   of a real generalized symmetric-definite eigenproblem, of the form
   A*x=(lambda)*B*x,  A*Bx=(lambda)*x,  or B*A*x=(lambda)*x.  Here A
   and B are assumed to be symmetric and B is also positive definite.
   Eigenvalues and eigenvectors can be selected by specifying either a
   range of values or a range of indices for the desired eigenvalues.

Parameters:

 ITYPE
   ITYPE is INTEGER
   Specifies the problem type to be solved:
   = 1:  A*x = (lambda)*B*x
   = 2:  A*B*x = (lambda)*x
   = 3:  B*A*x = (lambda)*x

 JOBZ
   JOBZ is CHARACTER*1
   = 'N':  Compute eigenvalues only;
   = 'V':  Compute eigenvalues and eigenvectors.

 RANGE
   RANGE is CHARACTER*1
   = 'A': all eigenvalues will be found.
   = 'V': all eigenvalues in the half-open interval (VL,VU] will be found.
   = 'I': the IL-th through IU-th eigenvalues will be found.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A and B are stored;
   = 'L':  Lower triangle of A and B are stored.

 N
   N is INTEGER
   The order of the matrix pencil (A,B).  N >= 0.

 A
```

```
  A is REAL array, dimension (LDA, N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the
  leading N-by-N upper triangular part of A contains the
  upper triangular part of the matrix A.  If UPLO = 'L',
  the leading N-by-N lower triangular part of A contains
  the lower triangular part of the matrix A.

  On exit, the lower triangle (if UPLO='L') or the upper
  triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDA, N)
  On entry, the symmetric matrix B.  If UPLO = 'U', the
  leading N-by-N upper triangular part of B contains the
  upper triangular part of the matrix B.  If UPLO = 'L',
  the leading N-by-N lower triangular part of B contains
  the lower triangular part of the matrix B.

  On exit, if INFO <= N, the part of B containing the matrix is
  overwritten by the triangular factor U or L from the Cholesky
  factorization B = U**T*U or B = L*L**T.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

VL
  VL is REAL

VU
  VU is REAL
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues. VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

ABSTOL
```

```
  ABSTOL is REAL
  The absolute error tolerance for the eigenvalues.
  An approximate eigenvalue is accepted as converged
  when it is determined to lie in an interval [a,b]
  of width less than or equal to

  ABSTOL + EPS *   max( |a|,|b| ) ,

  where EPS is the machine precision.  If ABSTOL is less than
  or equal to zero, then  EPS*|T|  will be used in its place,
  where |T| is the 1-norm of the tridiagonal matrix obtained
  by reducing C to tridiagonal form, where C is the symmetric
  matrix of the standard symmetric problem to which the
  generalized problem is transformed.

  Eigenvalues will be computed most accurately when ABSTOL is
  set to twice the underflow threshold 2*DLAMCH('S'), not zero.
  If this routine returns with INFO>0, indicating that some
  eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M
  M is INTEGER
  The total number of eigenvalues found.  0 <= M <= N.
  If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W
  W is REAL array, dimension (N)
  On normal exit, the first M elements contain the selected
  eigenvalues in ascending order.

Z
  Z is REAL array, dimension (LDZ, max(1,M))
  If JOBZ = 'N', then Z is not referenced.
  If JOBZ = 'V', then if INFO = 0, the first M columns of Z
  contain the orthonormal eigenvectors of the matrix A
  corresponding to the selected eigenvalues, with the i-th
  column of Z holding the eigenvector associated with W(i).
  The eigenvectors are normalized as follows:
  if ITYPE = 1 or 2, Z**T*B*Z = I;
  if ITYPE = 3, Z**T*inv(B)*Z = I.

  If an eigenvector fails to converge, then that column of Z
  contains the latest approximation to the eigenvector, and the
  index of the eigenvector is returned in IFAIL.
  Note: the user must ensure that at least max(1,M) columns are
  supplied in the array Z; if RANGE = 'V', the exact value of M
  is not known in advance and an upper bound must be used.

LDZ
  LDZ is INTEGER
```

```
  The leading dimension of the array Z.  LDZ >= 1, and if
  JOBZ = 'V', LDZ >= max(1,N).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of the array WORK.  LWORK >= max(1,8*N).
  For optimal efficiency, LWORK >= (NB+3)*N,
  where NB is the blocksize for SSYTRD returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (5*N)

IFAIL
  IFAIL is INTEGER array, dimension (N)
  If JOBZ = 'V', then if INFO = 0, the first M elements of
  IFAIL are zero.  If INFO > 0, then IFAIL contains the
  indices of the eigenvectors that failed to converge.
  If JOBZ = 'N', then IFAIL is not referenced.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  SPOTRF or SSYEVX returned an error code:
  <= N:  if INFO = i, SSYEVX failed to converge;
        i eigenvectors failed to converge.  Their indices
        are stored in array IFAIL.
  > N:   if INFO = N + i, for 1 <= i <= N, then the leading
        minor of order i of B is not positive definite.
        The factorization of B could not be completed and
        no eigenvalues or eigenvectors were computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dla_syamv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           DLA_SYAMV computes a matrix-vector product using a symmetric
           indefinite matrix to calculate error bounds.

Function/Subroutine Documentation
   subroutine dla_syamv (integer UPLO, integer N, double precision ALPHA,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) X, integer INCX, double precision BETA, double
       precision, dimension( * ) Y, integer INCY)
       DLA_SYAMV computes a matrix-vector product using a symmetric indefinite
       matrix to calculate error bounds.

Purpose:
   DLA_SYAMV  performs the matrix-vector operation

   y := alpha*abs(A)*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   n by n symmetric matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 UPLO
   UPLO is INTEGER
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as
   follows:

   UPLO = BLAS_UPPER   Only the upper triangular part of A
   is to be referenced.

   UPLO = BLAS_LOWER   Only the lower triangular part of A
   is to be referenced.
```

```
  Unchanged on exit.

N
  N is INTEGER
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is DOUBLE PRECISION .
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is DOUBLE PRECISION array of DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
  Unchanged on exit.

X
  X is DOUBLE PRECISION array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) )
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is DOUBLE PRECISION .
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is DOUBLE PRECISION array, dimension
  ( 1 + ( n - 1 )*abs( INCY ) )
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.
```

```
INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
  Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       double precision function dla_syrcond (UPLO, N, A, LDA, AF, LDAF, IPIV,
           CMODE, C, INFO, WORK, IWORK)
           DLA_SYRCOND estimates the Skeel condition number for a symmetric
           indefinite matrix.
```

```
Function/Subroutine Documentation
   double precision function dla_syrcond (character UPLO, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV,
       integer CMODE, double precision, dimension( * ) C, integer INFO, double
       precision, dimension( * ) WORK, integer, dimension( * ) IWORK)
       DLA_SYRCOND estimates the Skeel condition number for a symmetric
       indefinite matrix.

Purpose:
   DLA_SYRCOND estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by DSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
```

```
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N).
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.
```

      DLA_SYRFSX_EXTENDED improves the computed solution to a system of
      linear equations for symmetric indefinite matrices by performing extra-
      precise iterative refinement and provides error bounds and backward
      error estimates for the solution.

Purpose:
   DLA_SYRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by DSYRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.
```

```
A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by DSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is DOUBLE PRECISION array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by DSYTRS.
  On exit, the improved solution matrix Y.
```

```
LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.
```

```
  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
  almost certainly within a factor of 10 of the true error
  so long as the next entry is greater than the threshold
  sqrt(n) * slamch('Epsilon'). This error bound should only
  be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
  reciprocal condition number.  Compared with the threshold
  sqrt(n) * slamch('Epsilon') to determine if the error
  estimate is "guaranteed". These reciprocal condition
  numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
```

```
  appropriately scaled matrix Z.
  Let Z = S*(A*diag(x)), where x is the solution for the
  current right-hand side and S scales each row of
  A*diag(x) by a power of the radix so all absolute row
  sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.

DY
  DY is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is DOUBLE PRECISION
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
```

```
  for more details.

 DZ_UB
   DZ_UB is DOUBLE PRECISION
   Determines when to start considering componentwise convergence.
   Componentwise convergence is only considered after each component
   of the solution Y is stable, which we definte as the relative
   change in each component being less than DZ_UB. The default value
   is 0.25, requiring the first bit to be stable. See LAWN 165 for
   more details.

 IGNORE_CWISE
   IGNORE_CWISE is LOGICAL
   If .TRUE. then ignore componentwise convergence. Default value
   is .FALSE..

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   < 0:  if INFO = -i, the ith argument to DLA_SYRFSX_EXTENDED had an illegal
         value
```

```
SYNOPSIS
   Functions/Subroutines
       double precision function dla_syrpvgrw (UPLO, N, INFO, A, LDA, AF,
           LDAF, IPIV, WORK)
           DLA_SYRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric indefinite matrix.

Function/Subroutine Documentation
   double precision function dla_syrpvgrw (character*1 UPLO, integer N,
       integer INFO, double precision, dimension( lda, * ) A, integer LDA,
       double precision, dimension( ldaf, * ) AF, integer LDAF, integer,
       dimension( * ) IPIV, double precision, dimension( * ) WORK)
       DLA_SYRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a symmetric indefinite matrix.

Purpose:
   DLA_SYRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 INFO
   INFO is INTEGER
   The value of INFO returned from DSYTRF, .i.e., the pivot in
   column INFO is exactly 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
```

```
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by DSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasyf (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           DLASYF computes a partial factorization of a real symmetric matrix
           using the Bunch-Kaufman diagonal pivoting method.

Function/Subroutine Documentation
   subroutine dlasyf (character UPLO, integer N, integer NB, integer KB,
       double precision, dimension( lda, * ) A, integer LDA, integer,
       dimension( * ) IPIV, double precision, dimension( ldw, * ) W, integer
       LDW, integer INFO)
       DLASYF computes a partial factorization of a real symmetric matrix
       using the Bunch-Kaufman diagonal pivoting method.

Purpose:
   DLASYF computes a partial factorization of a real symmetric matrix A
```

```
  using the Bunch-Kaufman diagonal pivoting method. The partial
  factorization has the form:

      A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
            ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

      A  =  ( L11  0 ) (  D   0  ) ( L11**T L21**T )  if UPLO = 'L'
            ( L21  I ) (  0  A22 ) (  0       I    )

  where the order of D is at most NB. The actual order is returned in
  the argument KB, and is either NB or NB-1, or N if N <= NB.

  DLASYF is an auxiliary routine called by DSYTRF. It uses blocked code
  (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or
  A22 (if UPLO = 'L').

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NB
   NB is INTEGER
   The maximum number of columns of the matrix A that should be
   factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

 KB
   KB is INTEGER
   The number of columns of A that were actually factored.
   KB is either NB-1 or NB, or N if N <= NB.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
   On exit, A contains details of the partial factorization.
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
    Only the last KB elements of IPIV are set.

    If IPIV(k) > 0, then rows and columns k and IPIV(k) were
    interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) = IPIV(k-1) < 0, then rows and columns
    k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
    is a 2-by-2 diagonal block.

  If UPLO = 'L':
    Only the first KB elements of IPIV are set.

    If IPIV(k) > 0, then rows and columns k and IPIV(k) were
    interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) = IPIV(k+1) < 0, then rows and columns
    k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
    is a 2-by-2 diagonal block.

W
  W is DOUBLE PRECISION array, dimension (LDW,NB)

LDW
  LDW is INTEGER
  The leading dimension of the array W.  LDW >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular.

SYNOPSIS
   Functions/Subroutines
       subroutine dlasyf_rook (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           DLASYF_ROOK *> DLASYF_ROOK computes a partial factorization of a
           real symmetric matrix using the bounded Bunch-Kaufman ('rook')
           diagonal pivoting method.

Function/Subroutine Documentation
   subroutine dlasyf_rook (character UPLO, integer N, integer NB, integer KB,
       double precision, dimension( lda, * ) A, integer LDA, integer,
       dimension( * ) IPIV, double precision, dimension( ldw, * ) W, integer
       LDW, integer INFO)
       DLASYF_ROOK *> DLASYF_ROOK computes a partial factorization of a real
       symmetric matrix using the bounded Bunch-Kaufman ('rook') diagonal
       pivoting method.

Purpose:
   DLASYF_ROOK computes a partial factorization of a real symmetric
   matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method. The partial factorization has the form:

       A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
             ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

       A  =  ( L11  0 ) (  D   0  ) ( L11**T L21**T )  if UPLO = 'L'
             ( L21  I ) (  0  A22 ) (  0       I    )

   where the order of D is at most NB. The actual order is returned in
   the argument KB, and is either NB or NB-1, or N if N <= NB.

   DLASYF_ROOK is an auxiliary routine called by DSYTRF_ROOK. It uses
   blocked code (calling Level 3 BLAS) to update the submatrix
   A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Parameters:

 UPLO
```

```
  UPLO is CHARACTER*1
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is stored:
  = 'U':  Upper triangular
  = 'L':  Lower triangular

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NB
  NB is INTEGER
  The maximum number of columns of the matrix A that should be
  factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB
  KB is INTEGER
  The number of columns of A that were actually factored.
  KB is either NB-1 or NB, or N if N <= NB.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     Only the last KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.
```

```
   If UPLO = 'L':
      Only the first KB elements of IPIV are set.

      If IPIV(k) > 0, then rows and columns k and IPIV(k)
      were interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
      columns k and -IPIV(k) were interchanged and rows and
      columns k+1 and -IPIV(k+1) were inerchaged,
      D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

 W
   W is DOUBLE PRECISION array, dimension (LDW,NB)

 LDW
   LDW is INTEGER
   The leading dimension of the array W.  LDW >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular.

SYNOPSIS
   Functions/Subroutines
       subroutine dsycon (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, IWORK,
           INFO)
           DSYCON

Function/Subroutine Documentation
   subroutine dsycon (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double precision
       ANORM, double precision RCOND, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
       DSYCON

Purpose:
   DSYCON estimates the reciprocal of the condition number (in the
   1-norm) of a real symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by DSYTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by DSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

ANORM
  ANORM is DOUBLE PRECISION
  The 1-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsycon_rook (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK,
           IWORK, INFO)
           DSYCON_ROOK

Function/Subroutine Documentation
   subroutine dsycon_rook (character UPLO, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       double precision ANORM, double precision RCOND, double precision,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       DSYCON_ROOK

Purpose:
   DSYCON_ROOK estimates the reciprocal of the condition number (in the
   1-norm) of a real symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by DSYTRF_ROOK.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
```

```
  = 'U':  Upper triangular, form is A = U*D*U**T;
  = 'L':  Lower triangular, form is A = L*D*L**T.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by DSYTRF_ROOK.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF_ROOK.

ANORM
  ANORM is DOUBLE PRECISION
  The 1-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsyconv (UPLO, WAY, N, A, LDA, IPIV, E, INFO)
           DSYCONV

Function/Subroutine Documentation
   subroutine dsyconv (character UPLO, character WAY, integer N, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( * ) E, integer INFO)
       DSYCONV

Purpose:
```

```
  DSYCONV convert A given by TRF into L and D and vice-versa.
  Get Non-diag elements of D (returned in workspace) and
  apply or reverse permutation done in TRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 WAY
   WAY is CHARACTER*1
   = 'C': Convert
   = 'R': Revert

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by DSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by DSYTRF.

 E
   E is DOUBLE PRECISION array, dimension (N)
   E stores the supdiagonal/subdiagonal of the symmetric 1-by-1
   or 2-by-2 block diagonal matrix D in LDLT.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsyequb (UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
           DSYEQUB

Function/Subroutine Documentation
   subroutine dsyequb (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision, dimension( * ) S, double
       precision SCOND, double precision AMAX, double precision, dimension( *
       ) WORK, integer INFO)
       DSYEQUB

Purpose:
   DSYEQUB computes row and column scalings intended to equilibrate a
   symmetric matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 UPLO
   UPLO is CHARACTER*1
```

```
  Specifies whether the details of the factorization are stored
  as an upper or lower triangular matrix.
  = 'U':  Upper triangular, form is A = U*D*U**T;
  = 'L':  Lower triangular, form is A = L*D*L**T.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The N-by-N symmetric matrix whose scaling
  factors are to be computed.  Only the diagonal elements of A
  are referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

S
  S is DOUBLE PRECISION array, dimension (N)
  If INFO = 0, S contains the scale factors for A.

SCOND
  SCOND is DOUBLE PRECISION
  If INFO = 0, S contains the ratio of the smallest S(i) to
  the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
  large nor too small, it is not worth scaling by S.

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the i-th diagonal element is nonpositive.

SYNOPSIS
   Functions/Subroutines
       subroutine dsygs2 (ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
           DSYGS2 reduces a symmetric definite generalized eigenproblem to
           standard form, using the factorization results obtained from spotrf
           (unblocked algorithm).

Function/Subroutine Documentation
   subroutine dsygs2 (integer ITYPE, character UPLO, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       DSYGS2 reduces a symmetric definite generalized eigenproblem to
       standard form, using the factorization results obtained from spotrf
       (unblocked algorithm).

Purpose:
   DSYGS2 reduces a real symmetric-definite generalized eigenproblem
   to standard form.

   If ITYPE = 1, the problem is A*x = lambda*B*x,
   and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)

   If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
   B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T *A*L.

   B must have been previously factorized as U**T *U or L*L**T by DPOTRF.

Parameters:

 ITYPE
   ITYPE is INTEGER
   = 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
   = 2 or 3: compute U*A*U**T or L**T *A*L.
```

```
UPLO
  UPLO is CHARACTER*1
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is stored, and how B has been factorized.
  = 'U':  Upper triangular
  = 'L':  Lower triangular

N
  N is INTEGER
  The order of the matrices A and B.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n by n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n by n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the transformed matrix, stored in the
  same format as A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB,N)
  The triangular factor from the Cholesky factorization of B,
  as returned by DPOTRF.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsygst (ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
           DSYGST

Function/Subroutine Documentation
   subroutine dsygst (integer ITYPE, character UPLO, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       DSYGST

Purpose:
   DSYGST reduces a real symmetric-definite generalized eigenproblem
   to standard form.

   If ITYPE = 1, the problem is A*x = lambda*B*x,
   and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)

   If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
   B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T*A*L.

   B must have been previously factorized as U**T*U or L*L**T by DPOTRF.

Parameters:

 ITYPE
   ITYPE is INTEGER
```

```
  = 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
  = 2 or 3: compute U*A*U**T or L**T*A*L.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored and B is factored as U**T*U;
  = 'L':  Lower triangle of A is stored and B is factored as L*L**T.

N
  N is INTEGER
  The order of the matrices A and B.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the transformed matrix, stored in the
  same format as A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB,N)
  The triangular factor from the Cholesky factorization of B,
  as returned by DPOTRF.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsyrfs (UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
```

```
          LDX, FERR, BERR, WORK, IWORK, INFO)
          DSYRFS

Function/Subroutine Documentation
   subroutine dsyrfs (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV,
       double precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( ldx, * ) X, integer LDX, double precision, dimension( * )
       FERR, double precision, dimension( * ) BERR, double precision,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       DSYRFS

Purpose:
   DSYRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading N-by-N lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
```

```
  The factored form of the matrix A.  AF contains the block
  diagonal matrix D and the multipliers used to obtain the
  factor U or L from the factorization A = U*D*U**T or
  A = L*D*L**T as computed by DSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DSYTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)
```

```
 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.
```

       INFO)
       DSYRFSX

Purpose:
   DSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
           The right hand side B has been changed accordingly.
```

```
N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular
  part of the matrix A, and the strictly lower triangular
  part of A is not referenced.  If UPLO = 'L', the leading
  N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The factored form of the matrix A.  AF contains the block
  diagonal matrix D and the multipliers used to obtain the
  factor U or L from the factorization A = U*D*U**T or A =
  L*D*L**T as computed by DSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

S
  S is DOUBLE PRECISION array, dimension (N)
  The scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
```

```
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
```

```
            ----------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.
```

```
  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension (NPARAMS)
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
```

```
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
     componentwise error is not requested (PARAMS(3) = 0.0) then
     the Jth right-hand side is the first with a normwise error
     bound that is not guaranteed (the smallest J such
     that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
     the Jth right-hand side is the first with either a normwise or
     componentwise error bound that is not guaranteed (the smallest
     J such that either ERR_BNDS_NORM(J,1) = 0.0 or
     ERR_BNDS_COMP(J,1) = 0.0). See the definition of
     ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
     about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine dsytd2 (UPLO, N, A, LDA, D, E, TAU, INFO)
           DSYTD2 reduces a symmetric matrix to real symmetric tridiagonal
           form by an orthogonal similarity transformation (unblocked
           algorithm).

Function/Subroutine Documentation
   subroutine dsytd2 (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision, dimension( * ) TAU,
       integer INFO)
       DSYTD2 reduces a symmetric matrix to real symmetric tridiagonal form by
       an orthogonal similarity transformation (unblocked algorithm).

Purpose:
   DSYTD2 reduces a real symmetric matrix A to symmetric tridiagonal
   form T by an orthogonal similarity transformation: Q**T * A * Q = T.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
   On exit, if UPLO = 'U', the diagonal and first superdiagonal
   of A are overwritten by the corresponding elements of the
   tridiagonal matrix T, and the elements above the first
   superdiagonal, with the array TAU, represent the orthogonal
   matrix Q as a product of elementary reflectors; if UPLO
   = 'L', the diagonal and first subdiagonal of A are over-
   written by the corresponding elements of the tridiagonal
```

```
  matrix T, and the elements below the first subdiagonal, with
  the array TAU, represent the orthogonal matrix Q as a product
  of elementary reflectors. See Further Details.

 LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

 D
  D is DOUBLE PRECISION array, dimension (N)
  The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

 E
  E is DOUBLE PRECISION array, dimension (N-1)
  The off-diagonal elements of the tridiagonal matrix T:
  E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

 TAU
  TAU is DOUBLE PRECISION array, dimension (N-1)
  The scalar factors of the elementary reflectors (see Further Details).

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

  If UPLO = 'U', the matrix Q is represented as a product of elementary
  reflectors

  Q = H(n-1) . . . H(2) H(1).

  Each H(i) has the form

  H(i) = I - tau * v * v**T

  where tau is a real scalar, and v is a real vector with
  v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in
  A(1:i-1,i+1), and tau in TAU(i).

  If UPLO = 'L', the matrix Q is represented as a product of elementary
  reflectors

  Q = H(1) H(2) . . . H(n-1).

  Each H(i) has the form

  H(i) = I - tau * v * v**T
```

```
where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in A(i+2:n,i),
and tau in TAU(i).

The contents of A on exit are illustrated by the following examples
with n = 5:

     if UPLO = 'U':                       if UPLO = 'L':

      (  d   e   v2  v3  v4 )              (  d                  )
      (      d   e   v3  v4 )              (  e   d              )
      (          d   e   v4 )              (  v1  e   d          )
      (              d   e  )              (  v1  v2  e   d      )
      (                  d  )              (  v1  v2  v3  e   d  )

where d and e denote diagonal and off-diagonal elements of T, and vi
denotes an element of the vector defining H(i).

dsytf2.f(3)                          LAPACK                        dsytf2.f(3)

NAME
       dsytf2.f -

SYNOPSIS
   Functions/Subroutines
       subroutine dsytf2 (UPLO, N, A, LDA, IPIV, INFO)
           DSYTF2 computes the factorization of a real symmetric indefinite
           matrix, using the diagonal pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine dsytf2 (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       DSYTF2 computes the factorization of a real symmetric indefinite
       matrix, using the diagonal pivoting method (unblocked algorithm).

Purpose:
   DSYTF2 computes the factorization of a real symmetric matrix A using
   the Bunch-Kaufman diagonal pivoting method:

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
```

```
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is stored:
  = 'U':  Upper triangular
  = 'L':  Lower triangular

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
    If IPIV(k) > 0, then rows and columns k and IPIV(k) were
    interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) = IPIV(k-1) < 0, then rows and columns
    k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
    is a 2-by-2 diagonal block.

  If UPLO = 'L':
    If IPIV(k) > 0, then rows and columns k and IPIV(k) were
    interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) = IPIV(k+1) < 0, then rows and columns
    k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
    is a 2-by-2 diagonal block.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
```

```
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular, and division by zero will occur if it
        is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
             U(k) =    (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine dsytf2_rook (UPLO, N, A, LDA, IPIV, INFO)
           DSYTF2_ROOK computes the factorization of a real symmetric
```

```
          indefinite matrix using the bounded Bunch-Kaufman ('rook') diagonal
          pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine dsytf2_rook (character UPLO, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       integer INFO)
       DSYTF2_ROOK computes the factorization of a real symmetric indefinite
       matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
       method (unblocked algorithm).

Purpose:
   DSYTF2_ROOK computes the factorization of a real symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
```

```
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
      If IPIV(k) > 0, then rows and columns k and IPIV(k)
      were interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
      columns k and -IPIV(k) were interchanged and rows and
      columns k-1 and -IPIV(k-1) were inerchaged,
      D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

   If UPLO = 'L':
      If IPIV(k) > 0, then rows and columns k and IPIV(k)
      were interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
      columns k and -IPIV(k) were interchanged and rows and
      columns k+1 and -IPIV(k+1) were inerchaged,
      D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular, and division by zero will occur if it
        is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                        (   I    v    0   )   k-s
                U(k) =  (   0    I    0   )   s
                        (   0    0    I   )   n-k
                           k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
```

```
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsytrd (UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
           DSYTRD

Function/Subroutine Documentation
   subroutine dsytrd (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision, dimension( * ) TAU,
       double precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DSYTRD

Purpose:
   DSYTRD reduces a real symmetric matrix A to real symmetric
   tridiagonal form T by an orthogonal similarity transformation:
   Q**T * A * Q = T.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
   On exit, if UPLO = 'U', the diagonal and first superdiagonal
   of A are overwritten by the corresponding elements of the
   tridiagonal matrix T, and the elements above the first
   superdiagonal, with the array TAU, represent the orthogonal
   matrix Q as a product of elementary reflectors; if UPLO
```

```
  = 'L', the diagonal and first subdiagonal of A are over-
  written by the corresponding elements of the tridiagonal
  matrix T, and the elements below the first subdiagonal, with
  the array TAU, represent the orthogonal matrix Q as a product
  of elementary reflectors. See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

D
  D is DOUBLE PRECISION array, dimension (N)
  The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E
  E is DOUBLE PRECISION array, dimension (N-1)
  The off-diagonal elements of the tridiagonal matrix T:
  E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU
  TAU is DOUBLE PRECISION array, dimension (N-1)
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= 1.
  For optimum performance LWORK >= N*NB, where NB is the
  optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

  If UPLO = 'U', the matrix Q is represented as a product of elementary
  reflectors

  Q = H(n-1) . . . H(2) H(1).
```

```
Each H(i) has the form

H(i) = I - tau * v * v**T

where tau is a real scalar, and v is a real vector with
v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary
reflectors

Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

H(i) = I - tau * v * v**T

where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in A(i+2:n,i),
and tau in TAU(i).

The contents of A on exit are illustrated by the following examples
with n = 5:

     if UPLO = 'U':                       if UPLO = 'L':

       (  d   e   v2  v3  v4 )              (  d                  )
       (      d   e   v3  v4 )              (  e   d              )
       (          d   e   v4 )              (  v1  e   d          )
       (              d   e  )              (  v1  v2  e   d      )
       (                  d  )              (  v1  v2  v3  e   d  )

where d and e denote diagonal and off-diagonal elements of T, and vi
denotes an element of the vector defining H(i).

SYNOPSIS
   Functions/Subroutines
       subroutine dsytrf (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           DSYTRF

Function/Subroutine Documentation
   subroutine dsytrf (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DSYTRF

Purpose:
   DSYTRF computes the factorization of a real symmetric matrix A using
   the Bunch-Kaufman diagonal pivoting method.  The form of the
   factorization is

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
```

```
  message related to LWORK is issued by XERBLA.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular, and division by zero will occur if it
        is used to solve a system of equations.

Further Details:

  If UPLO = 'U', then A = U*D*U**T, where
     U = P(n)*U(n)* ... *P(k)U(k)* ...,
  i.e., U is a product of terms P(k)*U(k), where k decreases from n to
  1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
  and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
  defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
  that if the diagonal block D(k) is of order s (s = 1 or 2), then

                      (   I    v    0   )   k-s
             U(k) =   (   0    I    0   )   s
                      (   0    0    I   )   n-k
                         k-s   s   n-k

  If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
  If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
  and A(k,k), and v overwrites A(1:k-2,k-1:k).

  If UPLO = 'L', then A = L*D*L**T, where
     L = P(1)*L(1)* ... *P(k)*L(k)* ...,
  i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
  n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
  and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
  defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
  that if the diagonal block D(k) is of order s (s = 1 or 2), then

                      (   I    0     0   )  k-1
             L(k) =   (   0    I     0   )  s
                      (   0    v     I   )  n-k-s+1
                         k-1   s  n-k-s+1

  If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
  If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
  and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsytrf_rook (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           DSYTRF_ROOK

Function/Subroutine Documentation
   subroutine dsytrf_rook (character UPLO, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       double precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DSYTRF_ROOK

Purpose:
   DSYTRF_ROOK computes the factorization of a real symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.
   The form of the factorization is
```

```
   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
      If IPIV(k) > 0, then rows and columns k and IPIV(k)
      were interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
      columns k and -IPIV(k) were interchanged and rows and
      columns k-1 and -IPIV(k-1) were inerchaged,
      D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

   If UPLO = 'L':
```

```
      If IPIV(k) > 0, then rows and columns k and IPIV(k)
      were interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
      columns k and -IPIV(k) were interchanged and rows and
      columns k+1 and -IPIV(k+1) were inerchaged,
      D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

 WORK
   WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)).
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The length of WORK.  LWORK >=1.  For best performance
   LWORK >= N*NB, where NB is the block size returned by ILAENV.

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
         has been completed, but the block diagonal matrix D is
         exactly singular, and division by zero will occur if it
         is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
             U(k) =    (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).
```

```
   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine dsytri (UPLO, N, A, LDA, IPIV, WORK, INFO)
           DSYTRI

Function/Subroutine Documentation
   subroutine dsytri (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double
       precision, dimension( * ) WORK, integer INFO)
       DSYTRI

Purpose:
   DSYTRI computes the inverse of a real symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by DSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by DSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
```

```
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

WORK
  WORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
       inverse could not be computed.
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dsytri2 (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           DSYTRI2

Function/Subroutine Documentation
   subroutine dsytri2 (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double
       precision, dimension( * ) WORK, integer LWORK, integer INFO)
       DSYTRI2

Purpose:
   DSYTRI2 computes the inverse of a DOUBLE PRECISION symmetric
   indefinite matrix A using the factorization A = U*D*U**T
   or A = L*D*L**T computed by DSYTRF. DSYTRI2 sets the
   LEADING DIMENSION of the workspace before calling DSYTRI2X
```

```
   that actually computes the inverse.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the NB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by DSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the NB structure of D
   as determined by DSYTRF.

 WORK
   WORK is DOUBLE PRECISION array, dimension (N+NB+1)*(NB+3)

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.
   WORK is size >= (N+NB+1)*(NB+3)
   If LDWORK = -1, then a workspace query is assumed; the routine
   calculates:
   - the optimal size of the WORK array, returns
   this value as the first entry of the WORK array,
   - and no error message related to LDWORK is issued by XERBLA.

 INFO
```

```
INFO is INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
     inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsytri2x (UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
           DSYTRI2X

Function/Subroutine Documentation
```

```
   subroutine dsytri2x (character UPLO, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       double precision, dimension( n+nb+1,* ) WORK, integer NB, integer INFO)
       DSYTRI2X

Purpose:
   DSYTRI2X computes the inverse of a real symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by DSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the NNB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by DSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the NNB structure of D
   as determined by DSYTRF.

 WORK
   WORK is DOUBLE PRECISION array, dimension (N+NNB+1,NNB+3)

 NB
   NB is INTEGER
   Block size
```

```
 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsytri_rook (UPLO, N, A, LDA, IPIV, WORK, INFO)
           DSYTRI_ROOK

Function/Subroutine Documentation
   subroutine dsytri_rook (character UPLO, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       double precision, dimension( * ) WORK, integer INFO)
       DSYTRI_ROOK

Purpose:
```

```
  DSYTRI_ROOK computes the inverse of a real symmetric
  matrix A using the factorization A = U*D*U**T or A = L*D*L**T
  computed by DSYTRF_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by DSYTRF_ROOK.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by DSYTRF_ROOK.

 WORK
   WORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsytrs (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           DSYTRS

Function/Subroutine Documentation
   subroutine dsytrs (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, integer
       INFO)
       DSYTRS

Purpose:
   DSYTRS solves a system of linear equations A*X = B with a real
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by DSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by DSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by DSYTRF.
```

```
B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dsytrs2 (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
           DSYTRS2

Function/Subroutine Documentation
   subroutine dsytrs2 (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, double
```

```
      precision, dimension( * ) WORK, integer INFO)
      DSYTRS2

Purpose:
   DSYTRS2 solves a system of linear equations A*X = B with a real
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by DSYTRF and converted by DSYCONV.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by DSYTRF.
   Note that A is input / output. This might be counter-intuitive,
   and one may think that A is input only. A is input / output. This
   is because, at the start of the subroutine, we permute A in a
   "better" form and then we permute A back to its original form at the end.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by DSYTRF.

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
```

```
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

 WORK
  WORK is REAL array, dimension (N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dsytrs_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           DSYTRS_ROOK

Function/Subroutine Documentation
   subroutine dsytrs_rook (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, integer
       INFO)
       DSYTRS_ROOK

Purpose:
   DSYTRS_ROOK solves a system of linear equations A*X = B with
   a real symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by DSYTRF_ROOK.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by DSYTRF_ROOK.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by DSYTRF_ROOK.

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dtgsyl (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
           DTGSYL

Function/Subroutine Documentation
   subroutine dtgsyl (character TRANS, integer IJOB, integer M, integer N,
       double precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( ldc, *
       ) C, integer LDC, double precision, dimension( ldd, * ) D, integer LDD,
       double precision, dimension( lde, * ) E, integer LDE, double precision,
       dimension( ldf, * ) F, integer LDF, double precision SCALE, double
       precision DIF, double precision, dimension( * ) WORK, integer LWORK,
       integer, dimension( * ) IWORK, integer INFO)
       DTGSYL

Purpose:
   DTGSYL solves the generalized Sylvester equation:

                   A * R - L * B = scale * C                 (1)
                   D * R - L * E = scale * F

   where R and L are unknown m-by-n matrices, (A, D), (B, E) and
   (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n,
   respectively, with real entries. (A, D) and (B, E) must be in
```

```
  generalized (real) Schur canonical form, i.e. A, B are upper quasi
  triangular and D, E are upper triangular.

  The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output
  scaling factor chosen to avoid overflow.

  In matrix notation (1) is equivalent to solve  Zx = scale b, where
  Z is defined as

                 Z = [ kron(In, A)  -kron(B**T, Im) ]         (2)
                     [ kron(In, D)  -kron(E**T, Im) ].

  Here Ik is the identity matrix of size k and X**T is the transpose of
  X. kron(X, Y) is the Kronecker product between the matrices X and Y.

  If TRANS = 'T', DTGSYL solves the transposed system Z**T*y = scale*b,
  which is equivalent to solve for R and L in

                  A**T * R + D**T * L = scale * C           (3)
                  R * B**T + L * E**T = scale * -F

  This case (TRANS = 'T') is used to compute an one-norm-based estimate
  of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D)
  and (B,E), using DLACON.

  If IJOB >= 1, DTGSYL computes a Frobenius norm-based estimate
  of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the
  reciprocal of the smallest singular value of Z. See [1-2] for more
  information.

  This is a level 3 BLAS algorithm.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N', solve the generalized Sylvester equation (1).
   = 'T', solve the 'transposed' system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   =0: solve (1) only.
   =1: The functionality of 0 and 3.
   =2: The functionality of 0 and 4.
   =3: Only an estimate of Dif[(A,D), (B,E)] is computed.
       (look ahead strategy IJOB  = 1 is used).
   =4: Only an estimate of Dif[(A,D), (B,E)] is computed.
       ( DGECON on sub-systems is used ).
   Not referenced if TRANS = 'T'.
```

```
M
  M is INTEGER
  The order of the matrices A and D, and the row dimension of
  the matrices C, F, R and L.

N
  N is INTEGER
  The order of the matrices B and E, and the column dimension
  of the matrices C, F, R and L.

A
  A is DOUBLE PRECISION array, dimension (LDA, M)
  The upper quasi triangular matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1, M).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  The upper quasi triangular matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1, N).

C
  C is DOUBLE PRECISION array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, C has been overwritten by
  the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R,
  the solution achieved during the computation of the Dif-estimate.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1, M).

D
  D is DOUBLE PRECISION array, dimension (LDD, M)
  The upper triangular matrix D.

LDD
  LDD is INTEGER
  The leading dimension of the array D. LDD >= max(1, M).

E
  E is DOUBLE PRECISION array, dimension (LDE, N)
  The upper triangular matrix E.
```

```
LDE
  LDE is INTEGER
  The leading dimension of the array E. LDE >= max(1, N).

F
  F is DOUBLE PRECISION array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, F has been overwritten by
  the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L,
  the solution achieved during the computation of the Dif-estimate.

LDF
  LDF is INTEGER
  The leading dimension of the array F. LDF >= max(1, M).

DIF
  DIF is DOUBLE PRECISION
  On exit DIF is the reciprocal of a lower bound of the
  reciprocal of the Dif-function, i.e. DIF is an upper bound of
  Dif[(A,D), (B,E)] = sigma_min(Z), where Z as in (2).
  IF IJOB = 0 or TRANS = 'T', DIF is not touched.

SCALE
  SCALE is DOUBLE PRECISION
  On exit SCALE is the scaling factor in (1) or (3).
  If 0 < SCALE < 1, C and F hold the solutions R and L, resp.,
  to a slightly perturbed system but the input matrices A, B, D
  and E have not been changed. If SCALE = 0, C and F hold the
  solutions R and L, respectively, to the homogeneous system
  with C = F = 0. Normally, SCALE = 1.

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK > = 1.
  If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (M+N+6)
```

```
 INFO
   INFO is INTEGER
   =0: successful exit
   <0: If INFO = -i, the i-th argument had an illegal value.
   >0: (A, D) and (B, E) have common or close eigenvalues.

SYNOPSIS
   Functions/Subroutines
       subroutine dtrsyl (TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
           SCALE, INFO)
```

```
          DTRSYL

Function/Subroutine Documentation
   subroutine dtrsyl (character TRANA, character TRANB, integer ISGN, integer
       M, integer N, double precision, dimension( lda, * ) A, integer LDA,
       double precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( ldc, * ) C, integer LDC, double precision SCALE, integer
       INFO)
       DTRSYL

Purpose:
   DTRSYL solves the real Sylvester matrix equation:

      op(A)*X + X*op(B) = scale*C or
      op(A)*X - X*op(B) = scale*C,

   where op(A) = A or A**T, and  A and B are both upper quasi-
   triangular. A is M-by-M and B is N-by-N; the right hand side C and
   the solution X are M-by-N; and scale is an output scale factor, set
   <= 1 to avoid overflow in X.

   A and B must be in Schur canonical form (as returned by DHSEQR), that
   is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks;
   each 2-by-2 diagonal block has its diagonal elements equal and its
   off-diagonal elements of opposite sign.

Parameters:

 TRANA
   TRANA is CHARACTER*1
   Specifies the option op(A):
   = 'N': op(A) = A    (No transpose)
   = 'T': op(A) = A**T (Transpose)
   = 'C': op(A) = A**H (Conjugate transpose = Transpose)

 TRANB
   TRANB is CHARACTER*1
   Specifies the option op(B):
   = 'N': op(B) = B    (No transpose)
   = 'T': op(B) = B**T (Transpose)
   = 'C': op(B) = B**H (Conjugate transpose = Transpose)

 ISGN
   ISGN is INTEGER
   Specifies the sign in the equation:
   = +1: solve op(A)*X + X*op(B) = scale*C
   = -1: solve op(A)*X - X*op(B) = scale*C

 M
   M is INTEGER
```

```
  The order of the matrix A, and the number of rows in the
  matrices X and C. M >= 0.

N
  N is INTEGER
  The order of the matrix B, and the number of columns in the
  matrices X and C. N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,M)
  The upper quasi-triangular matrix A, in Schur canonical form.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

B
  B is DOUBLE PRECISION array, dimension (LDB,N)
  The upper quasi-triangular matrix B, in Schur canonical form.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

C
  C is DOUBLE PRECISION array, dimension (LDC,N)
  On entry, the M-by-N right hand side matrix C.
  On exit, C is overwritten by the solution matrix X.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M)

SCALE
  SCALE is DOUBLE PRECISION
  The scale factor, scale, set <= 1 to avoid overflow in X.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1: A and B have common or very close eigenvalues; perturbed
       values were used to solve the equation (but the matrices
       A and B are unchanged).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sla_syamv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           SLA_SYAMV computes a matrix-vector product using a symmetric
           indefinite matrix to calculate error bounds.

Function/Subroutine Documentation
   subroutine sla_syamv (integer UPLO, integer N, real ALPHA, real, dimension(
       lda, * ) A, integer LDA, real, dimension( * ) X, integer INCX, real
       BETA, real, dimension( * ) Y, integer INCY)
       SLA_SYAMV computes a matrix-vector product using a symmetric indefinite
       matrix to calculate error bounds.

Purpose:
   SLA_SYAMV  performs the matrix-vector operation

   y := alpha*abs(A)*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   n by n symmetric matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 UPLO
   UPLO is INTEGER
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as
   follows:

   UPLO = BLAS_UPPER   Only the upper triangular part of A is to be referenced.
   UPLO = BLAS_LOWER   Only the lower triangular part of A is to be referenced.

 Unchanged on exit.

 N
   N is INTEGER
```

```
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is REAL .
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is REAL array of DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
  Unchanged on exit.

X
  X is REAL array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) )
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is REAL .
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is REAL array, dimension
  ( 1 + ( n - 1 )*abs( INCY ) )
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
```

```
Unchanged on exit.
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       real function sla_syrcond (UPLO, N, A, LDA, AF, LDAF, IPIV, CMODE, C,
           INFO, WORK, IWORK)
           SLA_SYRCOND estimates the Skeel condition number for a symmetric
           indefinite matrix.

Function/Subroutine Documentation
   real function sla_syrcond (character UPLO, integer N, real, dimension( lda,
       * ) A, integer LDA, real, dimension( ldaf, * ) AF, integer LDAF,
       integer, dimension( * ) IPIV, integer CMODE, real, dimension( * ) C,
       integer INFO, real, dimension( * ) WORK, integer, dimension( * ) IWORK)
       SLA_SYRCOND estimates the Skeel condition number for a symmetric
       indefinite matrix.

Purpose:
```

```
  SLA_SYRCOND estimates the Skeel condition number of  op(A) * op2(C)
  where op2 is determined by CMODE as follows
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)
  The Skeel condition number cond(A) = norminf( |inv(A)||A| )
  is computed by computing scaling factors R such that
  diag(R)*A*op2(C) is row equilibrated and computing the standard
  infinity-norm condition number.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF.

 CMODE
   CMODE is INTEGER
   Determines op2(C) in the formula op(A) * op2(C) as follows:
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
```

```
C
  C is REAL array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is REAL array, dimension (3*N).
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.
```

       SLA_SYRFSX_EXTENDED improves the computed solution to a system of
       linear equations for symmetric indefinite matrices by performing extra-
       precise iterative refinement and provides error bounds and backward
       error estimates for the solution.

Purpose:
```

```
  SLA_SYRFSX_EXTENDED improves the computed solution to a system of
  linear equations by performing extra-precise iterative refinement
  and provides error bounds and backward error estimates for the solution.
  This subroutine is called by SSYRFSX to perform iterative refinement.
  In addition to normwise error bound, the code provides maximum
  componentwise error bound if possible. See comments for ERR_BNDS_NORM
  and ERR_BNDS_COMP for details of the error bounds. Note that this
  subroutine is only resonsible for setting the second fields of
  ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF.

 LDAF
```

```
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by SSYTRF.

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is REAL array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by SSYTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS
```

```
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
```

```
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
              abs(XTRUE(j,i) - X(j,i))
         max_j ----------------------
                    abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is REAL array, dimension (N)
  Workspace to hold the intermediate residual.
```

```
AYB
  AYB is REAL array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.

DY
  DY is REAL array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is REAL array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
```

```
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

 INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to SLA_SYRFSX_EXTENDED had an illegal
  value

SYNOPSIS
   Functions/Subroutines
       real function sla_syrpvgrw (UPLO, N, INFO, A, LDA, AF, LDAF, IPIV,
           WORK)
           SLA_SYRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric indefinite matrix.

Function/Subroutine Documentation
   real function sla_syrpvgrw (character*1 UPLO, integer N, integer INFO,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * )
       AF, integer LDAF, integer, dimension( * ) IPIV, real, dimension( * )
       WORK)
```

```
      SLA_SYRPVGRW computes the reciprocal pivot growth factor
      norm(A)/norm(U) for a symmetric indefinite matrix.

Purpose:
   SLA_SYRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 INFO
   INFO is INTEGER
   The value of INFO returned from SSYTRF, .i.e., the pivot in
   column INFO is exactly 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF.

 WORK
```

```
WORK is REAL array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasyf (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           SLASYF computes a partial factorization of a real symmetric matrix
           using the Bunch-Kaufman diagonal pivoting method.

Function/Subroutine Documentation
   subroutine slasyf (character UPLO, integer N, integer NB, integer KB, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( ldw, * ) W, integer LDW, integer INFO)
       SLASYF computes a partial factorization of a real symmetric matrix
       using the Bunch-Kaufman diagonal pivoting method.

Purpose:
   SLASYF computes a partial factorization of a real symmetric matrix A
   using the Bunch-Kaufman diagonal pivoting method. The partial
   factorization has the form:

       A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
             ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

       A  =  ( L11  0 ) (  D   0  ) ( L11**T L21**T )  if UPLO = 'L'
             ( L21  I ) (  0  A22 ) (  0       I    )

   where the order of D is at most NB. The actual order is returned in
   the argument KB, and is either NB or NB-1, or N if N <= NB.

   SLASYF is an auxiliary routine called by SSYTRF. It uses blocked code
   (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or
   A22 (if UPLO = 'L').

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is stored:
  = 'U':  Upper triangular
  = 'L':  Lower triangular

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NB
  NB is INTEGER
  The maximum number of columns of the matrix A that should be
  factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB
  KB is INTEGER
  The number of columns of A that were actually factored.
  KB is either NB-1 or NB, or N if N <= NB.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     Only the last KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k-1) < 0, then rows and columns
     k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
     is a 2-by-2 diagonal block.
```

```
  If UPLO = 'L':
     Only the first KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k+1) < 0, then rows and columns
     k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
     is a 2-by-2 diagonal block.

W
  W is REAL array, dimension (LDW,NB)

LDW
  LDW is INTEGER
  The leading dimension of the array W.  LDW >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular.

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine slasyf_rook (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           SLASYF_ROOK computes a partial factorization of a real symmetric
           matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
           method.

Function/Subroutine Documentation
   subroutine slasyf_rook (character UPLO, integer N, integer NB, integer KB,
       real, dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       real, dimension( ldw, * ) W, integer LDW, integer INFO)
       SLASYF_ROOK computes a partial factorization of a real symmetric matrix
       using the bounded Bunch-Kaufman ('rook') diagonal pivoting method.

Purpose:
   SLASYF_ROOK computes a partial factorization of a real symmetric
   matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method. The partial factorization has the form:

       A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
             ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

       A  =  ( L11  0 ) (  D   0  ) ( L11**T L21**T )  if UPLO = 'L'
             ( L21  I ) (  0  A22 ) (  0       I    )

   where the order of D is at most NB. The actual order is returned in
   the argument KB, and is either NB or NB-1, or N if N <= NB.

   SLASYF_ROOK is an auxiliary routine called by SSYTRF_ROOK. It uses
   blocked code (calling Level 3 BLAS) to update the submatrix
   A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NB
   NB is INTEGER
   The maximum number of columns of the matrix A that should be
   factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

 KB
```

```
  KB is INTEGER
  The number of columns of A that were actually factored.
  KB is either NB-1 or NB, or N if N <= NB.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     Only the last KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
     Only the first KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W
  W is REAL array, dimension (LDW,NB)

LDW
  LDW is INTEGER
```

```
  The leading dimension of the array W.  LDW >= max(1,N).

 INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular.

SYNOPSIS
   Functions/Subroutines
       subroutine ssycon (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, IWORK,
           INFO)
           SSYCON

Function/Subroutine Documentation
   subroutine ssycon (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, real ANORM, real RCOND,
```

```
      real, dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
      SSYCON

Purpose:
   SSYCON estimates the reciprocal of the condition number (in the
   1-norm) of a real symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF.

 ANORM
   ANORM is REAL
   The 1-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
   estimate of the 1-norm of inv(A) computed in this routine.

 WORK
   WORK is REAL array, dimension (2*N)
```

```
 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssycon_rook (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK,
           IWORK, INFO)
           SSYCON_ROOK

Function/Subroutine Documentation
   subroutine ssycon_rook (character UPLO, integer N, real, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, real ANORM, real RCOND,
       real, dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SSYCON_ROOK

Purpose:
   SSYCON_ROOK estimates the reciprocal of the condition number (in the
   1-norm) of a real symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by SSYTRF_ROOK.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF_ROOK.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
```

```
  Details of the interchanges and the block structure of D
  as determined by SSYTRF_ROOK.

ANORM
  ANORM is REAL
  The 1-norm of the original matrix A.

RCOND
  RCOND is REAL
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is REAL array, dimension (2*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine ssyconv (UPLO, WAY, N, A, LDA, IPIV, E, INFO)
           SSYCONV

Function/Subroutine Documentation
   subroutine ssyconv (character UPLO, character WAY, integer N, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( * ) E, integer INFO)
       SSYCONV

Purpose:
   SSYCONV convert A given by TRF into L and D and vice-versa.
   Get Non-diag elements of D (returned in workspace) and
   apply or reverse permutation done in TRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 WAY
   WAY is CHARACTER*1
   = 'C': Convert
   = 'R': Revert
```

```
N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by SSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by SSYTRF.

E
  E is REAL array, dimension (N)
  E stores the supdiagonal/subdiagonal of the symmetric 1-by-1
  or 2-by-2 block diagonal matrix D in LDLT.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyequb (UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
           SSYEQUB

Function/Subroutine Documentation
   subroutine ssyequb (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) S, real SCOND, real AMAX, real,
       dimension( * ) WORK, integer INFO)
       SSYEQUB

Purpose:
   SSYEQUB computes row and column scalings intended to equilibrate a
   symmetric matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The N-by-N symmetric matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
    are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
 S
   S is REAL array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is REAL
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
   AMAX is REAL
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix
   should be scaled.

 WORK
   WORK is REAL array, dimension (3*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssygs2 (ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
           SSYGS2 reduces a symmetric definite generalized eigenproblem to
           standard form, using the factorization results obtained from spotrf
```

```
          (unblocked algorithm).

Function/Subroutine Documentation
   subroutine ssygs2 (integer ITYPE, character UPLO, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       SSYGS2 reduces a symmetric definite generalized eigenproblem to
       standard form, using the factorization results obtained from spotrf
       (unblocked algorithm).

Purpose:
   SSYGS2 reduces a real symmetric-definite generalized eigenproblem
   to standard form.

   If ITYPE = 1, the problem is A*x = lambda*B*x,
   and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)

   If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
   B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T *A*L.

   B must have been previously factorized as U**T *U or L*L**T by SPOTRF.

Parameters:

 ITYPE
   ITYPE is INTEGER
   = 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
   = 2 or 3: compute U*A*U**T or L**T *A*L.

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored, and how B has been factorized.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n by n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
```

```
  On exit, if INFO = 0, the transformed matrix, stored in the
  same format as A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB,N)
  The triangular factor from the Cholesky factorization of B,
  as returned by SPOTRF.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssygst (ITYPE, UPLO, N, A, LDA, B, LDB, INFO)
           SSYGST

Function/Subroutine Documentation
   subroutine ssygst (integer ITYPE, character UPLO, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       SSYGST

Purpose:
   SSYGST reduces a real symmetric-definite generalized eigenproblem
   to standard form.

   If ITYPE = 1, the problem is A*x = lambda*B*x,
   and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)

   If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
   B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T*A*L.

   B must have been previously factorized as U**T*U or L*L**T by SPOTRF.

Parameters:

 ITYPE
   ITYPE is INTEGER
   = 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
   = 2 or 3: compute U*A*U**T or L**T*A*L.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored and B is factored as U**T*U;
   = 'L':  Lower triangle of A is stored and B is factored as L*L**T.

 N
   N is INTEGER
   The order of the matrices A and B.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
```

```
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the transformed matrix, stored in the
  same format as A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB,N)
  The triangular factor from the Cholesky factorization of B,
  as returned by SPOTRF.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssyrfs (UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, IWORK, INFO)
           SSYRFS

Function/Subroutine Documentation
   subroutine ssyrfs (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * ) AF,
       integer LDAF, integer, dimension( * ) IPIV, real, dimension( ldb, * )
       B, integer LDB, real, dimension( ldx, * ) X, integer LDX, real,
       dimension( * ) FERR, real, dimension( * ) BERR, real, dimension( * )
       WORK, integer, dimension( * ) IWORK, integer INFO)
       SSYRFS

Purpose:
   SSYRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
```

```
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is REAL array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is REAL array, dimension (LDAF,N)
  The factored form of the matrix A.  AF contains the block
  diagonal matrix D and the multipliers used to obtain the
  factor U or L from the factorization A = U*D*U**T or
  A = L*D*L**T as computed by SSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by SSYTRF.

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

```
 X
   X is REAL array, dimension (LDX,NRHS)
   On entry, the solution matrix X, as computed by SSYTRS.
   On exit, the improved solution matrix X.

 LDX
   LDX is INTEGER
   The leading dimension of the array X.  LDX >= max(1,N).

 FERR
   FERR is REAL array, dimension (NRHS)
   The estimated forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is REAL array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is REAL array, dimension (3*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.

       nrhs, * ) ERR_BNDS_COMP, integer NPARAMS, real, dimension( * ) PARAMS,
       real, dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SSYRFSX

Purpose:
   SSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.
```

```
   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
   The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular
   part of the matrix A, and the strictly lower triangular
   part of A is not referenced.  If UPLO = 'L', the leading
   N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The factored form of the matrix A.  AF contains the block
   diagonal matrix D and the multipliers used to obtain the
```

```
  factor U or L from the factorization A = U*D*U**T or A =
  L*D*L**T as computed by SSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by SSYTRF.

S
  S is REAL array, dimension (N)
  The scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
```

```
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
         max_j (abs(XTRUE(j,i) - X(j,i)))
          ------------------------------
                max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
```

```
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*A, where S scales each row by a power of the
      radix so all absolute row sums of Z are approximately 1.

 ERR_BNDS_COMP
   ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
   For each right-hand side, this array contains information about
   various error bounds and condition numbers corresponding to the
   componentwise relative error, which is defined as follows:

   Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

   The array is indexed by the right-hand side i (on which the
   componentwise relative error depends), and the type of error
   information as described below. There currently are up to three
   pieces of information returned for each right-hand side. If
   componentwise accuracy is not requested (PARAMS(3) = 0.0), then
   ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
   the first (:,N_ERR_BNDS) entries are returned.

   The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
   right-hand side.

   The second index in ERR_BNDS_COMP(:,err) contains the following
   three fields:

   err = 1 "Trust/don't trust" boolean. Trust the answer if the
      reciprocal condition number is less than the threshold
      sqrt(n) * slamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
      sqrt(n) * slamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * slamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*(A*diag(x)), where x is the solution for the
      current right-hand side and S scales each row of
      A*diag(x) by a power of the radix so all absolute row
      sums of Z are approximately 1.
```

```
NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be
              trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
```

```
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine ssytd2 (UPLO, N, A, LDA, D, E, TAU, INFO)
           SSYTD2 reduces a symmetric matrix to real symmetric tridiagonal
           form by an orthogonal similarity transformation (unblocked
           algorithm).

Function/Subroutine Documentation
   subroutine ssytd2 (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) D, real, dimension( * ) E, real,
       dimension( * ) TAU, integer INFO)
       SSYTD2 reduces a symmetric matrix to real symmetric tridiagonal form by
       an orthogonal similarity transformation (unblocked algorithm).

Purpose:
   SSYTD2 reduces a real symmetric matrix A to symmetric tridiagonal
```

```
  form T by an orthogonal similarity transformation: Q**T * A * Q = T.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
   On exit, if UPLO = 'U', the diagonal and first superdiagonal
   of A are overwritten by the corresponding elements of the
   tridiagonal matrix T, and the elements above the first
   superdiagonal, with the array TAU, represent the orthogonal
   matrix Q as a product of elementary reflectors; if UPLO
   = 'L', the diagonal and first subdiagonal of A are over-
   written by the corresponding elements of the tridiagonal
   matrix T, and the elements below the first subdiagonal, with
   the array TAU, represent the orthogonal matrix Q as a product
   of elementary reflectors. See Further Details.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 D
   D is REAL array, dimension (N)
   The diagonal elements of the tridiagonal matrix T:
   D(i) = A(i,i).

 E
   E is REAL array, dimension (N-1)
   The off-diagonal elements of the tridiagonal matrix T:
   E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

 TAU
```

```
   TAU is REAL array, dimension (N-1)
   The scalar factors of the elementary reflectors (see Further Details).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value.

Further Details:

   If UPLO = 'U', the matrix Q is represented as a product of elementary
   reflectors

               Q = H(n-1) . . . H(2) H(1).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in
   A(1:i-1,i+1), and tau in TAU(i).

   If UPLO = 'L', the matrix Q is represented as a product of elementary
   reflectors

               Q = H(1) H(2) . . . H(n-1).

   Each H(i) has the form

               H(i) = I - tau * v * v**T

   where tau is a real scalar, and v is a real vector with
   v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in A(i+2:n,i),
   and tau in TAU(i).

   The contents of A on exit are illustrated by the following examples
   with n = 5:

        if UPLO = 'U':                        if UPLO = 'L':

          (  d   e   v2  v3  v4 )               (  d                  )
          (      d   e   v3  v4 )               (  e   d              )
          (          d   e   v4 )               (  v1  e   d          )
          (              d   e  )               (  v1  v2  e   d      )
          (                  d  )               (  v1  v2  v3  e   d  )

   where d and e denote diagonal and off-diagonal elements of T, and vi
   denotes an element of the vector defining H(i).

SYNOPSIS
   Functions/Subroutines
       subroutine ssytf2 (UPLO, N, A, LDA, IPIV, INFO)
           SSYTF2 computes the factorization of a real symmetric indefinite
           matrix, using the diagonal pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine ssytf2 (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, integer INFO)
       SSYTF2 computes the factorization of a real symmetric indefinite
       matrix, using the diagonal pivoting method (unblocked algorithm).

Purpose:
   SSYTF2 computes the factorization of a real symmetric matrix A using
   the Bunch-Kaufman diagonal pivoting method:

               A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
```

```
   to obtain the factor U or L (see below for further details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
      If IPIV(k) > 0, then rows and columns k and IPIV(k) were
      interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) = IPIV(k-1) < 0, then rows and columns
      k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
      is a 2-by-2 diagonal block.

   If UPLO = 'L':
      If IPIV(k) > 0, then rows and columns k and IPIV(k) were
      interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) = IPIV(k+1) < 0, then rows and columns
      k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
      is a 2-by-2 diagonal block.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                         (   I    v    0   )   k-s
                U(k) =   (   0    I    0   )   s
                         (   0    0    I   )   n-k
                            k-s   s   n-k
```

```
If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L**T, where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
that if the diagonal block D(k) is of order s (s = 1 or 2), then

                     (   I    0     0   )  k-1
             L(k) =  (   0    I     0   )  s
                     (   0    v     I   )  n-k-s+1
                        k-1   s  n-k-s+1

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine ssytf2_rook (UPLO, N, A, LDA, IPIV, INFO)
           SSYTF2_ROOK computes the factorization of a real symmetric
           indefinite matrix using the bounded Bunch-Kaufman ('rook') diagonal
           pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine ssytf2_rook (character UPLO, integer N, real, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       SSYTF2_ROOK computes the factorization of a real symmetric indefinite
       matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
       method (unblocked algorithm).

Purpose:
   SSYTF2_ROOK computes the factorization of a real symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
```

```
  The order of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
  > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
     has been completed, but the block diagonal matrix D is
     exactly singular, and division by zero will occur if it
     is used to solve a system of equations.
```

```
Further Details:
   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
             U(k) =    (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine ssytrd (UPLO, N, A, LDA, D, E, TAU, WORK, LWORK, INFO)
           SSYTRD

Function/Subroutine Documentation
   subroutine ssytrd (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) D, real, dimension( * ) E, real,
       dimension( * ) TAU, real, dimension( * ) WORK, integer LWORK, integer
       INFO)
       SSYTRD

Purpose:
   SSYTRD reduces a real symmetric matrix A to real symmetric
   tridiagonal form T by an orthogonal similarity transformation:
   Q**T * A * Q = T.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
   On exit, if UPLO = 'U', the diagonal and first superdiagonal
   of A are overwritten by the corresponding elements of the
   tridiagonal matrix T, and the elements above the first
   superdiagonal, with the array TAU, represent the orthogonal
   matrix Q as a product of elementary reflectors; if UPLO
   = 'L', the diagonal and first subdiagonal of A are over-
```

```
  written by the corresponding elements of the tridiagonal
  matrix T, and the elements below the first subdiagonal, with
  the array TAU, represent the orthogonal matrix Q as a product
  of elementary reflectors. See Further Details.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

D
  D is REAL array, dimension (N)
  The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E
  E is REAL array, dimension (N-1)
  The off-diagonal elements of the tridiagonal matrix T:
  E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU
  TAU is REAL array, dimension (N-1)
  The scalar factors of the elementary reflectors (see Further Details).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.  LWORK >= 1.
  For optimum performance LWORK >= N*NB, where NB is the
  optimal blocksize.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

Further Details:

  If UPLO = 'U', the matrix Q is represented as a product of elementary
  reflectors

              Q = H(n-1) . . . H(2) H(1).

  Each H(i) has the form
```

```
             H(i) = I - tau * v * v**T

where tau is a real scalar, and v is a real vector with
v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary
reflectors

             Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

             H(i) = I - tau * v * v**T

where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in A(i+2:n,i),
and tau in TAU(i).

The contents of A on exit are illustrated by the following examples
with n = 5:

     if UPLO = 'U':                       if UPLO = 'L':

       (  d   e   v2  v3  v4 )              (  d                  )
       (      d   e   v3  v4 )              (  e   d              )
       (          d   e   v4 )              (  v1  e   d          )

SYNOPSIS
   Functions/Subroutines
       subroutine ssytrf (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           SSYTRF

Function/Subroutine Documentation
   subroutine ssytrf (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
       SSYTRF

Purpose:
   SSYTRF computes the factorization of a real symmetric matrix A using
   the Bunch-Kaufman diagonal pivoting method.  The form of the
   factorization is

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
```

```
  message related to LWORK is issued by XERBLA.

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
     has been completed, but the block diagonal matrix D is
     exactly singular, and division by zero will occur if it
     is used to solve a system of equations.

Further Details:

  If UPLO = 'U', then A = U*D*U**T, where
     U = P(n)*U(n)* ... *P(k)U(k)* ...,
  i.e., U is a product of terms P(k)*U(k), where k decreases from n to
  1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
  and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
  defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
  that if the diagonal block D(k) is of order s (s = 1 or 2), then

                      (   I    v    0   )   k-s
             U(k) =   (   0    I    0   )   s
                      (   0    0    I   )   n-k
                         k-s   s   n-k

  If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
  If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
  and A(k,k), and v overwrites A(1:k-2,k-1:k).

  If UPLO = 'L', then A = L*D*L**T, where
     L = P(1)*L(1)* ... *P(k)*L(k)* ...,
  i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
  n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
  and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
  defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
  that if the diagonal block D(k) is of order s (s = 1 or 2), then

                      (   I    0     0   )  k-1
             L(k) =   (   0    I     0   )  s
                      (   0    v     I   )  n-k-s+1
                         k-1   s  n-k-s+1

  If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
  If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
  and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssytrf_rook (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           SSYTRF_ROOK

Function/Subroutine Documentation
   subroutine ssytrf_rook (character UPLO, integer N, real, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, real, dimension( * )
       WORK, integer LWORK, integer INFO)
       SSYTRF_ROOK

Purpose:
   SSYTRF_ROOK computes the factorization of a real symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.
   The form of the factorization is
```

```
   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
      If IPIV(k) > 0, then rows and columns k and IPIV(k)
      were interchanged and D(k,k) is a 1-by-1 diagonal block.

      If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
      columns k and -IPIV(k) were interchanged and rows and
      columns k-1 and -IPIV(k-1) were inerchaged,
      D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

   If UPLO = 'L':
```

```
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK)).
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
     has been completed, but the block diagonal matrix D is
     exactly singular, and division by zero will occur if it
     is used to solve a system of equations.

Further Details:

  If UPLO = 'U', then A = U*D*U**T, where
     U = P(n)*U(n)* ... *P(k)U(k)* ...,
  i.e., U is a product of terms P(k)*U(k), where k decreases from n to
  1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
  and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
  defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
  that if the diagonal block D(k) is of order s (s = 1 or 2), then

                     (   I    v    0   )   k-s
             U(k) =  (   0    I    0   )   s
                     (   0    0    I   )   n-k
                        k-s   s   n-k

  If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
  If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
  and A(k,k), and v overwrites A(1:k-2,k-1:k).
```

```
If UPLO = 'L', then A = L*D*L**T, where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
that if the diagonal block D(k) is of order s (s = 1 or 2), then

                     (   I    0     0   )  k-1
             L(k) =  (   0    I     0   )  s
                     (   0    v     I   )  n-k-s+1
                        k-1   s  n-k-s+1

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssytri (UPLO, N, A, LDA, IPIV, WORK, INFO)
           SSYTRI

Function/Subroutine Documentation
   subroutine ssytri (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, real, dimension( * ) WORK,
       integer INFO)
       SSYTRI

Purpose:
   SSYTRI computes the inverse of a real symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by SSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF.

 WORK
   WORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

ssytri2 examples
======================================================================

======================================================================
Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine ssytri2 (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           SSYTRI2

Function/Subroutine Documentation
   subroutine ssytri2 (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer, dimension( * ) IPIV, real, dimension( * ) WORK,
       integer LWORK, integer INFO)
       SSYTRI2

Purpose:
   SSYTRI2 computes the inverse of a REAL symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by
   SSYTRF. SSYTRI2 sets the LEADING DIMENSION of the workspace
   before calling SSYTRI2X that actually computes the inverse.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the NB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by SSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the NB structure of D
   as determined by SSYTRF.

 WORK
   WORK is REAL array, dimension (N+NB+1)*(NB+3)

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.
   WORK is size >= (N+NB+1)*(NB+3)
   If LDWORK = -1, then a workspace query is assumed; the routine
   calculates:
   - the optimal size of the WORK array, returns
   this value as the first entry of the WORK array,
   - and no error message related to LDWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
   = 0: successful exit
```

```
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
     inverse could not be computed.
```

Man Page Details
====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine ssytri2x (UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
           SSYTRI2X

Function/Subroutine Documentation
   subroutine ssytri2x (character UPLO, integer N, real, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, real, dimension( n+nb+1,*
       ) WORK, integer NB, integer INFO)
       SSYTRI2X

Purpose:
```

```
  SSYTRI2X computes the inverse of a real symmetric indefinite matrix
  A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the NNB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by SSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the NNB structure of D
   as determined by SSYTRF.

 WORK
   WORK is REAL array, dimension (N+NNB+1,NNB+3)

 NB
   NB is INTEGER
   Block size

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.

SYNOPSIS
   Functions/Subroutines
       subroutine ssytri_rook (UPLO, N, A, LDA, IPIV, WORK, INFO)
           SSYTRI_ROOK

Function/Subroutine Documentation
   subroutine ssytri_rook (character UPLO, integer N, real, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, real, dimension( * )
       WORK, integer INFO)
       SSYTRI_ROOK

Purpose:
   SSYTRI_ROOK computes the inverse of a real symmetric
   matrix A using the factorization A = U*D*U**T or A = L*D*L**T
   computed by SSYTRF_ROOK.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by SSYTRF_ROOK.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF_ROOK.

 WORK
   WORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssytrs (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           SSYTRS

Function/Subroutine Documentation
   subroutine ssytrs (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       SSYTRS

Purpose:
   SSYTRS solves a system of linear equations A*X = B with a real
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by SSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF.
```

```
B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine ssytrs2 (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
           SSYTRS2

Function/Subroutine Documentation
   subroutine ssytrs2 (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, real, dimension( * ) WORK, integer
```

```
      INFO)
      SSYTRS2

Purpose:
   SSYTRS2 solves a system of linear equations A*X = B with a real
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by SSYTRF and converted by SSYCONV.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF.
   Note that A is input / output. This might be counter-intuitive,
   and one may think that A is input only. A is input / output. This
   is because, at the start of the subroutine, we permute A in a
   "better" form and then we permute A back to its original form at
   the end.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF.

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine ssytrs_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           SSYTRS_ROOK

Function/Subroutine Documentation
   subroutine ssytrs_rook (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       SSYTRS_ROOK

Purpose:
   SSYTRS_ROOK solves a system of linear equations A*X = B with
   a real symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by SSYTRF_ROOK.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by SSYTRF_ROOK.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by SSYTRF_ROOK.

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine stgsyl (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
           STGSYL

Function/Subroutine Documentation
   subroutine stgsyl (character TRANS, integer IJOB, integer M, integer N,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( ldc, * ) C, integer LDC, real, dimension(
       ldd, * ) D, integer LDD, real, dimension( lde, * ) E, integer LDE,
       real, dimension( ldf, * ) F, integer LDF, real SCALE, real DIF, real,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer INFO)
       STGSYL

Purpose:
   STGSYL solves the generalized Sylvester equation:

                   A * R - L * B = scale * C                 (1)
                   D * R - L * E = scale * F

   where R and L are unknown m-by-n matrices, (A, D), (B, E) and
   (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n,
   respectively, with real entries. (A, D) and (B, E) must be in
   generalized (real) Schur canonical form, i.e. A, B are upper quasi
```

```
  triangular and D, E are upper triangular.

  The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output
  scaling factor chosen to avoid overflow.

  In matrix notation (1) is equivalent to solve  Zx = scale b, where
  Z is defined as

                 Z = [ kron(In, A)  -kron(B**T, Im) ]         (2)
                     [ kron(In, D)  -kron(E**T, Im) ].

  Here Ik is the identity matrix of size k and X**T is the transpose of
  X. kron(X, Y) is the Kronecker product between the matrices X and Y.

  If TRANS = 'T', STGSYL solves the transposed system Z**T*y = scale*b,
  which is equivalent to solve for R and L in

                  A**T * R + D**T * L = scale * C           (3)
                  R * B**T + L * E**T = scale * -F

  This case (TRANS = 'T') is used to compute an one-norm-based estimate
  of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D)
  and (B,E), using SLACON.

  If IJOB >= 1, STGSYL computes a Frobenius norm-based estimate
  of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the
  reciprocal of the smallest singular value of Z. See [1-2] for more
  information.

  This is a level 3 BLAS algorithm.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N', solve the generalized Sylvester equation (1).
   = 'T', solve the 'transposed' system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   =0: solve (1) only.
   =1: The functionality of 0 and 3.
   =2: The functionality of 0 and 4.
   =3: Only an estimate of Dif[(A,D), (B,E)] is computed.
       (look ahead strategy IJOB  = 1 is used).
   =4: Only an estimate of Dif[(A,D), (B,E)] is computed.
       ( SGECON on sub-systems is used ).
   Not referenced if TRANS = 'T'.
```

```
M
  M is INTEGER
  The order of the matrices A and D, and the row dimension of
  the matrices C, F, R and L.

N
  N is INTEGER
  The order of the matrices B and E, and the column dimension
  of the matrices C, F, R and L.

A
  A is REAL array, dimension (LDA, M)
  The upper quasi triangular matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1, M).

B
  B is REAL array, dimension (LDB, N)
  The upper quasi triangular matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1, N).

C
  C is REAL array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, C has been overwritten by
  the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R,
  the solution achieved during the computation of the Dif-estimate.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1, M).

D
  D is REAL array, dimension (LDD, M)
  The upper triangular matrix D.

LDD
  LDD is INTEGER
  The leading dimension of the array D. LDD >= max(1, M).

E
  E is REAL array, dimension (LDE, N)
  The upper triangular matrix E.
```

```
LDE
  LDE is INTEGER
  The leading dimension of the array E. LDE >= max(1, N).

F
  F is REAL array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, F has been overwritten by
  the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L,
  the solution achieved during the computation of the Dif-estimate.

LDF
  LDF is INTEGER
  The leading dimension of the array F. LDF >= max(1, M).

DIF
  DIF is REAL
  On exit DIF is the reciprocal of a lower bound of the
  reciprocal of the Dif-function, i.e. DIF is an upper bound of
  Dif[(A,D), (B,E)] = sigma_min(Z), where Z as in (2).
  IF IJOB = 0 or TRANS = 'T', DIF is not touched.

SCALE
  SCALE is REAL
  On exit SCALE is the scaling factor in (1) or (3).
  If 0 < SCALE < 1, C and F hold the solutions R and L, resp.,
  to a slightly perturbed system but the input matrices A, B, D
  and E have not been changed. If SCALE = 0, C and F hold the
  solutions R and L, respectively, to the homogeneous system
  with C = F = 0. Normally, SCALE = 1.

WORK
  WORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK > = 1.
  If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (M+N+6)

INFO
```

```
INFO is INTEGER
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or close eigenvalues.
```

SYNOPSIS
   Functions/Subroutines
       subroutine strsyl (TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
           SCALE, INFO)
           STRSYL

Function/Subroutine Documentation
   subroutine strsyl (character TRANA, character TRANB, integer ISGN, integer
       M, integer N, real, dimension( lda, * ) A, integer LDA, real,
```

```
      dimension( ldb, * ) B, integer LDB, real, dimension( ldc, * ) C,
      integer LDC, real SCALE, integer INFO)
      STRSYL

Purpose:
   STRSYL solves the real Sylvester matrix equation:

               op(A)*X + X*op(B) = scale*C or
               op(A)*X - X*op(B) = scale*C,

   where op(A) = A or A**T, and  A and B are both upper quasi-
   triangular. A is M-by-M and B is N-by-N; the right hand side C and
   the solution X are M-by-N; and scale is an output scale factor, set
   <= 1 to avoid overflow in X.

   A and B must be in Schur canonical form (as returned by SHSEQR), that
   is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks;
   each 2-by-2 diagonal block has its diagonal elements equal and its
   off-diagonal elements of opposite sign.

Parameters:

 TRANA
   TRANA is CHARACTER*1
   Specifies the option op(A):
   = 'N': op(A) = A    (No transpose)
   = 'T': op(A) = A**T (Transpose)
   = 'C': op(A) = A**H (Conjugate transpose = Transpose)

 TRANB
   TRANB is CHARACTER*1
   Specifies the option op(B):
   = 'N': op(B) = B    (No transpose)
   = 'T': op(B) = B**T (Transpose)
   = 'C': op(B) = B**H (Conjugate transpose = Transpose)

 ISGN
   ISGN is INTEGER
   Specifies the sign in the equation:
   = +1: solve op(A)*X + X*op(B) = scale*C
   = -1: solve op(A)*X - X*op(B) = scale*C

 M
   M is INTEGER
   The order of the matrix A, and the number of rows in the
   matrices X and C. M >= 0.

 N
   N is INTEGER
   The order of the matrix B, and the number of columns in the
```

```
  matrices X and C. N >= 0.

A
  A is REAL array, dimension (LDA,M)
  The upper quasi-triangular matrix A, in Schur canonical form.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

B
  B is REAL array, dimension (LDB,N)
  The upper quasi-triangular matrix B, in Schur canonical form.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

C
  C is REAL array, dimension (LDC,N)
  On entry, the M-by-N right hand side matrix C.
  On exit, C is overwritten by the solution matrix X.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M)

SCALE
  SCALE is REAL
  The scale factor, scale, set <= 1 to avoid overflow in X.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1: A and B have common or very close eigenvalues; perturbed
       values were used to solve the equation (but the matrices
       A and B are unchanged).
```
