INFO)
            SSYSV computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine ssysv (character UPLO, integer N, integer NRHS, real, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real, dimension(
       ldb, * ) B, integer LDB, real, dimension( * ) WORK, integer LWORK,
       integer INFO)
        SSYSV computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   SSYSV computes the solution to a real system of linear equations
     A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
     A = U * D * U**T,  if UPLO = 'U', or
     A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.  The factored form of A is then
   used to solve the system of equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D, as
  determined by SSYTRF.  If IPIV(k) > 0, then rows and columns
  k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1
  diagonal block.  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0,
  then rows and columns k-1 and -IPIV(k) were interchanged and
  D(k-1:k,k-1:k) is a 2-by-2 diagonal block.  If UPLO = 'L' and
  IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and
  -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= 1, and for best performance
  LWORK >= max(1,N*NB), where NB is the optimal blocksize for
  SSYTRF.
  for LWORK < N, TRS will be done with Level BLAS 2
  for LWORK >= N, TRS will be done with Level BLAS 3
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssysv_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK,
           LWORK, INFO)
```

```
           SSYSV_ROOK computes the solution to system of linear equations A *
          X = B for SY matrices

Function/Subroutine Documentation
   subroutine ssysv_rook (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, real, dimension( * ) WORK, integer
       LWORK, integer INFO)
        SSYSV_ROOK computes the solution to system of linear equations A * X =
       B for SY matrices

Purpose:
   SSYSV_ROOK computes the solution to a real system of linear equations
      A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   SSYTRF_ROOK is called to compute the factorization of a real
   symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method.

   The factored form of A is then used to solve the system
   of equations A * X = B by calling SSYTRS_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
```

```
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF_ROOK.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D,
  as determined by SSYTRF_ROOK.

  If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.
```

```
 LWORK
   LWORK is INTEGER
   The length of WORK.  LWORK >= 1, and for best performance
   LWORK >= max(1,N*NB), where NB is the optimal blocksize for SSYTRF_ROOK.

   TRS will be done with Level 2 BLAS

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssysvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB,
           X, LDX, RCOND, FERR, BERR, WORK, LWORK, IWORK, INFO)
            SSYSVX computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine ssysvx (character FACT, character UPLO, integer N, integer NRHS,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * )
       AF, integer LDAF, integer, dimension( * ) IPIV, real, dimension( ldb, *
       ) B, integer LDB, real, dimension( ldx, * ) X, integer LDX, real RCOND,
       real, dimension( * ) FERR, real, dimension( * ) BERR, real, dimension(
       * ) WORK, integer LWORK, integer, dimension( * ) IWORK, integer INFO)
        SSYSVX computes the solution to system of linear equations A * X = B
       for SY matrices
```

```
Purpose:
   SSYSVX uses the diagonal pivoting factorization to compute the
   solution to a real system of linear equations A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the diagonal pivoting method is used to factor A.
      The form of the factorization is
        A = U * D * U**T,  if UPLO = 'U', or
        A = L * D * L**T,  if UPLO = 'L',
      where U (or L) is a product of permutation and unit upper (lower)
      triangular matrices, and D is symmetric and block diagonal with
      1-by-1 and 2-by-2 diagonal blocks.

   2. If some D(i,i)=0, so that D is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           AF and IPIV will not be modified.
   = 'N':  The matrix A will be copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
```

```
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is REAL array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is REAL array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.

  If FACT = 'N', then AF is an output argument and on exit
  returns the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains details of the interchanges and the block structure
  of D, as determined by SSYTRF.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.
```

```
  If FACT = 'N', then IPIV is an output argument and on exit
  contains details of the interchanges and the block structure
  of D, as determined by SSYTRF.

B
  B is REAL array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
```

```
  The length of WORK.  LWORK >= max(1,3*N), and for best
  performance, when FACT = 'N', LWORK >= max(1,3*N,N*NB), where
  NB is the optimal blocksize for SSYTRF.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
    <= N:  D(i,i) is exactly zero.  The factorization
       has been completed but the factor D is exactly
       singular, so the solution and error bounds could
       not be computed. RCOND = 0 is returned.
    = N+1: D is nonsingular, but RCOND is less than machine
       precision, meaning that the matrix is singular
       to working precision.  Nevertheless, the
       solution and error bounds are computed because
       there are a number of situations where the
       computed solution can be more accurate than the
       value of RCOND would suggest.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csysv (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK,
           INFO)
            CSYSV computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine csysv (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, complex, dimension( * )
       WORK, integer LWORK, integer INFO)
        CSYSV computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   CSYSV computes the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.  The factored form of A is then
   used to solve the system of equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D, as
  determined by CSYTRF.  If IPIV(k) > 0, then rows and columns
  k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1
  diagonal block.  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0,
  then rows and columns k-1 and -IPIV(k) were interchanged and
  D(k-1:k,k-1:k) is a 2-by-2 diagonal block.  If UPLO = 'L' and
  IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and
  -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2
  diagonal block.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= 1, and for best performance
  LWORK >= max(1,N*NB), where NB is the optimal blocksize for
  CSYTRF.
  for LWORK < N, TRS will be done with Level BLAS 2
  for LWORK >= N, TRS will be done with Level BLAS 3
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csysv_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK,
           LWORK, INFO)
            CSYSV_ROOK computes the solution to system of linear equations A *
           X = B for SY matrices

Function/Subroutine Documentation
   subroutine csysv_rook (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, complex, dimension( * )
       WORK, integer LWORK, integer INFO)
        CSYSV_ROOK computes the solution to system of linear equations A * X =
       B for SY matrices

Purpose:
   CSYSV_ROOK computes the solution to a complex system of linear
   equations
     A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
     A = U * D * U**T,  if UPLO = 'U', or
     A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   CSYTRF_ROOK is called to compute the factorization of a complex
   symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method.

   The factored form of A is then used to solve the system
   of equations A * X = B by calling CSYTRS_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
```

```
  of the matrix B.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF_ROOK.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D,
  as determined by CSYTRF_ROOK.

  If UPLO = 'U':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k-1 and -IPIV(k-1) were inerchaged,
    D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k+1 and -IPIV(k+1) were inerchaged,
    D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
```

```
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= 1, and for best performance
  LWORK >= max(1,N*NB), where NB is the optimal blocksize for
  CSYTRF_ROOK.

  TRS will be done with Level 2 BLAS

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csysvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB,
           X, LDX, RCOND, FERR, BERR, WORK, LWORK, RWORK, INFO)
            CSYSVX computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
```

```
   subroutine csysvx (character FACT, character UPLO, integer N, integer NRHS,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( ldaf,
       * ) AF, integer LDAF, integer, dimension( * ) IPIV, complex, dimension(
       ldb, * ) B, integer LDB, complex, dimension( ldx, * ) X, integer LDX,
       real RCOND, real, dimension( * ) FERR, real, dimension( * ) BERR,
       complex, dimension( * ) WORK, integer LWORK, real, dimension( * )
       RWORK, integer INFO)
        CSYSVX computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   CSYSVX uses the diagonal pivoting factorization to compute the
   solution to a complex system of linear equations A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the diagonal pivoting method is used to factor A.
      The form of the factorization is
        A = U * D * U**T,  if UPLO = 'U', or
        A = L * D * L**T,  if UPLO = 'L',
      where U (or L) is a product of permutation and unit upper (lower)
      triangular matrices, and D is symmetric and block diagonal with
      1-by-1 and 2-by-2 diagonal blocks.

   2. If some D(i,i)=0, so that D is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           A, AF and IPIV will not be modified.
```

```
  = 'N':  The matrix A will be copied to AF and factored.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

  If FACT = 'N', then AF is an output argument and on exit
  returns the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains details of the interchanges and the block structure
```

```
  of D, as determined by CSYTRF.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains details of the interchanges and the block structure
  of D, as determined by CSYTRF.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
```

```
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= max(1,2*N), and for best
  performance, when FACT = 'N', LWORK >= max(1,2*N,N*NB), where
  NB is the optimal blocksize for CSYTRF.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
    <= N:  D(i,i) is exactly zero.  The factorization
       has been completed but the factor D is exactly
       singular, so the solution and error bounds could
       not be computed. RCOND = 0 is returned.
    = N+1: D is nonsingular, but RCOND is less than machine
       precision, meaning that the matrix is singular
       to working precision.  Nevertheless, the
       solution and error bounds are computed because
       there are a number of situations where the
       computed solution can be more accurate than the
       value of RCOND would suggest.

       integer NPARAMS, real, dimension( * ) PARAMS, complex, dimension( * )
       WORK, real, dimension( * ) RWORK, integer INFO)
        CSYSVXX computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   CSYSVXX uses the diagonal pivoting factorization to compute the
   solution to a complex system of linear equations A * X = B, where
   A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CSYSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CSYSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CSYSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CSYSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

      diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as

      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
```

```
      where U (or L) is a product of permutation and unit upper (lower)
      triangular matrices, and D is symmetric and block diagonal with
      1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND).  If the reciprocal of the condition number is
      less than machine precision, the routine still goes on to solve
      for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(R) so that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by S.
      A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
```

```
  The number of linear equations, i.e., the order of the  matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular
  part of the matrix A, and the strictly lower triangular
  part of A is not referenced.  If UPLO = 'L', the leading
  N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the block diagonal matrix D and the multipliers
  used to obtain the factor U or L from the factorization A =
  U*D*U**T or A = L*D*L**T as computed by SSYTRF.

  If FACT = 'N', then AF is an output argument and on exit
  returns the block diagonal matrix D and the multipliers
  used to obtain the factor U or L from the factorization A =
  U*D*U**T or A = L*D*L**T.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains details of the interchanges and the block
  structure of D, as determined by SSYTRF.  If IPIV(k) > 0,
  then rows and columns k and IPIV(k) were interchanged and
  D(k,k) is a 1-by-1 diagonal block.  If UPLO = 'U' and
  IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and
  -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2
  diagonal block.  If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0,
```

```
  then rows and columns k+1 and -IPIV(k) were interchanged
  and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains details of the interchanges and the block
  structure of D, as determined by SSYTRF.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Both row and column equilibration, i.e., A has been
  replaced by diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is REAL array, dimension (N)
  The scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit if
  EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(S))*X.

LDX
  LDX is INTEGER
```

```
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.
```

```
  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP

  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
```

```
      reciprocal condition number is less than the threshold
      sqrt(n) * slamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
      sqrt(n) * slamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * slamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*(A*diag(x)), where x is the solution for the
      current right-hand side and S scales each row of
      A*diag(x) by a power of the radix so all absolute row
      sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.
```

```
  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
     componentwise error is not requested (PARAMS(3) = 0.0) then
     the Jth right-hand side is the first with a normwise error
     bound that is not guaranteed (the smallest J such
     that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
     the Jth right-hand side is the first with either a normwise or
     componentwise error bound that is not guaranteed (the smallest
     J such that either ERR_BNDS_NORM(J,1) = 0.0 or
     ERR_BNDS_COMP(J,1) = 0.0). See the definition of
     ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
     about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine zsysv (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK,
           INFO)
            ZSYSV computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine zsysv (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB, complex*16, dimension(
       * ) WORK, integer LWORK, integer INFO)
        ZSYSV computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   ZSYSV computes the solution to a complex system of linear equations
     A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
     A = U * D * U**T,  if UPLO = 'U', or
     A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.  The factored form of A is then
   used to solve the system of equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by ZSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D, as
  determined by ZSYTRF.  If IPIV(k) > 0, then rows and columns
  k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1
  diagonal block.  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0,
  then rows and columns k-1 and -IPIV(k) were interchanged and
  D(k-1:k,k-1:k) is a 2-by-2 diagonal block.  If UPLO = 'L' and
  IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and
  -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2
  diagonal block.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= 1, and for best performance
  LWORK >= max(1,N*NB), where NB is the optimal blocksize for
  ZSYTRF.
  for LWORK < N, TRS will be done with Level BLAS 2
  for LWORK >= N, TRS will be done with Level BLAS 3
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsysv_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK,
           LWORK, INFO)
            ZSYSV_ROOK computes the solution to system of linear equations A *
           X = B for SY matrices

Function/Subroutine Documentation
   subroutine zsysv_rook (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB, complex*16, dimension(
       * ) WORK, integer LWORK, integer INFO)
        ZSYSV_ROOK computes the solution to system of linear equations A * X =
       B for SY matrices

Purpose:
   ZSYSV_ROOK computes the solution to a complex system of linear equations
     A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   The diagonal pivoting method is used to factor A as
     A = U * D * U**T,  if UPLO = 'U', or
     A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   ZSYTRF_ROOK is called to compute the factorization of a complex
   symmetric matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method.

   The factored form of A is then used to solve the system
   of equations A * X = B by calling ZSYTRS_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.
```

```
A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the block diagonal matrix D and the
  multipliers used to obtain the factor U or L from the
  factorization A = U*D*U**T or A = L*D*L**T as computed by ZSYTRF_ROOK.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D,
  as determined by ZSYTRF_ROOK.

  If UPLO = 'U':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k-1 and -IPIV(k-1) were inerchaged,
    D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k+1 and -IPIV(k+1) were inerchaged,
    D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

```
 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of WORK.  LWORK >= 1, and for best performance
   LWORK >= max(1,N*NB), where NB is the optimal blocksize for
   ZSYTRF_ROOK.

   TRS will be done with Level 2 BLAS

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular, so the solution could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsysvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB,
           X, LDX, RCOND, FERR, BERR, WORK, LWORK, RWORK, INFO)
            ZSYSVX computes the solution to system of linear equations A * X =
           B for SY matrices

Function/Subroutine Documentation
   subroutine zsysvx (character FACT, character UPLO, integer N, integer NRHS,
```

```
      complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
      ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, complex*16,
      dimension( ldb, * ) B, integer LDB, complex*16, dimension( ldx, * ) X,
      integer LDX, double precision RCOND, double precision, dimension( * )
      FERR, double precision, dimension( * ) BERR, complex*16, dimension( * )
      WORK, integer LWORK, double precision, dimension( * ) RWORK, integer
      INFO)
       ZSYSVX computes the solution to system of linear equations A * X = B
      for SY matrices

Purpose:
   ZSYSVX uses the diagonal pivoting factorization to compute the
   solution to a complex system of linear equations A * X = B,
   where A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the diagonal pivoting method is used to factor A.
      The form of the factorization is
        A = U * D * U**T,  if UPLO = 'U', or
        A = L * D * L**T,  if UPLO = 'L',
      where U (or L) is a product of permutation and unit upper (lower)
      triangular matrices, and D is symmetric and block diagonal with
      1-by-1 and 2-by-2 diagonal blocks.

   2. If some D(i,i)=0, so that D is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           A, AF and IPIV will not be modified.
```

```
  = 'N':  The matrix A will be copied to AF and factored.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T as computed by ZSYTRF.

  If FACT = 'N', then AF is an output argument and on exit
  returns the block diagonal matrix D and the multipliers used
  to obtain the factor U or L from the factorization
  A = U*D*U**T or A = L*D*L**T.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains details of the interchanges and the block structure
```

```
  of D, as determined by ZSYTRF.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains details of the interchanges and the block structure
  of D, as determined by ZSYTRF.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
```

```
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >= max(1,2*N), and for best
  performance, when FACT = 'N', LWORK >= max(1,2*N,N*NB), where
  NB is the optimal blocksize for ZSYTRF.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
    <= N:  D(i,i) is exactly zero.  The factorization
       has been completed but the factor D is exactly
       singular, so the solution and error bounds could
       not be computed. RCOND = 0 is returned.
    = N+1: D is nonsingular, but RCOND is less than machine
       precision, meaning that the matrix is singular
       to working precision.  Nevertheless, the
       solution and error bounds are computed because
       there are a number of situations where the
       computed solution can be more accurate than the
       value of RCOND would suggest.

        ZSYSVXX computes the solution to system of linear equations A * X = B
       for SY matrices

Purpose:
   ZSYSVXX uses the diagonal pivoting factorization to compute the
   solution to a complex*16 system of linear equations A * X = B, where
   A is an N-by-N symmetric matrix and X and B are N-by-NRHS
   matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZSYSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZSYSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZSYSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZSYSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:

      diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

```
   2. If FACT = 'N' or 'E', the LU decomposition is used to factor
      the matrix A (after equilibration if FACT = 'E') as

   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',

      where U (or L) is a product of permutation and unit upper (lower)
      triangular matrices, and D is symmetric and block diagonal with
      1-by-1 and 2-by-2 diagonal blocks.

   3. If some D(i,i)=0, so that D is exactly singular, then the
      routine returns with INFO = i. Otherwise, the factored form of A
      is used to estimate the condition number of the matrix A (see
      argument RCOND).  If the reciprocal of the condition number is
      less than machine precision, the routine still goes on to solve
      for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(R) so that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF and IPIV contain the factored form of A.
           If EQUED is not 'N', the matrix A has been
           equilibrated with scaling factors given by S.
           A, AF, and IPIV are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
           copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
```

```
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular
  part of the matrix A, and the strictly lower triangular
  part of A is not referenced.  If UPLO = 'L', the leading
  N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the block diagonal matrix D and the multipliers
  used to obtain the factor U or L from the factorization A =
  U*D*U**T or A = L*D*L**T as computed by DSYTRF.

  If FACT = 'N', then AF is an output argument and on exit
  returns the block diagonal matrix D and the multipliers
  used to obtain the factor U or L from the factorization A =
  U*D*U**T or A = L*D*L**T.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains details of the interchanges and the block
  structure of D, as determined by DSYTRF.  If IPIV(k) > 0,
```

```
  then rows and columns k and IPIV(k) were interchanged and
  D(k,k) is a 1-by-1 diagonal block.  If UPLO = 'U' and
  IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and
  -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2
  diagonal block.  If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0,
  then rows and columns k+1 and -IPIV(k) were interchanged
  and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains details of the interchanges and the block
  structure of D, as determined by DSYTRF.

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Both row and column equilibration, i.e., A has been
          replaced by diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is DOUBLE PRECISION array, dimension (N)
  The scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit if
```

```
  EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))
```

```
  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                   abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
```

```
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
```

```
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be
              trustworthy.

 PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
   will attempt to find a solution with small componentwise
   relative error in the double-precision algorithm.  Positive
   is true, 0.0 is false.
   Default: 1.0 (attempt componentwise convergence)

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  Successful exit. The solution to every right-hand side is
   guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine dsyev (JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, INFO)
            DSYEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine dsyev (character JOBZ, character UPLO, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) W, double precision, dimension( * ) WORK, integer LWORK,
       integer INFO)
        DSYEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   DSYEV computes all eigenvalues and, optionally, eigenvectors of a
   real symmetric matrix A.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA, N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the
   leading N-by-N upper triangular part of A contains the
   upper triangular part of the matrix A.  If UPLO = 'L',
   the leading N-by-N lower triangular part of A contains
   the lower triangular part of the matrix A.
   On exit, if JOBZ = 'V', then if INFO = 0, A contains the
   orthonormal eigenvectors of the matrix A.
   If JOBZ = 'N', then on exit the lower triangle (if UPLO='L')
   or the upper triangle (if UPLO='U') of A, including the
```

```
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

W
  W is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,3*N-1).
  For optimal efficiency, LWORK >= (NB+2)*N,
  where NB is the blocksize for DSYTRD returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the algorithm failed to converge; i
        off-diagonal elements of an intermediate tridiagonal
        form did not converge to zero.

SYNOPSIS
   Functions/Subroutines
       subroutine dsyevd (JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK,
           LIWORK, INFO)
            DSYEVD computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine dsyevd (character JOBZ, character UPLO, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) W, double precision, dimension( * ) WORK, integer LWORK,
       integer, dimension( * ) IWORK, integer LIWORK, integer INFO)
        DSYEVD computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   DSYEVD computes all eigenvalues and, optionally, eigenvectors of a
   real symmetric matrix A. If eigenvectors are desired, it uses a
   divide and conquer algorithm.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

   Because of large use of BLAS of level 3, DSYEVD needs N**2 more
   workspace than DSYEVX.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.
```

```
UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.
  On exit, if JOBZ = 'V', then if INFO = 0, A contains the
  orthonormal eigenvectors of the matrix A.
  If JOBZ = 'N', then on exit the lower triangle (if UPLO='L')
  or the upper triangle (if UPLO='U') of A, including the
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

W
  W is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is DOUBLE PRECISION array, dimension (LWORK)
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N <= 1,               LWORK must be at least 1.
  If JOBZ = 'N' and N > 1, LWORK must be at least 2*N+1.
  If JOBZ = 'V' and N > 1, LWORK must be at least
  1 + 6*N + 2*N**2.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal sizes of the WORK and IWORK
  arrays, returns these values as the first entries of the WORK
  and IWORK arrays, and no error message related to LWORK or
  LIWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
```

```
  On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  If N <= 1,                LIWORK must be at least 1.
  If JOBZ  = 'N' and N > 1, LIWORK must be at least 1.
  If JOBZ  = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the optimal sizes of the WORK and
  IWORK arrays, returns these values as the first entries of
  the WORK and IWORK arrays, and no error message related to
  LWORK or LIWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i and JOBZ = 'N', then the algorithm failed
        to converge; i off-diagonal elements of an intermediate
        tridiagonal form did not converge to zero;
        if INFO = i and JOBZ = 'V', then the algorithm failed
        to compute an eigenvalue while working on the submatrix
        lying in rows and columns INFO/(N+1) through
        mod(INFO,N+1).
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsyevr (JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU,
           ABSTOL, M, W, Z, LDZ, ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
            DSYEVR computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine dsyevr (character JOBZ, character RANGE, character UPLO, integer
       N, double precision, dimension( lda, * ) A, integer LDA, double
       precision VL, double precision VU, integer IL, integer IU, double
       precision ABSTOL, integer M, double precision, dimension( * ) W, double
       precision, dimension( ldz, * ) Z, integer LDZ, integer, dimension( * )
       ISUPPZ, double precision, dimension( * ) WORK, integer LWORK, integer,
       dimension( * ) IWORK, integer LIWORK, integer INFO)
        DSYEVR computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

       Purpose:
   DSYEVR computes selected eigenvalues and, optionally, eigenvectors
   of a real symmetric matrix A.  Eigenvalues and eigenvectors can be
   selected by specifying either a range of values or a range of
   indices for the desired eigenvalues.

   DSYEVR first reduces the matrix A to tridiagonal form T with a call
   to DSYTRD.  Then, whenever possible, DSYEVR calls DSTEMR to compute
   the eigenspectrum using Relatively Robust Representations.  DSTEMR
   computes eigenvalues by the dqds algorithm, while orthogonal
   eigenvectors are computed from various "good" L D L^T representations
   (also known as Relatively Robust Representations). Gram-Schmidt
   orthogonalization is avoided as far as possible. More specifically,
   the various steps of the algorithm are as follows.

   For each unreduced block (submatrix) of T,
   (a) Compute T - sigma I  = L D L^T, so that L and D
       define all the wanted eigenvalues to high relative accuracy.
       This means that small relative changes in the entries of D and L
       cause only small relative changes in the eigenvalues and
       eigenvectors. The standard (unfactored) representation of the
       tridiagonal matrix T does not have this property in general.
   (b) Compute the eigenvalues to suitable accuracy.
       If the eigenvectors are desired, the algorithm attains full
```

```
      accuracy of the computed eigenvalues only right before
      the corresponding vectors have to be computed, see steps c) and d).
  (c) For each cluster of close eigenvalues, select a new
      shift close to the cluster, find a new factorization, and refine
      the shifted eigenvalues to suitable accuracy.
  (d) For each eigenvalue with a large enough relative separation compute
      the corresponding eigenvector by forming a rank revealing twisted
      factorization. Go back to (c) for any clusters that remain.

  The desired accuracy of the output can be specified by the input
  parameter ABSTOL.

  Note 1 : DSYEVR calls DSTEMR when the full spectrum is requested
  on machines which conform to the ieee-754 floating point standard.
  DSYEVR calls DSTEBZ and SSTEIN on non-ieee machines and
  when partial spectrum requests are made.

  Normal execution of DSTEMR may create NaNs and infinities and hence
  may abort due to a floating point exception in environments which
  do not handle NaNs and infinities in the ieee standard default
  manner.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 RANGE
   RANGE is CHARACTER*1
   = 'A': all eigenvalues will be found.
   = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
   = 'I': the IL-th through IU-th eigenvalues will be found.
   For RANGE = 'V' or 'I' and IU - IL < N - 1, DSTEBZ and DSTEIN are called

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA, N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the
   leading N-by-N upper triangular part of A contains the
   upper triangular part of the matrix A.  If UPLO = 'L',
```

```
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.
  On exit, the lower triangle (if UPLO='L') or the upper
  triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

VL
  VL is DOUBLE PRECISION

VU
  VU is DOUBLE PRECISION
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues. VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

ABSTOL
  ABSTOL is DOUBLE PRECISION
  The absolute error tolerance for the eigenvalues.
  An approximate eigenvalue is accepted as converged
  when it is determined to lie in an interval [a,b]
  of width less than or equal to

  ABSTOL + EPS *   max( |a|,|b| ) ,

  where EPS is the machine precision.  If ABSTOL is less than
  or equal to zero, then  EPS*|T|  will be used in its place,
  where |T| is the 1-norm of the tridiagonal matrix obtained
  by reducing A to tridiagonal form.

  See "Computing Small Singular Values of Bidiagonal Matrices
  with Guaranteed High Relative Accuracy," by Demmel and
  Kahan, LAPACK Working Note #3.

  If high relative accuracy is important, set ABSTOL to
  DLAMCH( 'Safe minimum' ).  Doing so will guarantee that
  eigenvalues are computed to high relative accuracy when
  possible in future releases.  The current code does not
```

```
  make any guarantees about high relative accuracy, but
  future releases will. See J. Barlow and J. Demmel,
  "Computing Accurate Eigensystems of Scaled Diagonally
  Dominant Matrices", LAPACK Working Note #7, for a discussion
  of which matrices define their eigenvalues to high relative accuracy.

M
  M is INTEGER
  The total number of eigenvalues found.  0 <= M <= N.
  If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W
  W is DOUBLE PRECISION array, dimension (N)
  The first M elements contain the selected eigenvalues in
  ascending order.

Z
  Z is DOUBLE PRECISION array, dimension (LDZ, max(1,M))
  If JOBZ = 'V', then if INFO = 0, the first M columns of Z
  contain the orthonormal eigenvectors of the matrix A
  corresponding to the selected eigenvalues, with the i-th
  column of Z holding the eigenvector associated with W(i).
  If JOBZ = 'N', then Z is not referenced.
  Note: the user must ensure that at least max(1,M) columns are
  supplied in the array Z; if RANGE = 'V', the exact value of M
  is not known in advance and an upper bound must be used.
  Supplying N columns is always safe.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ
  ISUPPZ is INTEGER array, dimension ( 2*max(1,M) )
  The support of the eigenvectors in Z, i.e., the indices
  indicating the nonzero elements in Z. The i-th eigenvector
  is nonzero only in elements ISUPPZ( 2*i-1 ) through ISUPPZ( 2*i ).
  Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,26*N).
  For optimal efficiency, LWORK >= (NB+6)*N,
  where NB is the max of the blocksize for DSYTRD and DORMTR
  returned by ILAENV.
```

```
  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.  LIWORK >= max(1,10*N).

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the optimal size of the IWORK array,
  returns this value as the first entry of the IWORK array, and
  no error message related to LIWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  Internal error
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsyevx (JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU,
           ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
            DSYEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine dsyevx (character JOBZ, character RANGE, character UPLO, integer
       N, double precision, dimension( lda, * ) A, integer LDA, double
       precision VL, double precision VU, integer IL, integer IU, double
       precision ABSTOL, integer M, double precision, dimension( * ) W, double
       precision, dimension( ldz, * ) Z, integer LDZ, double precision,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer, dimension( * ) IFAIL, integer INFO)
        DSYEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   DSYEVX computes selected eigenvalues and, optionally, eigenvectors
   of a real symmetric matrix A.  Eigenvalues and eigenvectors can be
   selected by specifying either a range of values or a range of indices
   for the desired eigenvalues.

Parameters:
```

```
JOBZ
  JOBZ is CHARACTER*1
  = 'N':  Compute eigenvalues only;
  = 'V':  Compute eigenvalues and eigenvectors.

RANGE
  RANGE is CHARACTER*1
  = 'A': all eigenvalues will be found.
  = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
  = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.
  On exit, the lower triangle (if UPLO='L') or the upper
  triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

VL
  VL is DOUBLE PRECISION

VU
  VU is DOUBLE PRECISION
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues. VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
```

```
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

ABSTOL
  ABSTOL is DOUBLE PRECISION
  The absolute error tolerance for the eigenvalues.
  An approximate eigenvalue is accepted as converged
  when it is determined to lie in an interval [a,b]
  of width less than or equal to

     ABSTOL + EPS *   max( |a|,|b| ) ,

  where EPS is the machine precision.  If ABSTOL is less than
  or equal to zero, then  EPS*|T|  will be used in its place,
  where |T| is the 1-norm of the tridiagonal matrix obtained
  by reducing A to tridiagonal form.

  Eigenvalues will be computed most accurately when ABSTOL is
  set to twice the underflow threshold 2*DLAMCH('S'), not zero.
  If this routine returns with INFO>0, indicating that some
  eigenvectors did not converge, try setting ABSTOL to
  2*DLAMCH('S').

M
  M is INTEGER
  The total number of eigenvalues found.  0 <= M <= N.
  If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W
  W is DOUBLE PRECISION array, dimension (N)
  On normal exit, the first M elements contain the selected
  eigenvalues in ascending order.

Z
  Z is DOUBLE PRECISION array, dimension (LDZ, max(1,M))
  If JOBZ = 'V', then if INFO = 0, the first M columns of Z
  contain the orthonormal eigenvectors of the matrix A
  corresponding to the selected eigenvalues, with the i-th
  column of Z holding the eigenvector associated with W(i).
  If an eigenvector fails to converge, then that column of Z
  contains the latest approximation to the eigenvector, and the
  index of the eigenvector is returned in IFAIL.
  If JOBZ = 'N', then Z is not referenced.
  Note: the user must ensure that at least max(1,M) columns are
  supplied in the array Z; if RANGE = 'V', the exact value of M
  is not known in advance and an upper bound must be used.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
```

```
  JOBZ = 'V', LDZ >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= 1, when N <= 1;
  otherwise 8*N.
  For optimal efficiency, LWORK >= (NB+3)*N,
  where NB is the max of the blocksize for DSYTRD and DORMTR
  returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (5*N)

IFAIL
  IFAIL is INTEGER array, dimension (N)
  If JOBZ = 'V', then if INFO = 0, the first M elements of
  IFAIL are zero.  If INFO > 0, then IFAIL contains the
  indices of the eigenvectors that failed to converge.
  If JOBZ = 'N', then IFAIL is not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, then i eigenvectors failed to converge.
        Their indices are stored in array IFAIL.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsygv (ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,
           INFO)
           DSYGV

Function/Subroutine Documentation
   subroutine dsygv (integer ITYPE, character JOBZ, character UPLO, integer N,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( * ) W,
       double precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DSYGV

Purpose:
   DSYGV computes all the eigenvalues, and optionally, the eigenvectors
   of a real generalized symmetric-definite eigenproblem, of the form
   A*x=(lambda)*B*x,  A*Bx=(lambda)*x,  or B*A*x=(lambda)*x.
   Here A and B are assumed to be symmetric and B is also positive definite.

Parameters:

 ITYPE
   ITYPE is INTEGER
   Specifies the problem type to be solved:
   = 1:  A*x = (lambda)*B*x
```

```
  = 2:  A*B*x = (lambda)*x
  = 3:  B*A*x = (lambda)*x

JOBZ
  JOBZ is CHARACTER*1
  = 'N':  Compute eigenvalues only;
  = 'V':  Compute eigenvalues and eigenvectors.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangles of A and B are stored;
  = 'L':  Lower triangles of A and B are stored.

N
  N is INTEGER
  The order of the matrices A and B.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.

  On exit, if JOBZ = 'V', then if INFO = 0, A contains the
  matrix Z of eigenvectors.  The eigenvectors are normalized
  as follows:
  if ITYPE = 1 or 2, Z**T*B*Z = I;
  if ITYPE = 3, Z**T*inv(B)*Z = I.
  If JOBZ = 'N', then on exit the upper triangle (if UPLO='U')
  or the lower triangle (if UPLO='L') of A, including the
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the symmetric positive definite matrix B.
  If UPLO = 'U', the leading N-by-N upper triangular part of B
  contains the upper triangular part of the matrix B.
  If UPLO = 'L', the leading N-by-N lower triangular part of B
  contains the lower triangular part of the matrix B.

  On exit, if INFO <= N, the part of B containing the matrix is
  overwritten by the triangular factor U or L from the Cholesky
  factorization B = U**T*U or B = L*L**T.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

W
  W is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,3*N-1).
  For optimal efficiency, LWORK >= (NB+2)*N,
  where NB is the blocksize for DSYTRD returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  DPOTRF or DSYEV returned an error code:
    <= N:  if INFO = i, DSYEV failed to converge;
           i off-diagonal elements of an intermediate
           tridiagonal form did not converge to zero;
    > N:   if INFO = N + i, for 1 <= i <= N, then the leading
           minor of order i of B is not positive definite.
           The factorization of B could not be completed and
           no eigenvalues or eigenvectors were computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsygvd (ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK,
           LWORK, IWORK, LIWORK, INFO)
           DSYGVD

Function/Subroutine Documentation
   subroutine dsygvd (integer ITYPE, character JOBZ, character UPLO, integer
       N, double precision, dimension( lda, * ) A, integer LDA, double
       precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( * ) W, double precision, dimension( * ) WORK, integer LWORK,
       integer, dimension( * ) IWORK, integer LIWORK, integer INFO)
       DSYGVD

Purpose:
   DSYGVD computes all the eigenvalues, and optionally, the eigenvectors
   of a real generalized symmetric-definite eigenproblem, of the form
   A*x=(lambda)*B*x,  A*Bx=(lambda)*x,  or B*A*x=(lambda)*x.  Here A and
   B are assumed to be symmetric and B is also positive definite.
   If eigenvectors are desired, it uses a divide and conquer algorithm.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 ITYPE
   ITYPE is INTEGER
   Specifies the problem type to be solved:
   = 1:  A*x = (lambda)*B*x
   = 2:  A*B*x = (lambda)*x
   = 3:  B*A*x = (lambda)*x
```

```
JOBZ
  JOBZ is CHARACTER*1
  = 'N':  Compute eigenvalues only;
  = 'V':  Compute eigenvalues and eigenvectors.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangles of A and B are stored;
  = 'L':  Lower triangles of A and B are stored.

N
  N is INTEGER
  The order of the matrices A and B.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.

  On exit, if JOBZ = 'V', then if INFO = 0, A contains the
  matrix Z of eigenvectors.  The eigenvectors are normalized
  as follows:
  if ITYPE = 1 or 2, Z**T*B*Z = I;
  if ITYPE = 3, Z**T*inv(B)*Z = I.
  If JOBZ = 'N', then on exit the upper triangle (if UPLO='U')
  or the lower triangle (if UPLO='L') of A, including the
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the symmetric matrix B.  If UPLO = 'U', the
  leading N-by-N upper triangular part of B contains the
  upper triangular part of the matrix B.  If UPLO = 'L',
  the leading N-by-N lower triangular part of B contains
  the lower triangular part of the matrix B.

  On exit, if INFO <= N, the part of B containing the matrix is
  overwritten by the triangular factor U or L from the Cholesky
  factorization B = U**T*U or B = L*L**T.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

```
W
  W is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N <= 1,               LWORK >= 1.
  If JOBZ = 'N' and N > 1, LWORK >= 2*N+1.
  If JOBZ = 'V' and N > 1, LWORK >= 1 + 6*N + 2*N**2.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal sizes of the WORK and IWORK
  arrays, returns these values as the first entries of the WORK
  and IWORK arrays, and no error message related to LWORK or
  LIWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  If N <= 1,                LIWORK >= 1.
  If JOBZ  = 'N' and N > 1, LIWORK >= 1.
  If JOBZ  = 'V' and N > 1, LIWORK >= 3 + 5*N.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the optimal sizes of the WORK and
  IWORK arrays, returns these values as the first entries of
  the WORK and IWORK arrays, and no error message related to
  LWORK or LIWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  DPOTRF or DSYEVD returned an error code:
    <= N:  if INFO = i and JOBZ = 'N', then the algorithm
           failed to converge; i off-diagonal elements of an
           intermediate tridiagonal form did not converge to zero;
           if INFO = i and JOBZ = 'V', then the algorithm
           failed to compute an eigenvalue while working on
           the submatrix lying in rows and columns INFO/(N+1)
```

```
            through mod(INFO,N+1);
     > N:   if INFO = N + i, for 1 <= i <= N, then the leading
            minor of order i of B is not positive definite.
            The factorization of B could not be completed and
            no eigenvalues or eigenvectors were computed.

Further Details:

   Modified so that no backsubstitution is performed if DSYEVD fails to
   converge (NEIG in old code could be greater than N causing out of
   bounds reference to A - reported by Ralf Meyer).  Also corrected the
   description of INFO and the test on ITYPE. Sven, 16 Feb 05.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsygvx (ITYPE, JOBZ, RANGE, UPLO, N, A, LDA, B, LDB, VL, VU,
           IL, IU, ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
           DSYGVX

Function/Subroutine Documentation
   subroutine dsygvx (integer ITYPE, character JOBZ, character RANGE,
       character UPLO, integer N, double precision, dimension( lda, * ) A,
       integer LDA, double precision, dimension( ldb, * ) B, integer LDB,
       double precision VL, double precision VU, integer IL, integer IU,
       double precision ABSTOL, integer M, double precision, dimension( * ) W,
       double precision, dimension( ldz, * ) Z, integer LDZ, double precision,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer, dimension( * ) IFAIL, integer INFO)
       DSYGVX

Purpose:
   DSYGVX computes selected eigenvalues, and optionally, eigenvectors
   of a real generalized symmetric-definite eigenproblem, of the form
   A*x=(lambda)*B*x,  A*Bx=(lambda)*x,  or B*A*x=(lambda)*x.  Here A
   and B are assumed to be symmetric and B is also positive definite.
   Eigenvalues and eigenvectors can be selected by specifying either a
   range of values or a range of indices for the desired eigenvalues.

Parameters:

 ITYPE
   ITYPE is INTEGER
```

```
  Specifies the problem type to be solved:
  = 1:  A*x = (lambda)*B*x
  = 2:  A*B*x = (lambda)*x
  = 3:  B*A*x = (lambda)*x

JOBZ
  JOBZ is CHARACTER*1
  = 'N':  Compute eigenvalues only;
  = 'V':  Compute eigenvalues and eigenvectors.

RANGE
  RANGE is CHARACTER*1
  = 'A': all eigenvalues will be found.
  = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
  = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A and B are stored;
  = 'L':  Lower triangle of A and B are stored.

N
  N is INTEGER
  The order of the matrix pencil (A,B).  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.

  On exit, the lower triangle (if UPLO='L') or the upper
  triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, the symmetric matrix B.  If UPLO = 'U', the
  leading N-by-N upper triangular part of B contains the
  upper triangular part of the matrix B.  If UPLO = 'L',
  the leading N-by-N lower triangular part of B contains
  the lower triangular part of the matrix B.

  On exit, if INFO <= N, the part of B containing the matrix is
  overwritten by the triangular factor U or L from the Cholesky
```

```
  factorization B = U**T*U or B = L*L**T.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

VL
  VL is DOUBLE PRECISION

VU
  VU is DOUBLE PRECISION
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues. VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

ABSTOL
  ABSTOL is DOUBLE PRECISION
  The absolute error tolerance for the eigenvalues.
  An approximate eigenvalue is accepted as converged
  when it is determined to lie in an interval [a,b]
  of width less than or equal to

  ABSTOL + EPS *   max( |a|,|b| ) ,

  where EPS is the machine precision.  If ABSTOL is less than
  or equal to zero, then  EPS*|T|  will be used in its place,
  where |T| is the 1-norm of the tridiagonal matrix obtained
  by reducing C to tridiagonal form, where C is the symmetric
  matrix of the standard symmetric problem to which the
  generalized problem is transformed.

  Eigenvalues will be computed most accurately when ABSTOL is
  set to twice the underflow threshold 2*DLAMCH('S'), not zero.
  If this routine returns with INFO>0, indicating that some
  eigenvectors did not converge, try setting ABSTOL to 2*DLAMCH('S').

M
  M is INTEGER
  The total number of eigenvalues found.  0 <= M <= N.
  If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.
```

```
W
  W is DOUBLE PRECISION array, dimension (N)
  On normal exit, the first M elements contain the selected
  eigenvalues in ascending order.

Z
  Z is DOUBLE PRECISION array, dimension (LDZ, max(1,M))
  If JOBZ = 'N', then Z is not referenced.
  If JOBZ = 'V', then if INFO = 0, the first M columns of Z
  contain the orthonormal eigenvectors of the matrix A
  corresponding to the selected eigenvalues, with the i-th
  column of Z holding the eigenvector associated with W(i).
  The eigenvectors are normalized as follows:
  if ITYPE = 1 or 2, Z**T*B*Z = I;
  if ITYPE = 3, Z**T*inv(B)*Z = I.

  If an eigenvector fails to converge, then that column of Z
  contains the latest approximation to the eigenvector, and the
  index of the eigenvector is returned in IFAIL.
  Note: the user must ensure that at least max(1,M) columns are
  supplied in the array Z; if RANGE = 'V', the exact value of M
  is not known in advance and an upper bound must be used.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  JOBZ = 'V', LDZ >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,8*N).
  For optimal efficiency, LWORK >= (NB+3)*N,
  where NB is the blocksize for DSYTRD returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (5*N)

IFAIL
  IFAIL is INTEGER array, dimension (N)
  If JOBZ = 'V', then if INFO = 0, the first M elements of
```

```
  IFAIL are zero.  If INFO > 0, then IFAIL contains the
  indices of the eigenvectors that failed to converge.
  If JOBZ = 'N', then IFAIL is not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  DPOTRF or DSYEVX returned an error code:
  <= N:  if INFO = i, DSYEVX failed to converge;
         i eigenvectors failed to converge.  Their indices
         are stored in array IFAIL.
  > N:   if INFO = N + i, for 1 <= i <= N, then the leading
         minor of order i of B is not positive definite.
         The factorization of B could not be completed and
         no eigenvalues or eigenvectors were computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyev (JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, INFO)
            SSYEV computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine ssyev (character JOBZ, character UPLO, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) W, real,
       dimension( * ) WORK, integer LWORK, integer INFO)
        SSYEV computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   SSYEV computes all eigenvalues and, optionally, eigenvectors of a
   real symmetric matrix A.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the
   leading N-by-N upper triangular part of A contains the
   upper triangular part of the matrix A.  If UPLO = 'L',
   the leading N-by-N lower triangular part of A contains
   the lower triangular part of the matrix A.
   On exit, if JOBZ = 'V', then if INFO = 0, A contains the
   orthonormal eigenvectors of the matrix A.
   If JOBZ = 'N', then on exit the lower triangle (if UPLO='L')
   or the upper triangle (if UPLO='U') of A, including the
   diagonal, is destroyed.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 W
   W is REAL array, dimension (N)
   If INFO = 0, the eigenvalues in ascending order.

 WORK
   WORK is REAL array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of the array WORK.  LWORK >= max(1,3*N-1).
   For optimal efficiency, LWORK >= (NB+2)*N,
   where NB is the blocksize for SSYTRD returned by ILAENV.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the algorithm failed to converge; i
         off-diagonal elements of an intermediate tridiagonal
         form did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyevd (JOBZ, UPLO, N, A, LDA, W, WORK, LWORK, IWORK,
           LIWORK, INFO)
            SSYEVD computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine ssyevd (character JOBZ, character UPLO, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) W, real,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer LIWORK, integer INFO)
        SSYEVD computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   SSYEVD computes all eigenvalues and, optionally, eigenvectors of a
   real symmetric matrix A. If eigenvectors are desired, it uses a
   divide and conquer algorithm.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

   Because of large use of BLAS of level 3, SSYEVD needs N**2 more
   workspace than SSYEVX.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.
```

```
UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.
  On exit, if JOBZ = 'V', then if INFO = 0, A contains the
  orthonormal eigenvectors of the matrix A.
  If JOBZ = 'N', then on exit the lower triangle (if UPLO='L')
  or the upper triangle (if UPLO='U') of A, including the
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

W
  W is REAL array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is REAL array, dimension (LWORK)
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N <= 1,               LWORK must be at least 1.
  If JOBZ = 'N' and N > 1, LWORK must be at least 2*N+1.
  If JOBZ = 'V' and N > 1, LWORK must be at least
  1 + 6*N + 2*N**2.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal sizes of the WORK and IWORK
  arrays, returns these values as the first entries of the WORK
  and IWORK arrays, and no error message related to LWORK or
  LIWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
```

```
  On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  If N <= 1,                LIWORK must be at least 1.
  If JOBZ  = 'N' and N > 1, LIWORK must be at least 1.
  If JOBZ  = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the optimal sizes of the WORK and
  IWORK arrays, returns these values as the first entries of
  the WORK and IWORK arrays, and no error message related to
  LWORK or LIWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i and JOBZ = 'N', then the algorithm failed
        to converge; i off-diagonal elements of an intermediate
        tridiagonal form did not converge to zero;
        if INFO = i and JOBZ = 'V', then the algorithm failed
        to compute an eigenvalue while working on the submatrix
        lying in rows and columns INFO/(N+1) through mod(INFO,N+1).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyevr (JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU,
           ABSTOL, M, W, Z, LDZ, ISUPPZ, WORK, LWORK, IWORK, LIWORK, INFO)
            SSYEVR computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine ssyevr (character JOBZ, character RANGE, character UPLO, integer
       N, real, dimension( lda, * ) A, integer LDA, real VL, real VU, integer
       IL, integer IU, real ABSTOL, integer M, real, dimension( * ) W, real,
       dimension( ldz, * ) Z, integer LDZ, integer, dimension( * ) ISUPPZ,
       real, dimension( * ) WORK, integer LWORK, integer, dimension( * )
       IWORK, integer LIWORK, integer INFO)
        SSYEVR computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   SSYEVR computes selected eigenvalues and, optionally, eigenvectors
   of a real symmetric matrix A.  Eigenvalues and eigenvectors can be
   selected by specifying either a range of values or a range of
   indices for the desired eigenvalues.

   SSYEVR first reduces the matrix A to tridiagonal form T with a call
   to SSYTRD.  Then, whenever possible, SSYEVR calls SSTEMR to compute
   the eigenspectrum using Relatively Robust Representations.  SSTEMR
   computes eigenvalues by the dqds algorithm, while orthogonal
   eigenvectors are computed from various "good" L D L^T representations
   (also known as Relatively Robust Representations). Gram-Schmidt
   orthogonalization is avoided as far as possible. More specifically,
   the various steps of the algorithm are as follows.

   For each unreduced block (submatrix) of T,
   (a) Compute T - sigma I  = L D L^T, so that L and D
       define all the wanted eigenvalues to high relative accuracy.
       This means that small relative changes in the entries of D and L
       cause only small relative changes in the eigenvalues and
       eigenvectors. The standard (unfactored) representation of the
       tridiagonal matrix T does not have this property in general.
   (b) Compute the eigenvalues to suitable accuracy.
       If the eigenvectors are desired, the algorithm attains full
       accuracy of the computed eigenvalues only right before
       the corresponding vectors have to be computed, see steps c) and d).
```

```
   (c) For each cluster of close eigenvalues, select a new
       shift close to the cluster, find a new factorization, and refine
       the shifted eigenvalues to suitable accuracy.
   (d) For each eigenvalue with a large enough relative separation compute
       the corresponding eigenvector by forming a rank revealing twisted
       factorization. Go back to (c) for any clusters that remain.

   The desired accuracy of the output can be specified by the input
   parameter ABSTOL.

   Note 1 : SSYEVR calls SSTEMR when the full spectrum is requested
   on machines which conform to the ieee-754 floating point standard.
   SSYEVR calls SSTEBZ and SSTEIN on non-ieee machines and
   when partial spectrum requests are made.

   Normal execution of SSTEMR may create NaNs and infinities and
   hence may abort due to a floating point exception in environments
   which do not handle NaNs and infinities in the ieee standard default
   manner.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 RANGE
   RANGE is CHARACTER*1
   = 'A': all eigenvalues will be found.
   = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
   = 'I': the IL-th through IU-th eigenvalues will be found.
   For RANGE = 'V' or 'I' and IU - IL < N - 1, SSTEBZ and SSTEIN are called

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the
   leading N-by-N upper triangular part of A contains the
   upper triangular part of the matrix A.  If UPLO = 'L',
   the leading N-by-N lower triangular part of A contains
   the lower triangular part of the matrix A.
```

```
  On exit, the lower triangle (if UPLO='L') or the upper
  triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

VL
  VL is REAL

VU
  VU is REAL
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues. VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

ABSTOL
  ABSTOL is REAL
  The absolute error tolerance for the eigenvalues.
  An approximate eigenvalue is accepted as converged
  when it is determined to lie in an interval [a,b]
  of width less than or equal to

  ABSTOL + EPS *   max( |a|,|b| ) ,

  where EPS is the machine precision.  If ABSTOL is less than
  or equal to zero, then  EPS*|T|  will be used in its place,
  where |T| is the 1-norm of the tridiagonal matrix obtained
  by reducing A to tridiagonal form.

  If high relative accuracy is important, set ABSTOL to
  SLAMCH( 'Safe minimum' ).  Doing so will guarantee that
  eigenvalues are computed to high relative accuracy when
  possible in future releases.  The current code does not
  make any guarantees about high relative accuracy, but
  future releases will. See J. Barlow and J. Demmel,
  "Computing Accurate Eigensystems of Scaled Diagonally
  Dominant Matrices", LAPACK Working Note #7, for a discussion
  of which matrices define their eigenvalues to high relative accuracy.
```

```
M
  M is INTEGER
  The total number of eigenvalues found.  0 <= M <= N.
  If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W
  W is REAL array, dimension (N)
  The first M elements contain the selected eigenvalues in
  ascending order.

Z
  Z is REAL array, dimension (LDZ, max(1,M))
  If JOBZ = 'V', then if INFO = 0, the first M columns of Z
  contain the orthonormal eigenvectors of the matrix A
  corresponding to the selected eigenvalues, with the i-th
  column of Z holding the eigenvector associated with W(i).
  If JOBZ = 'N', then Z is not referenced.
  Note: the user must ensure that at least max(1,M) columns are
  supplied in the array Z; if RANGE = 'V', the exact value of M
  is not known in advance and an upper bound must be used.
  Supplying N columns is always safe.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ
  ISUPPZ is INTEGER array, dimension ( 2*max(1,M) )
  The support of the eigenvectors in Z, i.e., the indices
  indicating the nonzero elements in Z. The i-th eigenvector
  is nonzero only in elements ISUPPZ( 2*i-1 ) through ISUPPZ( 2*i ).
  Implemented only for RANGE = 'A' or 'I' and IU - IL = N - 1

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= max(1,26*N).
  For optimal efficiency, LWORK >= (NB+6)*N,
  where NB is the max of the blocksize for SSYTRD and SORMTR
  returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal sizes of the WORK and IWORK
  arrays, returns these values as the first entries of the WORK
  and IWORK arrays, and no error message related to LWORK or
  LIWORK is issued by XERBLA.
```

```
 IWORK
   IWORK is INTEGER array, dimension (MAX(1,LIWORK))
   On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

 LIWORK
   LIWORK is INTEGER
   The dimension of the array IWORK.  LIWORK >= max(1,10*N).

   If LIWORK = -1, then a workspace query is assumed; the
   routine only calculates the optimal sizes of the WORK and
   IWORK arrays, returns these values as the first entries of
   the WORK and IWORK arrays, and no error message related to
   LWORK or LIWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  Internal error
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyevx (JOBZ, RANGE, UPLO, N, A, LDA, VL, VU, IL, IU,
           ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
            SSYEVX computes the eigenvalues and, optionally, the left and/or
           right eigenvectors for SY matrices

Function/Subroutine Documentation
   subroutine ssyevx (character JOBZ, character RANGE, character UPLO, integer
       N, real, dimension( lda, * ) A, integer LDA, real VL, real VU, integer
       IL, integer IU, real ABSTOL, integer M, real, dimension( * ) W, real,
       dimension( ldz, * ) Z, integer LDZ, real, dimension( * ) WORK, integer
       LWORK, integer, dimension( * ) IWORK, integer, dimension( * ) IFAIL,
       integer INFO)
        SSYEVX computes the eigenvalues and, optionally, the left and/or right
       eigenvectors for SY matrices

Purpose:
   SSYEVX computes selected eigenvalues and, optionally, eigenvectors
   of a real symmetric matrix A.  Eigenvalues and eigenvectors can be
   selected by specifying either a range of values or a range of indices
   for the desired eigenvalues.

Parameters:

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 RANGE
   RANGE is CHARACTER*1
   = 'A': all eigenvalues will be found.
   = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
```

```
  = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.
  On exit, the lower triangle (if UPLO='L') or the upper
  triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

VL
  VL is REAL

VU
  VU is REAL
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues. VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

ABSTOL
  ABSTOL is REAL
  The absolute error tolerance for the eigenvalues.
  An approximate eigenvalue is accepted as converged
  when it is determined to lie in an interval [a,b]
  of width less than or equal to
```

```
  ABSTOL + EPS *   max( |a|,|b| ) ,

  where EPS is the machine precision.  If ABSTOL is less than
  or equal to zero, then  EPS*|T|  will be used in its place,
  where |T| is the 1-norm of the tridiagonal matrix obtained
  by reducing A to tridiagonal form.

  Eigenvalues will be computed most accurately when ABSTOL is
  set to twice the underflow threshold 2*SLAMCH('S'), not zero.
  If this routine returns with INFO>0, indicating that some
  eigenvectors did not converge, try setting ABSTOL to
  2*SLAMCH('S').

M
  M is INTEGER
  The total number of eigenvalues found.  0 <= M <= N.
  If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W
  W is REAL array, dimension (N)
  On normal exit, the first M elements contain the selected
  eigenvalues in ascending order.

Z
  Z is REAL array, dimension (LDZ, max(1,M))
  If JOBZ = 'V', then if INFO = 0, the first M columns of Z
  contain the orthonormal eigenvectors of the matrix A
  corresponding to the selected eigenvalues, with the i-th
  column of Z holding the eigenvector associated with W(i).
  If an eigenvector fails to converge, then that column of Z
  contains the latest approximation to the eigenvector, and the
  index of the eigenvector is returned in IFAIL.
  If JOBZ = 'N', then Z is not referenced.
  Note: the user must ensure that at least max(1,M) columns are
  supplied in the array Z; if RANGE = 'V', the exact value of M
  is not known in advance and an upper bound must be used.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  JOBZ = 'V', LDZ >= max(1,N).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= 1, when N <= 1;
```

```
  otherwise 8*N.
  For optimal efficiency, LWORK >= (NB+3)*N,
  where NB is the max of the blocksize for SSYTRD and SORMTR
  returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (5*N)

IFAIL
  IFAIL is INTEGER array, dimension (N)
  If JOBZ = 'V', then if INFO = 0, the first M elements of
  IFAIL are zero.  If INFO > 0, then IFAIL contains the
  indices of the eigenvectors that failed to converge.
  If JOBZ = 'N', then IFAIL is not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, then i eigenvectors failed to converge.
        Their indices are stored in array IFAIL.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssygv (ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,
           INFO)
           SSYGV

Function/Subroutine Documentation
   subroutine ssygv (integer ITYPE, character JOBZ, character UPLO, integer N,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( * ) W, real, dimension( * ) WORK, integer
       LWORK, integer INFO)
       SSYGV

Purpose:
   SSYGV computes all the eigenvalues, and optionally, the eigenvectors
   of a real generalized symmetric-definite eigenproblem, of the form
   A*x=(lambda)*B*x,  A*Bx=(lambda)*x,  or B*A*x=(lambda)*x.
   Here A and B are assumed to be symmetric and B is also positive definite.

Parameters:

 ITYPE
   ITYPE is INTEGER
   Specifies the problem type to be solved:
   = 1:  A*x = (lambda)*B*x
   = 2:  A*B*x = (lambda)*x
   = 3:  B*A*x = (lambda)*x

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangles of A and B are stored;
   = 'L':  Lower triangles of A and B are stored.

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the
```

```
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.

  On exit, if JOBZ = 'V', then if INFO = 0, A contains the
  matrix Z of eigenvectors.  The eigenvectors are normalized
  as follows:
  if ITYPE = 1 or 2, Z**T*B*Z = I;
  if ITYPE = 3, Z**T*inv(B)*Z = I.
  If JOBZ = 'N', then on exit the upper triangle (if UPLO='U')
  or the lower triangle (if UPLO='L') of A, including the
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB, N)
  On entry, the symmetric positive definite matrix B.
  If UPLO = 'U', the leading N-by-N upper triangular part of B
  contains the upper triangular part of the matrix B.
  If UPLO = 'L', the leading N-by-N lower triangular part of B
  contains the lower triangular part of the matrix B.

  On exit, if INFO <= N, the part of B containing the matrix is
  overwritten by the triangular factor U or L from the Cholesky
  factorization B = U**T*U or B = L*L**T.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

W
  W is REAL array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,3*N-1).
  For optimal efficiency, LWORK >= (NB+2)*N,
  where NB is the blocksize for SSYTRD returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
```

```
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  SPOTRF or SSYEV returned an error code:
  <= N:  if INFO = i, SSYEV failed to converge;
         i off-diagonal elements of an intermediate
         tridiagonal form did not converge to zero;
  > N:   if INFO = N + i, for 1 <= i <= N, then the leading
         minor of order i of B is not positive definite.
         The factorization of B could not be completed and
         no eigenvalues or eigenvectors were computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssygvd (ITYPE, JOBZ, UPLO, N, A, LDA, B, LDB, W, WORK,
           LWORK, IWORK, LIWORK, INFO)
```

```
          SSYGVD

Function/Subroutine Documentation
   subroutine ssygvd (integer ITYPE, character JOBZ, character UPLO, integer
       N, real, dimension( lda, * ) A, integer LDA, real, dimension( ldb, * )
       B, integer LDB, real, dimension( * ) W, real, dimension( * ) WORK,
       integer LWORK, integer, dimension( * ) IWORK, integer LIWORK, integer
       INFO)
       SSYGVD

Purpose:
   SSYGVD computes all the eigenvalues, and optionally, the eigenvectors
   of a real generalized symmetric-definite eigenproblem, of the form
   A*x=(lambda)*B*x,  A*Bx=(lambda)*x,  or B*A*x=(lambda)*x.  Here A and
   B are assumed to be symmetric and B is also positive definite.
   If eigenvectors are desired, it uses a divide and conquer algorithm.

   The divide and conquer algorithm makes very mild assumptions about
   floating point arithmetic. It will work on machines with a guard
   digit in add/subtract, or on those binary machines without guard
   digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or
   Cray-2. It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

Parameters:

 ITYPE
   ITYPE is INTEGER
   Specifies the problem type to be solved:
   = 1:  A*x = (lambda)*B*x
   = 2:  A*B*x = (lambda)*x
   = 3:  B*A*x = (lambda)*x

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangles of A and B are stored;
   = 'L':  Lower triangles of A and B are stored.

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is REAL array, dimension (LDA, N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the
```

```
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.

  On exit, if JOBZ = 'V', then if INFO = 0, A contains the
  matrix Z of eigenvectors.  The eigenvectors are normalized
  as follows:
  if ITYPE = 1 or 2, Z**T*B*Z = I;
  if ITYPE = 3, Z**T*inv(B)*Z = I.
  If JOBZ = 'N', then on exit the upper triangle (if UPLO='U')
  or the lower triangle (if UPLO='L') of A, including the
  diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB, N)
  On entry, the symmetric matrix B.  If UPLO = 'U', the
  leading N-by-N upper triangular part of B contains the
  upper triangular part of the matrix B.  If UPLO = 'L',
  the leading N-by-N lower triangular part of B contains
  the lower triangular part of the matrix B.

  On exit, if INFO <= N, the part of B containing the matrix is
  overwritten by the triangular factor U or L from the Cholesky
  factorization B = U**T*U or B = L*L**T.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

W
  W is REAL array, dimension (N)
  If INFO = 0, the eigenvalues in ascending order.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  If N <= 1,               LWORK >= 1.
  If JOBZ = 'N' and N > 1, LWORK >= 2*N+1.
  If JOBZ = 'V' and N > 1, LWORK >= 1 + 6*N + 2*N**2.

  If LWORK = -1, then a workspace query is assumed; the routine
```

```
  only calculates the optimal sizes of the WORK and IWORK
  arrays, returns these values as the first entries of the WORK
  and IWORK arrays, and no error message related to LWORK or
  LIWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (MAX(1,LIWORK))
  On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK
  LIWORK is INTEGER
  The dimension of the array IWORK.
  If N <= 1,                LIWORK >= 1.
  If JOBZ  = 'N' and N > 1, LIWORK >= 1.
  If JOBZ  = 'V' and N > 1, LIWORK >= 3 + 5*N.

  If LIWORK = -1, then a workspace query is assumed; the
  routine only calculates the optimal sizes of the WORK and
  IWORK arrays, returns these values as the first entries of
  the WORK and IWORK arrays, and no error message related to
  LWORK or LIWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  SPOTRF or SSYEVD returned an error code:
  <= N:  if INFO = i and JOBZ = 'N', then the algorithm
     failed to converge; i off-diagonal elements of an
     intermediate tridiagonal form did not converge to zero;
     if INFO = i and JOBZ = 'V', then the algorithm
     failed to compute an eigenvalue while working on
     the submatrix lying in rows and columns INFO/(N+1)
     through mod(INFO,N+1);
  > N:   if INFO = N + i, for 1 <= i <= N, then the leading
     minor of order i of B is not positive definite.
     The factorization of B could not be completed and
     no eigenvalues or eigenvectors were computed.

SYNOPSIS
   Functions/Subroutines
       subroutine ssygvx (ITYPE, JOBZ, RANGE, UPLO, N, A, LDA, B, LDB, VL, VU,
           IL, IU, ABSTOL, M, W, Z, LDZ, WORK, LWORK, IWORK, IFAIL, INFO)
```

```
          SSYGVX

Function/Subroutine Documentation
   subroutine ssygvx (integer ITYPE, character JOBZ, character RANGE,
       character UPLO, integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( ldb, * ) B, integer LDB, real VL, real VU, integer IL,
       integer IU, real ABSTOL, integer M, real, dimension( * ) W, real,
       dimension( ldz, * ) Z, integer LDZ, real, dimension( * ) WORK, integer
       LWORK, integer, dimension( * ) IWORK, integer, dimension( * ) IFAIL,
       integer INFO)
       SSYGVX

Purpose:
   SSYGVX computes selected eigenvalues, and optionally, eigenvectors
