SYNOPSIS
   Functions/Subroutines
       subroutine cla_syamv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           CLA_SYAMV computes a matrix-vector product using a symmetric
           indefinite matrix to calculate error bounds.

Function/Subroutine Documentation
   subroutine cla_syamv (integer UPLO, integer N, real ALPHA, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( * ) X, integer
       INCX, real BETA, real, dimension( * ) Y, integer INCY)
       CLA_SYAMV computes a matrix-vector product using a symmetric indefinite
       matrix to calculate error bounds.

Purpose:
   CLA_SYAMV  performs the matrix-vector operation

                    y := alpha*abs(A)*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   n by n symmetric matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 UPLO
   UPLO is INTEGER
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as
   follows:

   UPLO = BLAS_UPPER   Only the upper triangular part of A is to be referenced.
   UPLO = BLAS_LOWER   Only the lower triangular part of A is to be referenced.

   Unchanged on exit.

 N
   N is INTEGER
```

```
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is REAL .
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is COMPLEX array of DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
  Unchanged on exit.

X
  X is COMPLEX array, dimension
  ( 1 + ( n - 1 )*abs( INCX ) )
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is REAL .
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is REAL array, dimension
  ( 1 + ( n - 1 )*abs( INCY ) )
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
```

```
Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       real function cla_syrcond_c (UPLO, N, A, LDA, AF, LDAF, IPIV, C,
           CAPPLY, INFO, WORK, RWORK)
           CLA_SYRCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for symmetric indefinite matrices.

Function/Subroutine Documentation
   real function cla_syrcond_c (character UPLO, integer N, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF, integer
       LDAF, integer, dimension( * ) IPIV, real, dimension( * ) C, logical
       CAPPLY, integer INFO, complex, dimension( * ) WORK, real, dimension( *
       ) RWORK)
       CLA_SYRCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for symmetric indefinite matrices.

Purpose:
   CLA_SYRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a REAL vector.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by CSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF.

C
  C is REAL array, dimension (N)
  The vector C in the formula op(A) * inv(diag(C)).

CAPPLY
  CAPPLY is LOGICAL
  If .TRUE. then access the vector C in the formula above.

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX array, dimension (2*N).
  Workspace.

RWORK
  RWORK is REAL array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
       real function cla_syrcond_x (UPLO, N, A, LDA, AF, LDAF, IPIV, X, INFO,
           WORK, RWORK)
           CLA_SYRCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for symmetric indefinite matrices.

Function/Subroutine Documentation
   real function cla_syrcond_x (character UPLO, integer N, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF, integer
       LDAF, integer, dimension( * ) IPIV, complex, dimension( * ) X, integer
       INFO, complex, dimension( * ) WORK, real, dimension( * ) RWORK)
       CLA_SYRCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for symmetric indefinite matrices.

Purpose:
   CLA_SYRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by CSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
```

```
  as determined by CSYTRF.

X
  X is COMPLEX array, dimension (N)
  The vector X in the formula op(A) * diag(X).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX array, dimension (2*N).
  Workspace.

RWORK
  RWORK is REAL array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cla_syrfsx_extended (PREC_TYPE, UPLO, N, NRHS, A, LDA, AF,
           LDAF, IPIV, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS,
           ERR_BNDS_NORM, ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH,
           RTHRESH, DZ_UB, IGNORE_CWISE, INFO)
           CLA_SYRFSX_EXTENDED improves the computed solution to a system of
           linear equations for symmetric indefinite matrices by performing
           extra-precise iterative refinement and provides error bounds and
           backward error estimates for the solution.

       CLA_SYRFSX_EXTENDED improves the computed solution to a system of
       linear equations for symmetric indefinite matrices by performing extra-
       precise iterative refinement and provides error bounds and backward
       error estimates for the solution.

Purpose:
   CLA_SYRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by CSYRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra
```

```
UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by CSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF.

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
```

```
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by CSYTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
     max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
          max_j (abs(XTRUE(j,i) - X(j,i)))
           ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
```

```
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:
```

```
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is REAL array, dimension (N)
  Workspace.

DY
  DY is COMPLEX array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
```

```
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to CLA_SYRFSX_EXTENDED had an illegal
  value

SYNOPSIS
   Functions/Subroutines
       real function cla_syrpvgrw (UPLO, N, INFO, A, LDA, AF, LDAF, IPIV,
           WORK)
           CLA_SYRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric indefinite matrix.

Function/Subroutine Documentation
```

```
   real function cla_syrpvgrw (character*1 UPLO, integer N, integer INFO,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( ldaf,
       * ) AF, integer LDAF, integer, dimension( * ) IPIV, real, dimension( *
       ) WORK)
       CLA_SYRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a symmetric indefinite matrix.

Purpose:
   CLA_SYRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 INFO
   INFO is INTEGER
   The value of INFO returned from CSYTRF, .i.e., the pivot in
   column INFO is exactly 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by CSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
```

```
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by CSYTRF.

 WORK
   WORK is REAL array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine clasyf (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           CLASYF computes a partial factorization of a complex symmetric
           matrix using the Bunch-Kaufman diagonal pivoting method.
```

```
Function/Subroutine Documentation
   subroutine clasyf (character UPLO, integer N, integer NB, integer KB,
       complex, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, complex, dimension( ldw, * ) W, integer LDW, integer INFO)
       CLASYF computes a partial factorization of a complex symmetric matrix
       using the Bunch-Kaufman diagonal pivoting method.

Purpose:
   CLASYF computes a partial factorization of a complex symmetric matrix
   A using the Bunch-Kaufman diagonal pivoting method. The partial
   factorization has the form:

       A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
             ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

       A  =  ( L11  0 ) ( D    0  ) ( L11**T L21**T )  if UPLO = 'L'
             ( L21  I ) ( 0   A22 ) (  0       I    )

   where the order of D is at most NB. The actual order is returned in
   the argument KB, and is either NB or NB-1, or N if N <= NB.
   Note that U**T denotes the transpose of U.

   CLASYF is an auxiliary routine called by CSYTRF. It uses blocked code
   (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or
   A22 (if UPLO = 'L').

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NB
   NB is INTEGER
   The maximum number of columns of the matrix A that should be
   factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

 KB
   KB is INTEGER
   The number of columns of A that were actually factored.
   KB is either NB-1 or NB, or N if N <= NB.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     Only the last KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k-1) < 0, then rows and columns
     k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
     is a 2-by-2 diagonal block.

  If UPLO = 'L':
     Only the first KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k+1) < 0, then rows and columns
     k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
     is a 2-by-2 diagonal block.

W
  W is COMPLEX array, dimension (LDW,NB)

LDW
  LDW is INTEGER
  The leading dimension of the array W.  LDW >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
```

```
       has been completed, but the block diagonal matrix D is
       exactly singular.
```

SYNOPSIS
   Functions/Subroutines
       subroutine clasyf_rook (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           CLASYF_ROOK computes a partial factorization of a complex symmetric
           matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
```

```
          method.

Function/Subroutine Documentation
   subroutine clasyf_rook (character UPLO, integer N, integer NB, integer KB,
       complex, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, complex, dimension( ldw, * ) W, integer LDW, integer INFO)
       CLASYF_ROOK computes a partial factorization of a complex symmetric
       matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
       method.

Purpose:
   CLASYF_ROOK computes a partial factorization of a complex symmetric
   matrix A using the bounded Bunch-Kaufman ("rook") diagonal
   pivoting method. The partial factorization has the form:

       A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
             ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

       A  =  ( L11  0 ) (  D   0  ) ( L11**T L21**T )  if UPLO = 'L'
             ( L21  I ) (  0  A22 ) (  0       I    )

   where the order of D is at most NB. The actual order is returned in
   the argument KB, and is either NB or NB-1, or N if N <= NB.

   CLASYF_ROOK is an auxiliary routine called by CSYTRF_ROOK. It uses
   blocked code (calling Level 3 BLAS) to update the submatrix
   A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NB
   NB is INTEGER
   The maximum number of columns of the matrix A that should be
   factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

 KB
   KB is INTEGER
   The number of columns of A that were actually factored.
   KB is either NB-1 or NB, or N if N <= NB.
```

```
A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     Only the last KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
     Only the first KB elements of IPIV are set.

     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W
  W is COMPLEX array, dimension (LDW,NB)

LDW
  LDW is INTEGER
  The leading dimension of the array W.  LDW >= max(1,N).

INFO
```

```
INFO is INTEGER
= 0: successful exit
> 0: if INFO = k, D(k,k) is exactly zero.  The factorization
     has been completed, but the block diagonal matrix D is
     exactly singular.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csycon (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
           CSYCON

Function/Subroutine Documentation
   subroutine csycon (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, real ANORM, real RCOND,
       complex, dimension( * ) WORK, integer INFO)
       CSYCON

Purpose:
   CSYCON estimates the reciprocal of the condition number (in the
   1-norm) of a complex symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by CSYTRF.
```

```
   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by CSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by CSYTRF.

 ANORM
   ANORM is REAL
   The 1-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
   estimate of the 1-norm of inv(A) computed in this routine.

 WORK
   WORK is COMPLEX array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

SYNOPSIS
   Functions/Subroutines
       subroutine csycon_rook (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK,
           INFO)
           CSYCON_ROOK

Function/Subroutine Documentation
   subroutine csycon_rook (character UPLO, integer N, complex, dimension( lda,
```

```
      * ) A, integer LDA, integer, dimension( * ) IPIV, real ANORM, real
      RCOND, complex, dimension( * ) WORK, integer INFO)
      CSYCON_ROOK

Purpose:
   CSYCON_ROOK estimates the reciprocal of the condition number (in the
   1-norm) of a complex symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by CSYTRF_ROOK.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by CSYTRF_ROOK.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by CSYTRF_ROOK.

 ANORM
   ANORM is REAL
   The 1-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
   estimate of the 1-norm of inv(A) computed in this routine.

 WORK
```

```
  WORK is COMPLEX array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine csyconv (UPLO, WAY, N, A, LDA, IPIV, E, INFO)
           CSYCONV

Function/Subroutine Documentation
   subroutine csyconv (character UPLO, character WAY, integer N, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( * ) E, integer INFO)
       CSYCONV

Purpose:
   CSYCONV convert A given by TRF into L and D and vice-versa.
   Get Non-diag elements of D (returned in workspace) and
   apply or reverse permutation done in TRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 WAY
   WAY is CHARACTER*1
   = 'C': Convert
   = 'R': Revert

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by CSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
```

```
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF.

E
  E is COMPLEX array, dimension (N)
  E stores the supdiagonal/subdiagonal of the symmetric 1-by-1
  or 2-by-2 block diagonal matrix D in LDLT.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine csyequb (UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
           CSYEQUB
```

```
Function/Subroutine Documentation
   subroutine csyequb (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, real, dimension( * ) S, real SCOND, real AMAX, complex,
       dimension( * ) WORK, integer INFO)
       CSYEQUB

Purpose:
   CSYEQUB computes row and column scalings intended to equilibrate a
   symmetric matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The N-by-N symmetric matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is REAL array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is REAL
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
```

```
   AMAX is REAL
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix should be scaled.

 WORK
   WORK is COMPLEX array, dimension (3*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csyrfs (UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, RWORK, INFO)
           CSYRFS

Function/Subroutine Documentation
   subroutine csyrfs (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF,
       integer LDAF, integer, dimension( * ) IPIV, complex, dimension( ldb, *
       ) B, integer LDB, complex, dimension( ldx, * ) X, integer LDX, real,
       dimension( * ) FERR, real, dimension( * ) BERR, complex, dimension( * )
       WORK, real, dimension( * ) RWORK, integer INFO)
       CSYRFS

Purpose:
   CSYRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
```

```
  A is COMPLEX array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The factored form of the matrix A.  AF contains the block
  diagonal matrix D and the multipliers used to obtain the
  factor U or L from the factorization A = U*D*U**T or
  A = L*D*L**T as computed by CSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CSYTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
```

```
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is REAL array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX array, dimension (2*N)

 RWORK
   RWORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csyrfsx (UPLO, EQUED, N, NRHS, A, LDA, AF, LDAF, IPIV, S, B,
           LDB, X, LDX, RCOND, BERR, N_ERR_BNDS, ERR_BNDS_NORM, ERR_BNDS_COMP,
           NPARAMS, PARAMS, WORK, RWORK, INFO)
           CSYRFSX

Function/Subroutine Documentation
   subroutine csyrfsx (character UPLO, character EQUED, integer N, integer
       NRHS, complex, dimension( lda, * ) A, integer LDA, complex, dimension(
       ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, real,
       dimension( * ) S, complex, dimension( ldb, * ) B, integer LDB, complex,
       dimension( ldx, * ) X, integer LDX, real RCOND, real, dimension( * )
       BERR, integer N_ERR_BNDS, real, dimension( nrhs, * ) ERR_BNDS_NORM,
       real, dimension( nrhs, * ) ERR_BNDS_COMP, integer NPARAMS, real,
       dimension( * ) PARAMS, complex, dimension( * ) WORK, real, dimension( *
       ) RWORK, integer INFO)
       CSYRFSX

Purpose:
   CSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular
   part of the matrix A, and the strictly lower triangular
   part of A is not referenced.  If UPLO = 'L', the leading
   N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The factored form of the matrix A.  AF contains the block
   diagonal matrix D and the multipliers used to obtain the
   factor U or L from the factorization A = U*D*U**T or A =
   L*D*L**T as computed by SSYTRF.

 LDAF
   LDAF is INTEGER
```

```
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by SSYTRF.

S
  S is REAL array, dimension (N)
  The scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
```

```
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
          max_j (abs(XTRUE(j,i) - X(j,i)))
           ------------------------------
                 max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.
```

```
ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.
```

```
PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
```

```
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csytf2 (UPLO, N, A, LDA, IPIV, INFO)
           CSYTF2 computes the factorization of a real symmetric indefinite
           matrix, using the diagonal pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine csytf2 (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       CSYTF2 computes the factorization of a real symmetric indefinite
       matrix, using the diagonal pivoting method (unblocked algorithm).

Purpose:
   CSYTF2 computes the factorization of a complex symmetric matrix A
   using the Bunch-Kaufman diagonal pivoting method:

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is stored:
  = 'U':  Upper triangular
  = 'L':  Lower triangular

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k-1) < 0, then rows and columns
     k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
     is a 2-by-2 diagonal block.

  If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k+1) < 0, then rows and columns
     k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
     is a 2-by-2 diagonal block.

INFO
```

```
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:
   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
             U(k) =    (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine csytf2_rook (UPLO, N, A, LDA, IPIV, INFO)
           CSYTF2_ROOK computes the factorization of a complex symmetric
           indefinite matrix using the bounded Bunch-Kaufman ('rook') diagonal
           pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine csytf2_rook (character UPLO, integer N, complex, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       CSYTF2_ROOK computes the factorization of a complex symmetric
       indefinite matrix using the bounded Bunch-Kaufman ('rook') diagonal
       pivoting method (unblocked algorithm).

Purpose:
   CSYTF2_ROOK computes the factorization of a complex symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
```

```
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

   If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then
```

```
                    (   I    v    0   )   k-s
             U(k) =  (   0    I    0   )   s
                    (   0    0    I   )   n-k
                       k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                    (   I    0     0   )  k-1
             L(k) =  (   0    I     0   )  s
                    (   0    v     I   )  n-k-s+1
                       k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine csytrf (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           CSYTRF

Function/Subroutine Documentation
   subroutine csytrf (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, complex, dimension( * )
       WORK, integer LWORK, integer INFO)
       CSYTRF

Purpose:
   CSYTRF computes the factorization of a complex symmetric matrix A
   using the Bunch-Kaufman diagonal pivoting method.  The form of the
   factorization is

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   with 1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
```

```
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
     has been completed, but the block diagonal matrix D is
     exactly singular, and division by zero will occur if it
     is used to solve a system of equations.

Further Details:

  If UPLO = 'U', then A = U*D*U**T, where
     U = P(n)*U(n)* ... *P(k)U(k)* ...,
  i.e., U is a product of terms P(k)*U(k), where k decreases from n to
  1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
```

```
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
             U(k) =    (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine csytrf_rook (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           CSYTRF_ROOK

Function/Subroutine Documentation
   subroutine csytrf_rook (character UPLO, integer N, complex, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, complex, dimension( *
       ) WORK, integer LWORK, integer INFO)
       CSYTRF_ROOK

Purpose:
   CSYTRF_ROOK computes the factorization of a complex symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.
   The form of the factorization is

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
```

```
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k-1 and -IPIV(k-1) were inerchaged,
    D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k+1 and -IPIV(k+1) were inerchaged,
    D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK)).
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                        (   I    v    0   )   k-s
                U(k) =  (   0    I    0   )   s
                        (   0    0    I   )   n-k
                           k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                        (   I    0     0   )  k-1
                L(k) =  (   0    I     0   )  s
                        (   0    v     I   )  n-k-s+1
                           k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine csytri (UPLO, N, A, LDA, IPIV, WORK, INFO)
           CSYTRI

Function/Subroutine Documentation
   subroutine csytri (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, complex, dimension( * )
       WORK, integer INFO)
       CSYTRI

Purpose:
```

```
  CSYTRI computes the inverse of a complex symmetric indefinite matrix
  A using the factorization A = U*D*U**T or A = L*D*L**T computed by
  CSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by CSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by CSYTRF.

 WORK
   WORK is COMPLEX array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

==================================================================
Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine csytri2 (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           CSYTRI2

Function/Subroutine Documentation
   subroutine csytri2 (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer, dimension( * ) IPIV, complex, dimension( * )
       WORK, integer LWORK, integer INFO)
       CSYTRI2

Purpose:
   CSYTRI2 computes the inverse of a COMPLEX symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by
   CSYTRF. CSYTRI2 sets the LEADING DIMENSION of the workspace
   before calling CSYTRI2X that actually computes the inverse.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
```

```
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the NB diagonal matrix D and the multipliers
  used to obtain the factor U or L as computed by CSYTRF.

  On exit, if INFO = 0, the (symmetric) inverse of the original
  matrix.  If UPLO = 'U', the upper triangular part of the
  inverse is formed and the part of A below the diagonal is not
  referenced; if UPLO = 'L' the lower triangular part of the
  inverse is formed and the part of A above the diagonal is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the NB structure of D
  as determined by CSYTRF.

WORK
  WORK is COMPLEX array, dimension (N+NB+1)*(NB+3)

LWORK
  LWORK is INTEGER
  The dimension of the array WORK.
  WORK is size >= (N+NB+1)*(NB+3)
  If LDWORK = -1, then a workspace query is assumed; the routine
  calculates:
  - the optimal size of the WORK array, returns
  this value as the first entry of the WORK array,
  - and no error message related to LDWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
       inverse could not be computed.

SYNOPSIS
   Functions/Subroutines
       subroutine csytri2x (UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
           CSYTRI2X

Function/Subroutine Documentation
   subroutine csytri2x (character UPLO, integer N, complex, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, complex, dimension(
       n+nb+1,* ) WORK, integer NB, integer INFO)
       CSYTRI2X

Purpose:
   CSYTRI2X computes the inverse of a real symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF.

Parameters:
```

```
UPLO
  UPLO is CHARACTER*1
  Specifies whether the details of the factorization are stored
  as an upper or lower triangular matrix.
  = 'U':  Upper triangular, form is A = U*D*U**T;
  = 'L':  Lower triangular, form is A = L*D*L**T.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the NNB diagonal matrix D and the multipliers
  used to obtain the factor U or L as computed by CSYTRF.

  On exit, if INFO = 0, the (symmetric) inverse of the original
  matrix.  If UPLO = 'U', the upper triangular part of the
  inverse is formed and the part of A below the diagonal is not
  referenced; if UPLO = 'L' the lower triangular part of the
  inverse is formed and the part of A above the diagonal is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the NNB structure of D
  as determined by CSYTRF.

WORK
  WORK is COMPLEX array, dimension (N+NNB+1,NNB+3)

NB
  NB is INTEGER
  Block size

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
       inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csytri_rook (UPLO, N, A, LDA, IPIV, WORK, INFO)
           CSYTRI_ROOK

Function/Subroutine Documentation
   subroutine csytri_rook (character UPLO, integer N, complex, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, complex, dimension( *
       ) WORK, integer INFO)
       CSYTRI_ROOK

Purpose:
            CSYTRI_ROOK computes the inverse of a complex symmetric
            matrix A using the factorization A = U*D*U**T or A = L*D*L**T
            computed by CSYTRF_ROOK.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by CSYTRF_ROOK.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by CSYTRF_ROOK.

 WORK
   WORK is COMPLEX array, dimension (N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csytrs (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           CSYTRS

Function/Subroutine Documentation
   subroutine csytrs (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, integer INFO)
       CSYTRS

Purpose:
   CSYTRS solves a system of linear equations A*X = B with a complex
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by CSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
```

```
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by CSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine csytrs2 (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
           CSYTRS2

Function/Subroutine Documentation
   subroutine csytrs2 (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, complex, dimension( * )
       WORK, integer INFO)
       CSYTRS2

Purpose:
   CSYTRS2 solves a system of linear equations A*X = B with a COMPLEX
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by CSYTRF and converted by CSYCONV.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
```

```
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by CSYTRF.
  Note that A is input / output. This might be counter-intuitive,
  and one may think that A is input only. A is input / output. This
  is because, at the start of the subroutine, we permute A in a
  "better" form and then we permute A back to its original form at the end.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

WORK
  WORK is COMPLEX array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine csytrs_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           CSYTRS_ROOK

Function/Subroutine Documentation
   subroutine csytrs_rook (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex, dimension( ldb, * ) B, integer LDB, integer INFO)
       CSYTRS_ROOK

Purpose:
   CSYTRS_ROOK solves a system of linear equations A*X = B with
   a complex symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by CSYTRF_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
```

```
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by CSYTRF_ROOK.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by CSYTRF_ROOK.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctgsyl (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
           CTGSYL

Function/Subroutine Documentation
   subroutine ctgsyl (character TRANS, integer IJOB, integer M, integer N,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( ldb, *
       ) B, integer LDB, complex, dimension( ldc, * ) C, integer LDC, complex,
       dimension( ldd, * ) D, integer LDD, complex, dimension( lde, * ) E,
       integer LDE, complex, dimension( ldf, * ) F, integer LDF, real SCALE,
       real DIF, complex, dimension( * ) WORK, integer LWORK, integer,
       dimension( * ) IWORK, integer INFO)
       CTGSYL

Purpose:
   CTGSYL solves the generalized Sylvester equation:

                   A * R - L * B = scale * C            (1)
                   D * R - L * E = scale * F

   where R and L are unknown m-by-n matrices, (A, D), (B, E) and
   (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n,
```

```
  respectively, with complex entries. A, B, D and E are upper
  triangular (i.e., (A,D) and (B,E) in generalized Schur form).

  The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1
  is an output scaling factor chosen to avoid overflow.

  In matrix notation (1) is equivalent to solve Zx = scale*b, where Z
  is defined as

             Z = [ kron(In, A)  -kron(B**H, Im) ]        (2)
                 [ kron(In, D)  -kron(E**H, Im) ],

  Here Ix is the identity matrix of size x and X**H is the conjugate
  transpose of X. Kron(X, Y) is the Kronecker product between the
  matrices X and Y.

  If TRANS = 'C', y in the conjugate transposed system Z**H *y = scale*b
  is solved for, which is equivalent to solve for R and L in

                  A**H * R + D**H * L = scale * C           (3)
                  R * B**H + L * E**H = scale * -F

  This case (TRANS = 'C') is used to compute an one-norm-based estimate
  of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D)
  and (B,E), using CLACON.

  If IJOB >= 1, CTGSYL computes a Frobenius norm-based estimate of
  Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the
  reciprocal of the smallest singular value of Z.

  This is a level-3 BLAS algorithm.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N': solve the generalized sylvester equation (1).
   = 'C': solve the "conjugate transposed" system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   =0: solve (1) only.
   =1: The functionality of 0 and 3.
   =2: The functionality of 0 and 4.
   =3: Only an estimate of Dif[(A,D), (B,E)] is computed.
       (look ahead strategy is used).
   =4: Only an estimate of Dif[(A,D), (B,E)] is computed.
       (CGECON on sub-systems is used).
   Not referenced if TRANS = 'C'.
```

```
M
  M is INTEGER
  The order of the matrices A and D, and the row dimension of
  the matrices C, F, R and L.

N
  N is INTEGER
  The order of the matrices B and E, and the column dimension
  of the matrices C, F, R and L.

A
  A is COMPLEX array, dimension (LDA, M)
  The upper triangular matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1, M).

B
  B is COMPLEX array, dimension (LDB, N)
  The upper triangular matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1, N).

C
  C is COMPLEX array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, C has been overwritten by
  the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R,
  the solution achieved during the computation of the Dif-estimate.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1, M).

D
  D is COMPLEX array, dimension (LDD, M)
  The upper triangular matrix D.

LDD
  LDD is INTEGER
  The leading dimension of the array D. LDD >= max(1, M).

E
  E is COMPLEX array, dimension (LDE, N)
  The upper triangular matrix E.
```

```
LDE
  LDE is INTEGER
  The leading dimension of the array E. LDE >= max(1, N).

F
  F is COMPLEX array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, F has been overwritten by
  the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L,
  the solution achieved during the computation of the Dif-estimate.

LDF
  LDF is INTEGER
  The leading dimension of the array F. LDF >= max(1, M).

DIF
  DIF is REAL
  On exit DIF is the reciprocal of a lower bound of the
  reciprocal of the Dif-function, i.e. DIF is an upper bound of
  Dif[(A,D), (B,E)] = sigma-min(Z), where Z as in (2).
  IF IJOB = 0 or TRANS = 'C', DIF is not referenced.

SCALE
  SCALE is REAL
  On exit SCALE is the scaling factor in (1) or (3).
  If 0 < SCALE < 1, C and F hold the solutions R and L, resp.,
  to a slightly perturbed system but the input matrices A, B,
  D and E have not been changed. If SCALE = 0, R and L will
  hold the solutions to the homogenious system with C = F = 0.

WORK
  WORK is COMPLEX array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The dimension of the array WORK. LWORK > = 1.
  If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

IWORK
  IWORK is INTEGER array, dimension (M+N+2)

INFO
```

```
INFO is INTEGER
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or very close
    eigenvalues.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ctrsyl (TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
           SCALE, INFO)
```

```
          CTRSYL

Function/Subroutine Documentation
   subroutine ctrsyl (character TRANA, character TRANB, integer ISGN, integer
       M, integer N, complex, dimension( lda, * ) A, integer LDA, complex,
       dimension( ldb, * ) B, integer LDB, complex, dimension( ldc, * ) C,
       integer LDC, real SCALE, integer INFO)
       CTRSYL

Purpose:
   CTRSYL solves the complex Sylvester matrix equation:

   op(A)*X + X*op(B) = scale*C or
   op(A)*X - X*op(B) = scale*C,

   where op(A) = A or A**H, and A and B are both upper triangular. A is
   M-by-M and B is N-by-N; the right hand side C and the solution X are
   M-by-N; and scale is an output scale factor, set <= 1 to avoid
   overflow in X.

Parameters:

 TRANA
   TRANA is CHARACTER*1
   Specifies the option op(A):
   = 'N': op(A) = A    (No transpose)
   = 'C': op(A) = A**H (Conjugate transpose)

 TRANB
   TRANB is CHARACTER*1
   Specifies the option op(B):
   = 'N': op(B) = B    (No transpose)
   = 'C': op(B) = B**H (Conjugate transpose)

 ISGN
   ISGN is INTEGER
   Specifies the sign in the equation:
   = +1: solve op(A)*X + X*op(B) = scale*C
   = -1: solve op(A)*X - X*op(B) = scale*C

 M
   M is INTEGER
   The order of the matrix A, and the number of rows in the
   matrices X and C. M >= 0.

 N
   N is INTEGER
   The order of the matrix B, and the number of columns in the
   matrices X and C. N >= 0.
```

```
A
  A is COMPLEX array, dimension (LDA,M)
  The upper triangular matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

B
  B is COMPLEX array, dimension (LDB,N)
  The upper triangular matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

C
  C is COMPLEX array, dimension (LDC,N)
  On entry, the M-by-N right hand side matrix C.
  On exit, C is overwritten by the solution matrix X.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M)

SCALE
  SCALE is REAL
  The scale factor, scale, set <= 1 to avoid overflow in X.

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1: A and B have common or very close eigenvalues; perturbed
       values were used to solve the equation (but the matrices
       A and B are unchanged).
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zla_syamv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           ZLA_SYAMV computes a matrix-vector product using a symmetric
           indefinite matrix to calculate error bounds.

Function/Subroutine Documentation
   subroutine zla_syamv (integer UPLO, integer N, double precision ALPHA,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       * ) X, integer INCX, double precision BETA, double precision,
       dimension( * ) Y, integer INCY)
       ZLA_SYAMV computes a matrix-vector product using a symmetric indefinite
       matrix to calculate error bounds.

Purpose:
   ZLA_SYAMV  performs the matrix-vector operation

   y := alpha*abs(A)*abs(x) + beta*abs(y),

   where alpha and beta are scalars, x and y are vectors and A is an
   n by n symmetric matrix.

   This function is primarily used in calculating error bounds.
   To protect against underflow during evaluation, components in
   the resulting vector are perturbed away from zero by (N+1)
   times the underflow threshold.  To prevent unnecessarily large
   errors for block-structure embedded in general matrices,
   "symbolically" zero components are not perturbed.  A zero
   entry is considered "symbolic" if all multiplications involved
   in computing that entry have at least one zero multiplicand.

Parameters:

 UPLO
   UPLO is INTEGER
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as follows:

   UPLO = BLAS_UPPER   Only the upper triangular part of A is to be referenced.
   UPLO = BLAS_LOWER   Only the lower triangular part of A is to be referenced.

   Unchanged on exit.

 N
   N is INTEGER
```

```
  On entry, N specifies the number of columns of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is DOUBLE PRECISION .
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is COMPLEX*16 array, DIMENSION ( LDA, n ).
  Before entry, the leading m by n part of the array A must
  contain the matrix of coefficients.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, n ).
  Unchanged on exit.

X
  X is COMPLEX*16 array, DIMENSION at least
  ( 1 + ( n - 1 )*abs( INCX ) )
  Before entry, the incremented array X must contain the vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is DOUBLE PRECISION .
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is DOUBLE PRECISION array, dimension
  ( 1 + ( n - 1 )*abs( INCY ) )
  Before entry with BETA non-zero, the incremented array Y
  must contain the vector y. On exit, Y is overwritten by the
  updated vector y.

INCY
  INCY is INTEGER
  On entry, INCY specifies the increment for the elements of
  Y. INCY must not be zero.
```

```
Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_syrcond_c (UPLO, N, A, LDA, AF, LDAF,
           IPIV, C, CAPPLY, INFO, WORK, RWORK)
           ZLA_SYRCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for symmetric indefinite matrices.

Function/Subroutine Documentation
   double precision function zla_syrcond_c (character UPLO, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, double
       precision, dimension( * ) C, logical CAPPLY, integer INFO, complex*16,
       dimension( * ) WORK, double precision, dimension( * ) RWORK)
       ZLA_SYRCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for symmetric indefinite matrices.

Purpose:
   ZLA_SYRCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A
```

```
LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by ZSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by ZSYTRF.

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * inv(diag(C)).

CAPPLY
  CAPPLY is LOGICAL
  If .TRUE. then access the vector C in the formula above.

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX*16 array, dimension (2*N).
  Workspace.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
```

```
      double precision function zla_syrcond_x (UPLO, N, A, LDA, AF, LDAF,
          IPIV, X, INFO, WORK, RWORK)
          ZLA_SYRCOND_X computes the infinity norm condition number of
          op(A)*diag(x) for symmetric indefinite matrices.

Function/Subroutine Documentation
   double precision function zla_syrcond_x (character UPLO, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, integer, dimension( * ) IPIV, complex*16,
       dimension( * ) X, integer INFO, complex*16, dimension( * ) WORK, double
       precision, dimension( * ) RWORK)
       ZLA_SYRCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for symmetric indefinite matrices.

Purpose:
   ZLA_SYRCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX*16 vector.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF.
```

```
 X
   X is COMPLEX*16 array, dimension (N)
   The vector X in the formula op(A) * diag(X).

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
   WORK is COMPLEX*16 array, dimension (2*N).
   Workspace.

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N).
   Workspace.
```

       DZ_UB, logical IGNORE_CWISE, integer INFO)
       ZLA_SYRFSX_EXTENDED improves the computed solution to a system of
       linear equations for symmetric indefinite matrices by performing extra-
       precise iterative refinement and provides error bounds and backward
       error estimates for the solution.

Purpose:
   ZLA_SYRFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by ZSYRFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
```

```
  P    = 'S':  Single
       = 'D':  Double
       = 'I':  Indigenous
       = 'X', 'E':  Extra

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right-hand-sides, i.e., the number of columns of the
  matrix B.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by ZSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by ZSYTRF.

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
```

```
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX*16 array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by ZSYTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                   max_j abs(X(j,i))
```

```
  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.
```

```
  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace.

DY
  DY is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX*16 array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
```

```
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is DOUBLE PRECISION
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is DOUBLE PRECISION
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to ZLA_HERFSX_EXTENDED had an illegal
  value

SYNOPSIS
   Functions/Subroutines
       double precision function zla_syrpvgrw (UPLO, N, INFO, A, LDA, AF,
           LDAF, IPIV, WORK)
           ZLA_SYRPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric indefinite matrix.

Function/Subroutine Documentation
   double precision function zla_syrpvgrw (character*1 UPLO, integer N,
       integer INFO, complex*16, dimension( lda, * ) A, integer LDA,
       complex*16, dimension( ldaf, * ) AF, integer LDAF, integer, dimension(
       * ) IPIV, double precision, dimension( * ) WORK)
       ZLA_SYRPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a symmetric indefinite matrix.

Purpose:
   ZLA_SYRPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 INFO
   INFO is INTEGER
   The value of INFO returned from ZSYTRF, .i.e., the pivot in
   column INFO is exactly 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A.
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF.

 WORK
   WORK is DOUBLE PRECISION array, dimension (2*N)
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zlasyf (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           ZLASYF computes a partial factorization of a complex symmetric
           matrix using the Bunch-Kaufman diagonal pivoting method.

Function/Subroutine Documentation
   subroutine zlasyf (character UPLO, integer N, integer NB, integer KB,
       complex*16, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, complex*16, dimension( ldw, * ) W, integer LDW, integer INFO)
       ZLASYF computes a partial factorization of a complex symmetric matrix
       using the Bunch-Kaufman diagonal pivoting method.

Purpose:
   ZLASYF computes a partial factorization of a complex symmetric matrix
   A using the Bunch-Kaufman diagonal pivoting method. The partial
   factorization has the form:

       A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
             ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

       A  =  ( L11  0 ) ( D    0  ) ( L11**T L21**T )  if UPLO = 'L'
             ( L21  I ) ( 0   A22 ) (  0       I    )

   where the order of D is at most NB. The actual order is returned in
   the argument KB, and is either NB or NB-1, or N if N <= NB.
   Note that U**T denotes the transpose of U.

   ZLASYF is an auxiliary routine called by ZSYTRF. It uses blocked code
   (calling Level 3 BLAS) to update the submatrix A11 (if UPLO = 'U') or
   A22 (if UPLO = 'L').

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
```

```
  symmetric matrix A is stored:
  = 'U':  Upper triangular
  = 'L':  Lower triangular

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NB
  NB is INTEGER
  The maximum number of columns of the matrix A that should be
  factored.  NB should be at least 2 to allow for 2-by-2 pivot blocks.

KB
  KB is INTEGER
  The number of columns of A that were actually factored.
  KB is either NB-1 or NB, or N if N <= NB.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
    Only the last KB elements of IPIV are set.

    If IPIV(k) > 0, then rows and columns k and IPIV(k) were
    interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) = IPIV(k-1) < 0, then rows and columns
    k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
    is a 2-by-2 diagonal block.

  If UPLO = 'L':
    Only the first KB elements of IPIV are set.
```

```
     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k+1) < 0, then rows and columns
     k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
     is a 2-by-2 diagonal block.

 W
   W is COMPLEX*16 array, dimension (LDW,NB)

 LDW
   LDW is INTEGER
   The leading dimension of the array W.  LDW >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
        has been completed, but the block diagonal matrix D is
        exactly singular.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zlasyf_rook (UPLO, N, NB, KB, A, LDA, IPIV, W, LDW, INFO)
           ZLASYF_ROOK computes a partial factorization of a complex symmetric
           matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
           method.

Function/Subroutine Documentation
   subroutine zlasyf_rook (character UPLO, integer N, integer NB, integer KB,
       complex*16, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, complex*16, dimension( ldw, * ) W, integer LDW, integer INFO)
       ZLASYF_ROOK computes a partial factorization of a complex symmetric
       matrix using the bounded Bunch-Kaufman ('rook') diagonal pivoting
       method.

Purpose:
```

```
  ZLASYF_ROOK computes a partial factorization of a complex symmetric
  matrix A using the bounded Bunch-Kaufman ("rook") diagonal
  pivoting method. The partial factorization has the form:

      A  =  ( I  U12 ) ( A11  0  ) (  I       0    )  if UPLO = 'U', or:
            ( 0  U22 ) (  0   D  ) ( U12**T U22**T )

      A  =  ( L11  0 ) (  D   0  ) ( L11**T L21**T )  if UPLO = 'L'
            ( L21  I ) (  0  A22 ) (  0       I    )

  where the order of D is at most NB. The actual order is returned in
  the argument KB, and is either NB or NB-1, or N if N <= NB.

  ZLASYF_ROOK is an auxiliary routine called by ZSYTRF_ROOK. It uses
  blocked code (calling Level 3 BLAS) to update the submatrix
  A11 (if UPLO = 'U') or A22 (if UPLO = 'L').

Parameters:

 UPLO
  UPLO is CHARACTER*1
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is stored:
  = 'U':  Upper triangular
  = 'L':  Lower triangular

 N
  N is INTEGER
  The order of the matrix A.  N >= 0.

 NB
  NB is INTEGER
  The maximum number of columns of the matrix A that should be
  factored.  NB should be at least 2 to allow for 2-by-2 pivot
  blocks.

 KB
  KB is INTEGER
  The number of columns of A that were actually factored.
  KB is either NB-1 or NB, or N if N <= NB.

 A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n-by-n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n-by-n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.
```

```
  On exit, A contains details of the partial factorization.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
    Only the last KB elements of IPIV are set.

    If IPIV(k) > 0, then rows and columns k and IPIV(k) were
    interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k-1 and -IPIV(k-1) were inerchaged,
    D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
    Only the first KB elements of IPIV are set.

    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k+1 and -IPIV(k+1) were inerchaged,
    D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

W
  W is COMPLEX*16 array, dimension (LDW,NB)

LDW
  LDW is INTEGER
  The leading dimension of the array W.  LDW >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
       has been completed, but the block diagonal matrix D is
       exactly singular.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsycon (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK, INFO)
           ZSYCON

Function/Subroutine Documentation
   subroutine zsycon (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, double precision ANORM,
       double precision RCOND, complex*16, dimension( * ) WORK, integer INFO)
       ZSYCON

Purpose:
   ZSYCON estimates the reciprocal of the condition number (in the
   1-norm) of a complex symmetric matrix A using the factorization
   A = U*D*U**T or A = L*D*L**T computed by ZSYTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.
```

```
N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The block diagonal matrix D and the multipliers used to
  obtain the factor U or L as computed by ZSYTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by ZSYTRF.

ANORM
  ANORM is DOUBLE PRECISION
  The 1-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

SYNOPSIS
   Functions/Subroutines
       subroutine zsycon_rook (UPLO, N, A, LDA, IPIV, ANORM, RCOND, WORK,
           INFO)
           ZSYCON_ROOK

Function/Subroutine Documentation
   subroutine zsycon_rook (character UPLO, integer N, complex*16, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, double precision
       ANORM, double precision RCOND, complex*16, dimension( * ) WORK, integer
       INFO)
       ZSYCON_ROOK

Purpose:
   ZSYCON_ROOK estimates the reciprocal of the condition number (in the
   1-norm) of a complex symmetric matrix A using the factorization
```

```
   A = U*D*U**T or A = L*D*L**T computed by ZSYTRF_ROOK.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF_ROOK.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF_ROOK.

 ANORM
   ANORM is DOUBLE PRECISION
   The 1-norm of the original matrix A.

 RCOND
   RCOND is DOUBLE PRECISION
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
   estimate of the 1-norm of inv(A) computed in this routine.

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsyconv (UPLO, WAY, N, A, LDA, IPIV, E, INFO)
           ZSYCONV

Function/Subroutine Documentation
   subroutine zsyconv (character UPLO, character WAY, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex*16, dimension( * ) E, integer INFO)
       ZSYCONV

Purpose:
   ZSYCONV converts A given by ZHETRF into L and D or vice-versa.
   Get nondiagonal elements of D (returned in workspace) and
   apply or reverse permutation done in TRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 WAY
   WAY is CHARACTER*1
   = 'C': Convert
   = 'R': Revert

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF.

 E
   E is COMPLEX*16 array, dimension (N)
```

```
  E stores the supdiagonal/subdiagonal of the symmetric 1-by-1
  or 2-by-2 block diagonal matrix D in LDLT.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsyequb (UPLO, N, A, LDA, S, SCOND, AMAX, WORK, INFO)
           ZSYEQUB

Function/Subroutine Documentation
   subroutine zsyequb (character UPLO, integer N, complex*16, dimension( lda,
       * ) A, integer LDA, double precision, dimension( * ) S, double
       precision SCOND, double precision AMAX, complex*16, dimension( * )
```

```
      WORK, integer INFO)
      ZSYEQUB

Purpose:
   ZSYEQUB computes row and column scalings intended to equilibrate a
   symmetric matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The N-by-N symmetric matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is DOUBLE PRECISION array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is DOUBLE PRECISION
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix
   should be scaled.
```

```
 WORK
   WORK is COMPLEX*16 array, dimension (3*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsyrfs (UPLO, N, NRHS, A, LDA, AF, LDAF, IPIV, B, LDB, X,
           LDX, FERR, BERR, WORK, RWORK, INFO)
           ZSYRFS

Function/Subroutine Documentation
   subroutine zsyrfs (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldaf, * )
       AF, integer LDAF, integer, dimension( * ) IPIV, complex*16, dimension(
       ldb, * ) B, integer LDB, complex*16, dimension( ldx, * ) X, integer
       LDX, double precision, dimension( * ) FERR, double precision,
       dimension( * ) BERR, complex*16, dimension( * ) WORK, double precision,
       dimension( * ) RWORK, integer INFO)
       ZSYRFS

Purpose:
   ZSYRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.
```

```
A
  A is COMPLEX*16 array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The factored form of the matrix A.  AF contains the block
  diagonal matrix D and the multipliers used to obtain the
  factor U or L from the factorization A = U*D*U**T or
  A = L*D*L**T as computed by ZSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by ZSYTRF.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZSYTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
```

```
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

       double precision, dimension( * ) PARAMS, complex*16, dimension( * )
       WORK, double precision, dimension( * ) RWORK, integer INFO)
       ZSYRFSX

Purpose:
   ZSYRFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric indefinite, and
   provides error bounds and backward error estimates for the
   solution.  In addition to normwise error bound, the code provides
   maximum componentwise error bound if possible.  See comments for
   ERR_BNDS_NORM and ERR_BNDS_COMP for details of the error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
```

```
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular
   part of the matrix A, and the strictly lower triangular
   part of A is not referenced.  If UPLO = 'L', the leading
   N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The factored form of the matrix A.  AF contains the block
   diagonal matrix D and the multipliers used to obtain the
   factor U or L from the factorization A = U*D*U**T or A =
```

```
  L*D*L**T as computed by DSYTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D
  as determined by DSYTRF.

S
  S is DOUBLE PRECISION array, dimension (N)
  The scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.
```

```
BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                    max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * dlamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * dlamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
```

```
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * dlamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * dlamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.
```

```
NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
```

```
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine zsytf2 (UPLO, N, A, LDA, IPIV, INFO)
           ZSYTF2 computes the factorization of a real symmetric indefinite
           matrix, using the diagonal pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine zsytf2 (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       ZSYTF2 computes the factorization of a real symmetric indefinite
       matrix, using the diagonal pivoting method (unblocked algorithm).

Purpose:
   ZSYTF2 computes the factorization of a complex symmetric matrix A
   using the Bunch-Kaufman diagonal pivoting method:
```

```
   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, U**T is the transpose of U, and D is symmetric and
   block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k-1) < 0, then rows and columns
     k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
     is a 2-by-2 diagonal block.
```

```
   If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k) were
     interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) = IPIV(k+1) < 0, then rows and columns
     k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1)
     is a 2-by-2 diagonal block.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
              U(k) =   (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
              L(k) =   (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
```

```
If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zsytf2_rook (UPLO, N, A, LDA, IPIV, INFO)
           ZSYTF2_ROOK computes the factorization of a complex symmetric
           indefinite matrix using the bounded Bunch-Kaufman ('rook') diagonal
           pivoting method (unblocked algorithm).

Function/Subroutine Documentation
   subroutine zsytf2_rook (character UPLO, integer N, complex*16, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, integer INFO)
       ZSYTF2_ROOK computes the factorization of a complex symmetric
       indefinite matrix using the bounded Bunch-Kaufman ('rook') diagonal
       pivoting method (unblocked algorithm).

Purpose:
   ZSYTF2_ROOK computes the factorization of a complex symmetric matrix A
```

```
  using the bounded Bunch-Kaufman ("rook") diagonal pivoting method:

  A = U*D*U**T  or  A = L*D*L**T

  where U (or L) is a product of permutation and unit upper (lower)
  triangular matrices, U**T is the transpose of U, and D is symmetric and
  block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

  This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored:
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n-by-n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n-by-n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D.

   If UPLO = 'U':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
```

```
     columns k-1 and -IPIV(k-1) were inerchaged,
     D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

   If UPLO = 'L':
     If IPIV(k) > 0, then rows and columns k and IPIV(k)
     were interchanged and D(k,k) is a 1-by-1 diagonal block.

     If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
     columns k and -IPIV(k) were interchanged and rows and
     columns k+1 and -IPIV(k+1) were inerchaged,
     D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, D(k,k) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
     U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                        (   I    v    0   )   k-s
                U(k) =  (   0    I    0   )   s
                        (   0    0    I   )   n-k
                           k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                        (   I    0     0   )  k-1
                L(k) =  (   0    I     0   )  s
```

```
                    (   0    v     I   )  n-k-s+1
                       k-1   s  n-k-s+1

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).
```

```
SYNOPSIS
   Functions/Subroutines
       subroutine zsytrf (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           ZSYTRF

Function/Subroutine Documentation
   subroutine zsytrf (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, complex*16, dimension(
       * ) WORK, integer LWORK, integer INFO)
       ZSYTRF

Purpose:
   ZSYTRF computes the factorization of a complex symmetric matrix A
   using the Bunch-Kaufman diagonal pivoting method.  The form of the
   factorization is

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   with 1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, the block diagonal matrix D and the multipliers used
   to obtain the factor U or L (see below for further details).

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.
  If IPIV(k) > 0, then rows and columns k and IPIV(k) were
  interchanged and D(k,k) is a 1-by-1 diagonal block.
  If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and
  columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k)
  is a 2-by-2 diagonal block.  If UPLO = 'L' and IPIV(k) =
  IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were
  interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
     has been completed, but the block diagonal matrix D is
     exactly singular, and division by zero will occur if it
     is used to solve a system of equations.

Further Details:

  If UPLO = 'U', then A = U*D*U**T, where
     U = P(n)*U(n)* ... *P(k)U(k)* ...,
  i.e., U is a product of terms P(k)*U(k), where k decreases from n to
  1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
  and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
  defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
  that if the diagonal block D(k) is of order s (s = 1 or 2), then

                     (   I    v    0   )   k-s
             U(k) =  (   0    I    0   )   s
                     (   0    0    I   )   n-k
```

```
                        k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine zsytrf_rook (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           ZSYTRF_ROOK

Function/Subroutine Documentation
   subroutine zsytrf_rook (character UPLO, integer N, complex*16, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, complex*16,
       dimension( * ) WORK, integer LWORK, integer INFO)
       ZSYTRF_ROOK

Purpose:
   ZSYTRF_ROOK computes the factorization of a complex symmetric matrix A
   using the bounded Bunch-Kaufman ("rook") diagonal pivoting method.
   The form of the factorization is

   A = U*D*U**T  or  A = L*D*L**T

   where U (or L) is a product of permutation and unit upper (lower)
   triangular matrices, and D is symmetric and block diagonal with
   1-by-1 and 2-by-2 diagonal blocks.

   This is the blocked version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
```

```
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, the block diagonal matrix D and the multipliers used
  to obtain the factor U or L (see below for further details).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

IPIV
  IPIV is INTEGER array, dimension (N)
  Details of the interchanges and the block structure of D.

  If UPLO = 'U':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k-1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k-1 and -IPIV(k-1) were inerchaged,
    D(k-1:k,k-1:k) is a 2-by-2 diagonal block.

  If UPLO = 'L':
    If IPIV(k) > 0, then rows and columns k and IPIV(k)
    were interchanged and D(k,k) is a 1-by-1 diagonal block.

    If IPIV(k) < 0 and IPIV(k+1) < 0, then rows and
    columns k and -IPIV(k) were interchanged and rows and
    columns k+1 and -IPIV(k+1) were inerchaged,
    D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK
  WORK is COMPLEX*16 array, dimension (MAX(1,LWORK)).
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK
  LWORK is INTEGER
  The length of WORK.  LWORK >=1.  For best performance
  LWORK >= N*NB, where NB is the block size returned by ILAENV.

  If LWORK = -1, then a workspace query is assumed; the routine
  only calculates the optimal size of the WORK array, returns
  this value as the first entry of the WORK array, and no error
  message related to LWORK is issued by XERBLA.
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, D(i,i) is exactly zero.  The factorization
      has been completed, but the block diagonal matrix D is
      exactly singular, and division by zero will occur if it
      is used to solve a system of equations.

Further Details:

   If UPLO = 'U', then A = U*D*U**T, where
      U = P(n)*U(n)* ... *P(k)U(k)* ...,
   i.e., U is a product of terms P(k)*U(k), where k decreases from n to
   1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and U(k) is a unit upper triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    v    0   )   k-s
             U(k) =    (   0    I    0   )   s
                       (   0    0    I   )   n-k
                          k-s   s   n-k

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k).
   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k),
   and A(k,k), and v overwrites A(1:k-2,k-1:k).

   If UPLO = 'L', then A = L*D*L**T, where
      L = P(1)*L(1)* ... *P(k)*L(k)* ...,
   i.e., L is a product of terms P(k)*L(k), where k increases from 1 to
   n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1
   and 2-by-2 diagonal blocks D(k).  P(k) is a permutation matrix as
   defined by IPIV(k), and L(k) is a unit lower triangular matrix, such
   that if the diagonal block D(k) is of order s (s = 1 or 2), then

                       (   I    0     0   )  k-1
             L(k) =    (   0    I     0   )  s
                       (   0    v     I   )  n-k-s+1
                          k-1   s  n-k-s+1

   If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k).
   If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k),
   and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

SYNOPSIS
   Functions/Subroutines
       subroutine zsytri (UPLO, N, A, LDA, IPIV, WORK, INFO)
           ZSYTRI

Function/Subroutine Documentation
   subroutine zsytri (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer, dimension( * ) IPIV, complex*16, dimension(
```

```
      * ) WORK, integer INFO)
      ZSYTRI

Purpose:
   ZSYTRI computes the inverse of a complex symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by ZSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by ZSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF.

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsytri2 (UPLO, N, A, LDA, IPIV, WORK, LWORK, INFO)
           ZSYTRI2

Function/Subroutine Documentation
   subroutine zsytri2 (character UPLO, integer N, complex*16, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, complex*16,
       dimension( * ) WORK, integer LWORK, integer INFO)
       ZSYTRI2

Purpose:
   ZSYTRI2 computes the inverse of a COMPLEX*16 symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by
   ZSYTRF. ZSYTRI2 sets the LEADING DIMENSION of the workspace
   before calling ZSYTRI2X that actually computes the inverse.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the NB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by ZSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the NB structure of D
   as determined by ZSYTRF.

 WORK
   WORK is COMPLEX*16 array, dimension (N+NB+1)*(NB+3)

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK.
   WORK is size >= (N+NB+1)*(NB+3)
   If LDWORK = -1, then a workspace query is assumed; the routine
   calculates:
   - the optimal size of the WORK array, returns
   this value as the first entry of the WORK array,
   - and no error message related to LDWORK is issued by XERBLA.

 INFO
   INFO is INTEGER
```

```
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
     inverse could not be computed.

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine zsytri2x (UPLO, N, A, LDA, IPIV, WORK, NB, INFO)
          ZSYTRI2X

Function/Subroutine Documentation
   subroutine zsytri2x (character UPLO, integer N, complex*16, dimension( lda,
       * ) A, integer LDA, integer, dimension( * ) IPIV, complex*16,
       dimension( n+nb+1,* ) WORK, integer NB, integer INFO)
       ZSYTRI2X

Purpose:
   ZSYTRI2X computes the inverse of a complex symmetric indefinite matrix
   A using the factorization A = U*D*U**T or A = L*D*L**T computed by ZSYTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the NNB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by ZSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the NNB structure of D
   as determined by ZSYTRF.

 WORK
   WORK is COMPLEX*16 array, dimension (N+NNB+1,NNB+3)
```

```
 NB
   NB is INTEGER
   Block size

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
```

```
       subroutine zsytri_rook (UPLO, N, A, LDA, IPIV, WORK, INFO)
           ZSYTRI_ROOK

Function/Subroutine Documentation
   subroutine zsytri_rook (character UPLO, integer N, complex*16, dimension(
       lda, * ) A, integer LDA, integer, dimension( * ) IPIV, complex*16,
       dimension( * ) WORK, integer INFO)
       ZSYTRI_ROOK

Purpose:
   ZSYTRI_ROOK computes the inverse of a complex symmetric
   matrix A using the factorization A = U*D*U**T or A = L*D*L**T
   computed by ZSYTRF_ROOK.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the block diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by ZSYTRF_ROOK.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF_ROOK.

 WORK
   WORK is COMPLEX*16 array, dimension (N)
```

```
 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -i, the i-th argument had an illegal value
   > 0: if INFO = i, D(i,i) = 0; the matrix is singular and its
        inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsytrs (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           ZSYTRS

Function/Subroutine Documentation
   subroutine zsytrs (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB, integer INFO)
       ZSYTRS

Purpose:
   ZSYTRS solves a system of linear equations A*X = B with a complex
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by ZSYTRF.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF.

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zsytrs2 (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, INFO)
           ZSYTRS2

Function/Subroutine Documentation
   subroutine zsytrs2 (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB, complex*16, dimension(
       * ) WORK, integer INFO)
```

```
      ZSYTRS2

Purpose:
   ZSYTRS2 solves a system of linear equations A*X = B with a real
   symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by ZSYTRF and converted by ZSYCONV.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF.
   Note that A is input / output. This might be counter-intuitive,
   and one may think that A is input only. A is input / output. This
   is because, at the start of the subroutine, we permute A in a
   "better" form and then we permute A back to its original form at the end.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF.

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
```

```
  The leading dimension of the array B.  LDB >= max(1,N).

 WORK
  WORK is REAL array, dimension (N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zsytrs_rook (UPLO, N, NRHS, A, LDA, IPIV, B, LDB, INFO)
           ZSYTRS_ROOK

Function/Subroutine Documentation
   subroutine zsytrs_rook (character UPLO, integer N, integer NRHS,
       complex*16, dimension( lda, * ) A, integer LDA, integer, dimension( * )
       IPIV, complex*16, dimension( ldb, * ) B, integer LDB, integer INFO)
       ZSYTRS_ROOK

Purpose:
   ZSYTRS_ROOK solves a system of linear equations A*X = B with
   a complex symmetric matrix A using the factorization A = U*D*U**T or
   A = L*D*L**T computed by ZSYTRF_ROOK.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The block diagonal matrix D and the multipliers used to
   obtain the factor U or L as computed by ZSYTRF_ROOK.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 IPIV
   IPIV is INTEGER array, dimension (N)
   Details of the interchanges and the block structure of D
   as determined by ZSYTRF_ROOK.

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine ztgsyl (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, DIF, WORK, LWORK, IWORK, INFO)
           ZTGSYL

Function/Subroutine Documentation
```

```
   subroutine ztgsyl (character TRANS, integer IJOB, integer M, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldb, * ) B, integer LDB, complex*16, dimension( ldc, * ) C, integer
       LDC, complex*16, dimension( ldd, * ) D, integer LDD, complex*16,
       dimension( lde, * ) E, integer LDE, complex*16, dimension( ldf, * ) F,
       integer LDF, double precision SCALE, double precision DIF, complex*16,
       dimension( * ) WORK, integer LWORK, integer, dimension( * ) IWORK,
       integer INFO)
       ZTGSYL

Purpose:
   ZTGSYL solves the generalized Sylvester equation:

                   A * R - L * B = scale * C            (1)
                   D * R - L * E = scale * F

   where R and L are unknown m-by-n matrices, (A, D), (B, E) and
   (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n,
   respectively, with complex entries. A, B, D and E are upper
   triangular (i.e., (A,D) and (B,E) in generalized Schur form).

   The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1
   is an output scaling factor chosen to avoid overflow.

   In matrix notation (1) is equivalent to solve Zx = scale*b, where Z
   is defined as

              Z = [ kron(In, A)  -kron(B**H, Im) ]        (2)
                  [ kron(In, D)  -kron(E**H, Im) ],

   Here Ix is the identity matrix of size x and X**H is the conjugate
   transpose of X. Kron(X, Y) is the Kronecker product between the
   matrices X and Y.

   If TRANS = 'C', y in the conjugate transposed system Z**H *y = scale*b
   is solved for, which is equivalent to solve for R and L in

                   A**H * R + D**H * L = scale * C           (3)
                   R * B**H + L * E**H = scale * -F

   This case (TRANS = 'C') is used to compute an one-norm-based estimate
   of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D)
   and (B,E), using ZLACON.

   If IJOB >= 1, ZTGSYL computes a Frobenius norm-based estimate of
   Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the
   reciprocal of the smallest singular value of Z.

   This is a level-3 BLAS algorithm.
```

```
Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N': solve the generalized sylvester equation (1).
   = 'C': solve the "conjugate transposed" system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   =0: solve (1) only.
   =1: The functionality of 0 and 3.
   =2: The functionality of 0 and 4.
   =3: Only an estimate of Dif[(A,D), (B,E)] is computed.
       (look ahead strategy is used).
   =4: Only an estimate of Dif[(A,D), (B,E)] is computed.
       (ZGECON on sub-systems is used).
   Not referenced if TRANS = 'C'.

 M
   M is INTEGER
   The order of the matrices A and D, and the row dimension of
   the matrices C, F, R and L.

 N
   N is INTEGER
   The order of the matrices B and E, and the column dimension
   of the matrices C, F, R and L.

 A
   A is COMPLEX*16 array, dimension (LDA, M)
   The upper triangular matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1, M).

 B
   B is COMPLEX*16 array, dimension (LDB, N)
   The upper triangular matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B. LDB >= max(1, N).

 C
   C is COMPLEX*16 array, dimension (LDC, N)
   On entry, C contains the right-hand-side of the first matrix
   equation in (1) or (3).
   On exit, if IJOB = 0, 1 or 2, C has been overwritten by
```

```
  the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R,
  the solution achieved during the computation of the Dif-estimate.

LDC
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1, M).

D
  D is COMPLEX*16 array, dimension (LDD, M)
  The upper triangular matrix D.

LDD
  LDD is INTEGER
  The leading dimension of the array D. LDD >= max(1, M).

E
  E is COMPLEX*16 array, dimension (LDE, N)
  The upper triangular matrix E.

LDE
  LDE is INTEGER
  The leading dimension of the array E. LDE >= max(1, N).

F
  F is COMPLEX*16 array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1) or (3).
  On exit, if IJOB = 0, 1 or 2, F has been overwritten by
  the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L,
  the solution achieved during the computation of the Dif-estimate.

LDF
  LDF is INTEGER
  The leading dimension of the array F. LDF >= max(1, M).

DIF
  DIF is DOUBLE PRECISION
  On exit DIF is the reciprocal of a lower bound of the
  reciprocal of the Dif-function, i.e. DIF is an upper bound of
  Dif[(A,D), (B,E)] = sigma-min(Z), where Z as in (2).
  IF IJOB = 0 or TRANS = 'C', DIF is not referenced.

SCALE
  SCALE is DOUBLE PRECISION
  On exit SCALE is the scaling factor in (1) or (3).
  If 0 < SCALE < 1, C and F hold the solutions R and L, resp.,
  to a slightly perturbed system but the input matrices A, B,
  D and E have not been changed. If SCALE = 0, R and L will
  hold the solutions to the homogenious system with C = F = 0.
```

```
 WORK
   WORK is COMPLEX*16 array, dimension (MAX(1,LWORK))
   On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK
   LWORK is INTEGER
   The dimension of the array WORK. LWORK > = 1.
   If IJOB = 1 or 2 and TRANS = 'N', LWORK >= max(1,2*M*N).

   If LWORK = -1, then a workspace query is assumed; the routine
   only calculates the optimal size of the WORK array, returns
   this value as the first entry of the WORK array, and no error
   message related to LWORK is issued by XERBLA.

 IWORK
   IWORK is INTEGER array, dimension (M+N+2)

 INFO
   INFO is INTEGER
   =0: successful exit
   <0: If INFO = -i, the i-th argument had an illegal value.
   >0: (A, D) and (B, E) have common or very close eigenvalues.
```

SYNOPSIS
   Functions/Subroutines
       subroutine ztrsyl (TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
           SCALE, INFO)
           ZTRSYL

Function/Subroutine Documentation
   subroutine ztrsyl (character TRANA, character TRANB, integer ISGN, integer
       M, integer N, complex*16, dimension( lda, * ) A, integer LDA,
       complex*16, dimension( ldb, * ) B, integer LDB, complex*16, dimension(
       ldc, * ) C, integer LDC, double precision SCALE, integer INFO)
       ZTRSYL

Purpose:
   ZTRSYL solves the complex Sylvester matrix equation:

   op(A)*X + X*op(B) = scale*C or
   op(A)*X - X*op(B) = scale*C,

   where op(A) = A or A**H, and A and B are both upper triangular. A is
   M-by-M and B is N-by-N; the right hand side C and the solution X are
   M-by-N; and scale is an output scale factor, set <= 1 to avoid
   overflow in X.

Parameters:
```

```
TRANA
  TRANA is CHARACTER*1
  Specifies the option op(A):
  = 'N': op(A) = A    (No transpose)
  = 'C': op(A) = A**H (Conjugate transpose)

TRANB
  TRANB is CHARACTER*1
  Specifies the option op(B):
  = 'N': op(B) = B    (No transpose)
  = 'C': op(B) = B**H (Conjugate transpose)

ISGN
  ISGN is INTEGER
  Specifies the sign in the equation:
  = +1: solve op(A)*X + X*op(B) = scale*C
  = -1: solve op(A)*X - X*op(B) = scale*C

M
  M is INTEGER
  The order of the matrix A, and the number of rows in the
  matrices X and C. M >= 0.

N
  N is INTEGER
  The order of the matrix B, and the number of columns in the
  matrices X and C. N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,M)
  The upper triangular matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A. LDA >= max(1,M).

B
  B is COMPLEX*16 array, dimension (LDB,N)
  The upper triangular matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B. LDB >= max(1,N).

C
  C is COMPLEX*16 array, dimension (LDC,N)
  On entry, the M-by-N right hand side matrix C.
  On exit, C is overwritten by the solution matrix X.

LDC
```

```
  LDC is INTEGER
  The leading dimension of the array C. LDC >= max(1,M)

 SCALE
  SCALE is DOUBLE PRECISION
  The scale factor, scale, set <= 1 to avoid overflow in X.

 INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  = 1: A and B have common or very close eigenvalues; perturbed
       values were used to solve the equation (but the matrices
       A and B are unchanged).
```

SYNOPSIS
   Functions/Subroutines
       double precision function dlansy (NORM, UPLO, N, A, LDA, WORK)
           DLANSY returns the value of the 1-norm, or the Frobenius norm, or
           the infinity norm, or the element of largest absolute value of a
           real symmetric matrix.

Function/Subroutine Documentation
   double precision function dlansy (character NORM, character UPLO, integer
       N, double precision, dimension( lda, * ) A, integer LDA, double
       precision, dimension( * ) WORK)
       DLANSY returns the value of the 1-norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a real
       symmetric matrix.

Purpose:
   DLANSY  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   real symmetric matrix A.

 Returns:

   DLANSY

       DLANSY = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                 ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in DLANSY as described above.

 UPLO
   UPLO is CHARACTER*1
```

```
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is to be referenced.
  = 'U':  Upper triangular part of A is referenced
  = 'L':  Lower triangular part of A is referenced

N
  N is INTEGER
  The order of the matrix A.  N >= 0.  When N = 0, DLANSY is set to zero.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading n by n
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading n by n lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(N,1).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise,
  WORK is not referenced.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dlaqsy (UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
           DLAQSY scales a symmetric/Hermitian matrix, using scaling factors
           computed by spoequ.

Function/Subroutine Documentation
   subroutine dlaqsy (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision, dimension( * ) S, double
       precision SCOND, double precision AMAX, character EQUED)
       DLAQSY scales a symmetric/Hermitian matrix, using scaling factors
       computed by spoequ.

Purpose:
   DLAQSY equilibrates a symmetric matrix A using the scaling factors
   in the vector S.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n by n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if EQUED = 'Y', the equilibrated matrix:
   diag(S) * A * diag(S).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(N,1).
```

```
 S
   S is DOUBLE PRECISION array, dimension (N)
   The scale factors for A.

 SCOND
   SCOND is DOUBLE PRECISION
   Ratio of the smallest S(i) to the largest S(i).

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies whether or not equilibration was done.
   = 'N':  No equilibration.
   = 'Y':  Equilibration was done, i.e., A has been replaced by
   diag(S) * A * diag(S).

Internal Parameters:

   THRESH is a threshold value used to decide if scaling should be done
   based on the ratio of the scaling factors.  If SCOND < THRESH,
   scaling is done.

   LARGE and SMALL are threshold values used to decide if scaling should
   be done based on the absolute size of the largest matrix element.
   If AMAX > LARGE or AMAX < SMALL, scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasy2 (LTRANL, LTRANR, ISGN, N1, N2, TL, LDTL, TR, LDTR, B,
           LDB, SCALE, X, LDX, XNORM, INFO)
           DLASY2 solves the Sylvester matrix equation where the matrices are
           of order 1 or 2.

Function/Subroutine Documentation
   subroutine dlasy2 (logical LTRANL, logical LTRANR, integer ISGN, integer
       N1, integer N2, double precision, dimension( ldtl, * ) TL, integer
       LDTL, double precision, dimension( ldtr, * ) TR, integer LDTR, double
       precision, dimension( ldb, * ) B, integer LDB, double precision SCALE,
       double precision, dimension( ldx, * ) X, integer LDX, double precision
       XNORM, integer INFO)
       DLASY2 solves the Sylvester matrix equation where the matrices are of
       order 1 or 2.

Purpose:
   DLASY2 solves for the N1 by N2 matrix X, 1 <= N1,N2 <= 2, in

   op(TL)*X + ISGN*X*op(TR) = SCALE*B,

   where TL is N1 by N1, TR is N2 by N2, B is N1 by N2, and ISGN = 1 or -1.
   op(T) = T or T**T, where T**T denotes the transpose of T.

Parameters:

 LTRANL
   LTRANL is LOGICAL
   On entry, LTRANL specifies the op(TL):
   = .FALSE., op(TL) = TL,
   = .TRUE., op(TL) = TL**T.

 LTRANR
   LTRANR is LOGICAL
   On entry, LTRANR specifies the op(TR):
   = .FALSE., op(TR) = TR,
   = .TRUE., op(TR) = TR**T.

 ISGN
   ISGN is INTEGER
   On entry, ISGN specifies the sign of the equation
```

```
  as described before. ISGN may only be 1 or -1.

N1
  N1 is INTEGER
  On entry, N1 specifies the order of matrix TL.
  N1 may only be 0, 1 or 2.

N2
  N2 is INTEGER
  On entry, N2 specifies the order of matrix TR.
  N2 may only be 0, 1 or 2.

TL
  TL is DOUBLE PRECISION array, dimension (LDTL,2)
  On entry, TL contains an N1 by N1 matrix.

LDTL
  LDTL is INTEGER
  The leading dimension of the matrix TL. LDTL >= max(1,N1).

TR
  TR is DOUBLE PRECISION array, dimension (LDTR,2)
  On entry, TR contains an N2 by N2 matrix.

LDTR
  LDTR is INTEGER
  The leading dimension of the matrix TR. LDTR >= max(1,N2).

B
  B is DOUBLE PRECISION array, dimension (LDB,2)
  On entry, the N1 by N2 matrix B contains the right-hand
  side of the equation.

LDB
  LDB is INTEGER
  The leading dimension of the matrix B. LDB >= max(1,N1).

SCALE
  SCALE is DOUBLE PRECISION
  On exit, SCALE contains the scale factor. SCALE is chosen
  less than or equal to 1 to prevent the solution overflowing.

X
  X is DOUBLE PRECISION array, dimension (LDX,2)
  On exit, X contains the N1 by N2 solution.

LDX
  LDX is INTEGER
  The leading dimension of the matrix X. LDX >= max(1,N1).
```

```
 XNORM
   XNORM is DOUBLE PRECISION
   On exit, XNORM is the infinity-norm of the solution.

 INFO
   INFO is INTEGER
   On exit, INFO is set to
   0: successful exit.
   1: TL and TR have too close eigenvalues, so TL or
      TR is perturbed to get a nonsingular equation.
   NOTE: In the interests of speed, this routine does not
   check the inputs for errors.

SYNOPSIS
   Functions/Subroutines
       subroutine dsyswapr (UPLO, N, A, LDA, I1, I2)
           DSYSWAPR applies an elementary permutation on the rows and columns
           of a symmetric matrix.

Function/Subroutine Documentation
   subroutine dsyswapr (character UPLO, integer N, double precision,
       dimension( lda, n ) A, integer LDA, integer I1, integer I2)
       DSYSWAPR applies an elementary permutation on the rows and columns of a
       symmetric matrix.

Purpose:
   DSYSWAPR applies an elementary permutation on the rows and the columns of
   a symmetric matrix.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the NB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by DSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 I1
   I1 is INTEGER
   Index of the first row to swap

 I2
   I2 is INTEGER
   Index of the second row to swap
```

       double precision, dimension( lde, * ) E, integer LDE, double precision,
       dimension( ldf, * ) F, integer LDF, double precision SCALE, double
       precision RDSUM, double precision RDSCAL, integer, dimension( * )
       IWORK, integer PQ, integer INFO)
```

```
      DTGSY2 solves the generalized Sylvester equation (unblocked algorithm).

Purpose:
   DTGSY2 solves the generalized Sylvester equation:

   A * R - L * B = scale * C                (1)
   D * R - L * E = scale * F,

   using Level 1 and 2 BLAS. where R and L are unknown M-by-N matrices,
   (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M,
   N-by-N and M-by-N, respectively, with real entries. (A, D) and (B, E)
   must be in generalized Schur canonical form, i.e. A, B are upper
   quasi triangular and D, E are upper triangular. The solution (R, L)
   overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor
   chosen to avoid overflow.

   In matrix notation solving equation (1) corresponds to solve
   Z*x = scale*b, where Z is defined as

      Z = [ kron(In, A)  -kron(B**T, Im) ]             (2)
          [ kron(In, D)  -kron(E**T, Im) ],

   Ik is the identity matrix of size k and X**T is the transpose of X.
   kron(X, Y) is the Kronecker product between the matrices X and Y.
   In the process of solving (1), we solve a number of such systems
   where Dim(In), Dim(In) = 1 or 2.

   If TRANS = 'T', solve the transposed system Z**T*y = scale*b for y,
   which is equivalent to solve for R and L in

      A**T * R  + D**T * L   = scale * C           (3)
      R  * B**T + L  * E**T  = scale * -F

   This case is used to compute an estimate of Dif[(A, D), (B, E)] =
   sigma_min(Z) using reverse communicaton with DLACON.

   DTGSY2 also (IJOB >= 1) contributes to the computation in DTGSYL
   of an upper bound on the separation between to matrix pairs. Then
   the input (A, D), (B, E) are sub-pencils of the matrix pair in
   DTGSYL. See DTGSYL for details.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N', solve the generalized Sylvester equation (1).
   = 'T': solve the 'transposed' system (3).

 IJOB
   IJOB is INTEGER
```

```
  Specifies what kind of functionality to be performed.
  = 0: solve (1) only.
  = 1: A contribution from this subsystem to a Frobenius
       norm-based estimate of the separation between two matrix
       pairs is computed. (look ahead strategy is used).
  = 2: A contribution from this subsystem to a Frobenius
       norm-based estimate of the separation between two matrix
       pairs is computed. (DGECON on sub-systems is used.)
  Not referenced if TRANS = 'T'.

M
  M is INTEGER
  On entry, M specifies the order of A and D, and the row
  dimension of C, F, R and L.

N
  N is INTEGER
  On entry, N specifies the order of B and E, and the column
  dimension of C, F, R and L.

A
  A is DOUBLE PRECISION array, dimension (LDA, M)
  On entry, A contains an upper quasi triangular matrix.

LDA
  LDA is INTEGER
  The leading dimension of the matrix A. LDA >= max(1, M).

B
  B is DOUBLE PRECISION array, dimension (LDB, N)
  On entry, B contains an upper quasi triangular matrix.

LDB
  LDB is INTEGER
  The leading dimension of the matrix B. LDB >= max(1, N).

C
  C is DOUBLE PRECISION array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1).
  On exit, if IJOB = 0, C has been overwritten by the
  solution R.

LDC
  LDC is INTEGER
  The leading dimension of the matrix C. LDC >= max(1, M).

D
  D is DOUBLE PRECISION array, dimension (LDD, M)
  On entry, D contains an upper triangular matrix.
```

```
LDD
  LDD is INTEGER
  The leading dimension of the matrix D. LDD >= max(1, M).

E
  E is DOUBLE PRECISION array, dimension (LDE, N)
  On entry, E contains an upper triangular matrix.

LDE
  LDE is INTEGER
  The leading dimension of the matrix E. LDE >= max(1, N).

F
  F is DOUBLE PRECISION array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1).
  On exit, if IJOB = 0, F has been overwritten by the
  solution L.

LDF
  LDF is INTEGER
  The leading dimension of the matrix F. LDF >= max(1, M).

SCALE
  SCALE is DOUBLE PRECISION
  On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions
  R and L (C and F on entry) will hold the solutions to a
  slightly perturbed system but the input matrices A, B, D and
  E have not been changed. If SCALE = 0, R and L will hold the
  solutions to the homogeneous system with C = F = 0. Normally, SCALE = 1.

RDSUM
  RDSUM is DOUBLE PRECISION
  On entry, the sum of squares of computed contributions to
  the Dif-estimate under computation by DTGSYL, where the
  scaling factor RDSCAL (see below) has been factored out.
  On exit, the corresponding sum of squares updated with the
  contributions from the current sub-system.
  If TRANS = 'T' RDSUM is not touched.
  NOTE: RDSUM only makes sense when DTGSY2 is called by DTGSYL.

RDSCAL
  RDSCAL is DOUBLE PRECISION
  On entry, scaling factor used to prevent overflow in RDSUM.
  On exit, RDSCAL is updated w.r.t. the current contributions
  in RDSUM.
  If TRANS = 'T', RDSCAL is not touched.
  NOTE: RDSCAL only makes sense when DTGSY2 is called by DTGSYL.
```

```
 IWORK
   IWORK is INTEGER array, dimension (M+N+2)

 PQ
   PQ is INTEGER
   On exit, the number of subsystems (of size 2-by-2, 4-by-4 and
   8-by-8) solved by this routine.

 INFO
   INFO is INTEGER
   On exit, if INFO is set to
   =0: Successful exit
   <0: If INFO = -i, the i-th argument had an illegal value.
   >0: The matrix pairs (A, D) and (B, E) have common or very
       close eigenvalues.
```

SYNOPSIS
   Functions/Subroutines
       real function slansy (NORM, UPLO, N, A, LDA, WORK)
           SLANSY returns the value of the 1-norm, or the Frobenius norm, or
           the infinity norm, or the element of largest absolute value of a
           real symmetric matrix.

Function/Subroutine Documentation
   real function slansy (character NORM, character UPLO, integer N, real,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) WORK)
       SLANSY returns the value of the 1-norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a real
       symmetric matrix.

Purpose:
   SLANSY  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   real symmetric matrix A.

 Returns:

   SLANSY

       SLANSY = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in SLANSY as described above.

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
```

```
  symmetric matrix A is to be referenced.
  = 'U':  Upper triangular part of A is referenced
  = 'L':  Lower triangular part of A is referenced

N
  N is INTEGER
  The order of the matrix A.  N >= 0.  When N = 0, SLANSY is set to zero.

A
  A is REAL array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading n by n
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading n by n lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(N,1).

WORK
  WORK is REAL array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise,
  WORK is not referenced.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slaqsy (UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
           SLAQSY scales a symmetric/Hermitian matrix, using scaling factors
           computed by spoequ.

Function/Subroutine Documentation
   subroutine slaqsy (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, real, dimension( * ) S, real SCOND, real AMAX, character
       EQUED)
       SLAQSY scales a symmetric/Hermitian matrix, using scaling factors
       computed by spoequ.

Purpose:
   SLAQSY equilibrates a symmetric matrix A using the scaling factors
   in the vector S.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n by n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if EQUED = 'Y', the equilibrated matrix:
   diag(S) * A * diag(S).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(N,1).

 S
   S is REAL array, dimension (N)
   The scale factors for A.

 SCOND
   SCOND is REAL
   Ratio of the smallest S(i) to the largest S(i).

 AMAX
   AMAX is REAL
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies whether or not equilibration was done.
   = 'N':  No equilibration.
   = 'Y':  Equilibration was done, i.e., A has been replaced by
           diag(S) * A * diag(S).
```

```
Internal Parameters:

   THRESH is a threshold value used to decide if scaling should be done
   based on the ratio of the scaling factors.  If SCOND < THRESH,
   scaling is done.

   LARGE and SMALL are threshold values used to decide if scaling should
   be done based on the absolute size of the largest matrix element.
   If AMAX > LARGE or AMAX < SMALL, scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasy2 (LTRANL, LTRANR, ISGN, N1, N2, TL, LDTL, TR, LDTR, B,
           LDB, SCALE, X, LDX, XNORM, INFO)
           SLASY2 solves the Sylvester matrix equation where the matrices are
           of order 1 or 2.

Function/Subroutine Documentation
   subroutine slasy2 (logical LTRANL, logical LTRANR, integer ISGN, integer
       N1, integer N2, real, dimension( ldtl, * ) TL, integer LDTL, real,
       dimension( ldtr, * ) TR, integer LDTR, real, dimension( ldb, * ) B,
       integer LDB, real SCALE, real, dimension( ldx, * ) X, integer LDX, real
```

```
       XNORM, integer INFO)
       SLASY2 solves the Sylvester matrix equation where the matrices are of
       order 1 or 2.

Purpose:
   SLASY2 solves for the N1 by N2 matrix X, 1 <= N1,N2 <= 2, in

   op(TL)*X + ISGN*X*op(TR) = SCALE*B,

   where TL is N1 by N1, TR is N2 by N2, B is N1 by N2, and ISGN = 1 or -1
   op(T) = T or T**T, where T**T denotes the transpose of T.

Parameters:

 LTRANL
   LTRANL is LOGICAL
   On entry, LTRANL specifies the op(TL):
   = .FALSE., op(TL) = TL,
   = .TRUE., op(TL) = TL**T.

 LTRANR
   LTRANR is LOGICAL
   On entry, LTRANR specifies the op(TR):
   = .FALSE., op(TR) = TR,
   = .TRUE., op(TR) = TR**T.

 ISGN
   ISGN is INTEGER
   On entry, ISGN specifies the sign of the equation
   as described before. ISGN may only be 1 or -1.

 N1
   N1 is INTEGER
   On entry, N1 specifies the order of matrix TL.
   N1 may only be 0, 1 or 2.

 N2
   N2 is INTEGER
   On entry, N2 specifies the order of matrix TR.
   N2 may only be 0, 1 or 2.

 TL
   TL is REAL array, dimension (LDTL,2)
   On entry, TL contains an N1 by N1 matrix.

 LDTL
   LDTL is INTEGER
   The leading dimension of the matrix TL. LDTL >= max(1,N1).

 TR
```

```
  TR is REAL array, dimension (LDTR,2)
  On entry, TR contains an N2 by N2 matrix.

LDTR
  LDTR is INTEGER
  The leading dimension of the matrix TR. LDTR >= max(1,N2).

B
  B is REAL array, dimension (LDB,2)
  On entry, the N1 by N2 matrix B contains the right-hand
  side of the equation.

LDB
  LDB is INTEGER
  The leading dimension of the matrix B. LDB >= max(1,N1).

SCALE
  SCALE is REAL
  On exit, SCALE contains the scale factor. SCALE is chosen
  less than or equal to 1 to prevent the solution overflowing.

X
  X is REAL array, dimension (LDX,2)
  On exit, X contains the N1 by N2 solution.

LDX
  LDX is INTEGER
  The leading dimension of the matrix X. LDX >= max(1,N1).

XNORM
  XNORM is REAL
  On exit, XNORM is the infinity-norm of the solution.

INFO
  INFO is INTEGER
  On exit, INFO is set to
    0: successful exit.
    1: TL and TR have too close eigenvalues, so TL or
       TR is perturbed to get a nonsingular equation.
  NOTE: In the interests of speed, this routine does not
  check the inputs for errors.

SYNOPSIS
   Functions/Subroutines
       subroutine ssyswapr (UPLO, N, A, LDA, I1, I2)
           SSYSWAPR applies an elementary permutation on the rows and columns
           of a symmetric matrix.

Function/Subroutine Documentation
   subroutine ssyswapr (character UPLO, integer N, real, dimension( lda, n )
       A, integer LDA, integer I1, integer I2)
       SSYSWAPR applies an elementary permutation on the rows and columns of a
       symmetric matrix.

Purpose:
   SSYSWAPR applies an elementary permutation on the rows and the columns of
   a symmetric matrix.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the NB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by SSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
   inverse is formed and the part of A below the diagonal is not
   referenced; if UPLO = 'L' the lower triangular part of the
   inverse is formed and the part of A above the diagonal is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 I1
   I1 is INTEGER
   Index of the first row to swap

 I2
   I2 is INTEGER
   Index of the second row to swap
```

Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine stgsy2 (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, RDSUM, RDSCAL, IWORK, PQ, INFO)
           STGSY2 solves the generalized Sylvester equation (unblocked
           algorithm).

Function/Subroutine Documentation
   subroutine stgsy2 (character TRANS, integer IJOB, integer M, integer N,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, real, dimension( ldc, * ) C, integer LDC, real, dimension(
       ldd, * ) D, integer LDD, real, dimension( lde, * ) E, integer LDE,
       real, dimension( ldf, * ) F, integer LDF, real SCALE, real RDSUM, real
       RDSCAL, integer, dimension( * ) IWORK, integer PQ, integer INFO)
       STGSY2 solves the generalized Sylvester equation (unblocked algorithm).
```

```
Purpose:
   STGSY2 solves the generalized Sylvester equation:

        A * R - L * B = scale * C                (1)
        D * R - L * E = scale * F,

   using Level 1 and 2 BLAS. where R and L are unknown M-by-N matrices,
   (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M,
   N-by-N and M-by-N, respectively, with real entries. (A, D) and (B, E)
   must be in generalized Schur canonical form, i.e. A, B are upper
   quasi triangular and D, E are upper triangular. The solution (R, L)
   overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor
   chosen to avoid overflow.

   In matrix notation solving equation (1) corresponds to solve
   Z*x = scale*b, where Z is defined as

        Z = [ kron(In, A)  -kron(B**T, Im) ]             (2)
            [ kron(In, D)  -kron(E**T, Im) ],

   Ik is the identity matrix of size k and X**T is the transpose of X.
   kron(X, Y) is the Kronecker product between the matrices X and Y.
   In the process of solving (1), we solve a number of such systems
   where Dim(In), Dim(In) = 1 or 2.

   If TRANS = 'T', solve the transposed system Z**T*y = scale*b for y,
   which is equivalent to solve for R and L in

        A**T * R  + D**T * L   = scale * C           (3)
        R  * B**T + L  * E**T  = scale * -F

   This case is used to compute an estimate of Dif[(A, D), (B, E)] =
   sigma_min(Z) using reverse communicaton with SLACON.

   STGSY2 also (IJOB >= 1) contributes to the computation in STGSYL
   of an upper bound on the separation between to matrix pairs. Then
   the input (A, D), (B, E) are sub-pencils of the matrix pair in
   STGSYL. See STGSYL for details.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N', solve the generalized Sylvester equation (1).
   = 'T': solve the 'transposed' system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   = 0: solve (1) only.
```

```
  = 1: A contribution from this subsystem to a Frobenius
     norm-based estimate of the separation between two matrix
     pairs is computed. (look ahead strategy is used).
  = 2: A contribution from this subsystem to a Frobenius
     norm-based estimate of the separation between two matrix
    pairs is computed. (SGECON on sub-systems is used.)
  Not referenced if TRANS = 'T'.

M
  M is INTEGER
  On entry, M specifies the order of A and D, and the row
  dimension of C, F, R and L.

N
  N is INTEGER
  On entry, N specifies the order of B and E, and the column
  dimension of C, F, R and L.

A
  A is REAL array, dimension (LDA, M)
  On entry, A contains an upper quasi triangular matrix.

LDA
  LDA is INTEGER
  The leading dimension of the matrix A. LDA >= max(1, M).

B
  B is REAL array, dimension (LDB, N)
  On entry, B contains an upper quasi triangular matrix.

LDB
  LDB is INTEGER
  The leading dimension of the matrix B. LDB >= max(1, N).

C
  C is REAL array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1).
  On exit, if IJOB = 0, C has been overwritten by the
  solution R.

LDC
  LDC is INTEGER
  The leading dimension of the matrix C. LDC >= max(1, M).

D
  D is REAL array, dimension (LDD, M)
  On entry, D contains an upper triangular matrix.

LDD
```

```
  LDD is INTEGER
  The leading dimension of the matrix D. LDD >= max(1, M).

E
  E is REAL array, dimension (LDE, N)
  On entry, E contains an upper triangular matrix.

LDE
  LDE is INTEGER
  The leading dimension of the matrix E. LDE >= max(1, N).

F
  F is REAL array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1).
  On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF
  LDF is INTEGER
  The leading dimension of the matrix F. LDF >= max(1, M).

SCALE
  SCALE is REAL
  On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions
  R and L (C and F on entry) will hold the solutions to a
  slightly perturbed system but the input matrices A, B, D and
  E have not been changed. If SCALE = 0, R and L will hold the
  solutions to the homogeneous system with C = F = 0. Normally, SCALE = 1.

RDSUM
  RDSUM is REAL
  On entry, the sum of squares of computed contributions to
  the Dif-estimate under computation by STGSYL, where the
  scaling factor RDSCAL (see below) has been factored out.
  On exit, the corresponding sum of squares updated with the
  contributions from the current sub-system.
  If TRANS = 'T' RDSUM is not touched.
  NOTE: RDSUM only makes sense when STGSY2 is called by STGSYL.

RDSCAL
  RDSCAL is REAL
  On entry, scaling factor used to prevent overflow in RDSUM.
  On exit, RDSCAL is updated w.r.t. the current contributions
  in RDSUM.
  If TRANS = 'T', RDSCAL is not touched.
  NOTE: RDSCAL only makes sense when STGSY2 is called by STGSYL.

IWORK
  IWORK is INTEGER array, dimension (M+N+2)
```

```
 PQ
   PQ is INTEGER
   On exit, the number of subsystems (of size 2-by-2, 4-by-4 and
   8-by-8) solved by this routine.

 INFO
   INFO is INTEGER
   On exit, if INFO is set to
   =0: Successful exit
   <0: If INFO = -i, the i-th argument had an illegal value.
   >0: The matrix pairs (A, D) and (B, E) have common or very
       close eigenvalues.

SYNOPSIS
   Functions/Subroutines
       subroutine claesy (A, B, C, RT1, RT2, EVSCAL, CS1, SN1)
           CLAESY computes the eigenvalues and eigenvectors of a 2-by-2
           complex symmetric matrix.

Function/Subroutine Documentation
   subroutine claesy (complex A, complex B, complex C, complex RT1, complex
       RT2, complex EVSCAL, complex CS1, complex SN1)
       CLAESY computes the eigenvalues and eigenvectors of a 2-by-2 complex
       symmetric matrix.

Purpose:
   CLAESY computes the eigendecomposition of a 2-by-2 symmetric matrix
        ( ( A, B );( B, C ) )
   provided the norm of the matrix of eigenvectors is larger than
   some threshold value.

   RT1 is the eigenvalue of larger absolute value, and RT2 of
   smaller absolute value.  If the eigenvectors are computed, then
   on return ( CS1, SN1 ) is the unit eigenvector for RT1, hence

         [  CS1     SN1   ] . [ A  B ] . [ CS1    -SN1   ] = [ RT1  0  ]
         [ -SN1     CS1   ]   [ B  C ]   [ SN1     CS1   ]   [  0  RT2 ]

Parameters:

 A
   A is COMPLEX
   The ( 1, 1 ) element of input matrix.

 B
   B is COMPLEX
   The ( 1, 2 ) element of input matrix.  The ( 2, 1 ) element
   is also given by B, since the 2-by-2 matrix is symmetric.

 C
   C is COMPLEX
   The ( 2, 2 ) element of input matrix.

 RT1
   RT1 is COMPLEX
   The eigenvalue of larger modulus.

 RT2
```

```
  RT2 is COMPLEX
  The eigenvalue of smaller modulus.

EVSCAL
  EVSCAL is COMPLEX
  The complex value by which the eigenvector matrix was scaled
  to make it orthonormal.  If EVSCAL is zero, the eigenvectors
  were not computed.  This means one of two things:  the 2-by-2
  matrix could not be diagonalized, or the norm of the matrix
  of eigenvectors before scaling was larger than the threshold
  value THRESH (set below).

CS1
  CS1 is COMPLEX

SN1
  SN1 is COMPLEX
  If EVSCAL .NE. 0,  ( CS1, SN1 ) is the unit right eigenvector
  for RT1.
```

SYNOPSIS
   Functions/Subroutines
       real function clansy (NORM, UPLO, N, A, LDA, WORK)
           CLANSY returns the value of the 1-norm, or the Frobenius norm, or
           the infinity norm, or the element of largest absolute value of a
           complex symmetric matrix.

Function/Subroutine Documentation
   real function clansy (character NORM, character UPLO, integer N, complex,
       dimension( lda, * ) A, integer LDA, real, dimension( * ) WORK)
       CLANSY returns the value of the 1-norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a complex
       symmetric matrix.

Purpose:
   CLANSY  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   complex symmetric matrix A.

 Returns:

   CLANSY

        CLANSY = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                 (
                 ( norm1(A),         NORM = '1', 'O' or 'o'
                 (
                 ( normI(A),         NORM = 'I' or 'i'
                 (
                 ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in CLANSY as described above.
```

```
 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is to be referenced.
   = 'U':  Upper triangular part of A is referenced
   = 'L':  Lower triangular part of A is referenced

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.  When N = 0, CLANSY is set to zero.

 A
   A is COMPLEX array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading n by n
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading n by n lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(N,1).

 WORK
   WORK is REAL array, dimension (MAX(1,LWORK)),
   where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise,
   WORK is not referenced.
```
