====================================================================

====================================================================
Man Page Details
====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine claqsy (UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
           CLAQSY scales a symmetric/Hermitian matrix, using scaling factors
           computed by spoequ.

Function/Subroutine Documentation
   subroutine claqsy (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, real, dimension( * ) S, real SCOND, real AMAX,
       character EQUED)
       CLAQSY scales a symmetric/Hermitian matrix, using scaling factors
       computed by spoequ.

Purpose:
   CLAQSY equilibrates a symmetric matrix A using the scaling factors
   in the vector S.

 Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n by n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if EQUED = 'Y', the equilibrated matrix:
   diag(S) * A * diag(S).
```

```
 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(N,1).

 S
   S is REAL array, dimension (N)
   The scale factors for A.

 SCOND
   SCOND is REAL
   Ratio of the smallest S(i) to the largest S(i).

 AMAX
   AMAX is REAL
   Absolute value of largest matrix entry.

 EQUED
   EQUED is CHARACTER*1
   Specifies whether or not equilibration was done.
   = 'N':  No equilibration.
   = 'Y':  Equilibration was done, i.e., A has been replaced by
           diag(S) * A * diag(S).

Internal Parameters:

   THRESH is a threshold value used to decide if scaling should be done
   based on the ratio of the scaling factors.  If SCOND < THRESH,
   scaling is done.

   LARGE and SMALL are threshold values used to decide if scaling should
   be done based on the absolute size of the largest matrix element.
   If AMAX > LARGE or AMAX < SMALL, scaling is done.
```

==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine csymv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           CSYMV computes a matrix-vector product for a complex symmetric
           matrix.

Function/Subroutine Documentation
   subroutine csymv (character UPLO, integer N, complex ALPHA, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( * ) X, integer
       INCX, complex BETA, complex, dimension( * ) Y, integer INCY)
       CSYMV computes a matrix-vector product for a complex symmetric matrix.

Purpose:
   CSYMV  performs the matrix-vector  operation

   y := alpha*A*x + beta*y,

   where alpha and beta are scalars, x and y are n element vectors and
   A is an n by n symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as
   follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.
   UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

   Unchanged on exit.

 N
   N is INTEGER
   On entry, N specifies the order of the matrix A.
   N must be at least zero.
```

```
  Unchanged on exit.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is COMPLEX array, dimension ( LDA, N )
  Before entry, with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the symmetric matrix and the strictly
  lower triangular part of A is not referenced.
  Before entry, with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the symmetric matrix and the strictly
  upper triangular part of A is not referenced.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, N ).
  Unchanged on exit.

X
  X is COMPLEX array, dimension at least ( 1 + ( N - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the N-element vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is COMPLEX
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.

Y
  Y is COMPLEX array, dimension at least
  ( 1 + ( N - 1 )*abs( INCY ) ).
  Before entry, the incremented array Y must contain the n
  element vector y. On exit, Y is overwritten by the updated vector y.

INCY
  INCY is INTEGER
```

```
On entry, INCY specifies the increment for the elements of
Y. INCY must not be zero.
Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       subroutine csyr (UPLO, N, ALPHA, X, INCX, A, LDA)
           CSYR performs the symmetric rank-1 update of a complex symmetric
           matrix.

Function/Subroutine Documentation
   subroutine csyr (character UPLO, integer N, complex ALPHA, complex,
       dimension( * ) X, integer INCX, complex, dimension( lda, * ) A, integer
       LDA)
       CSYR performs the symmetric rank-1 update of a complex symmetric
       matrix.

Purpose:
   CSYR   performs the symmetric rank 1 operation

   A := alpha*x*x**H + A,

   where alpha is a complex scalar, x is an n element vector and A is an
   n by n symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as
```

```
  follows:

  UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.
  UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

  Unchanged on exit.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is COMPLEX
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

X
  X is COMPLEX array, dimension at least ( 1 + ( N - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the N-
  element vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

A
  A is COMPLEX array, dimension ( LDA, N )
  Before entry, with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the symmetric matrix and the strictly
  lower triangular part of A is not referenced. On exit, the
  upper triangular part of the array A is overwritten by the
  upper triangular part of the updated matrix.
  Before entry, with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the symmetric matrix and the strictly
  upper triangular part of A is not referenced. On exit, the
  lower triangular part of the array A is overwritten by the
  lower triangular part of the updated matrix.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, N ).
  Unchanged on exit.

SYNOPSIS
   Functions/Subroutines
       subroutine csyswapr (UPLO, N, A, LDA, I1, I2)
           CSYSWAPR

Function/Subroutine Documentation
   subroutine csyswapr (character UPLO, integer N, complex, dimension( lda, n
       ) A, integer LDA, integer I1, integer I2)
       CSYSWAPR

Purpose:
   CSYSWAPR applies an elementary permutation on the rows and the columns of
   a symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
```

```
  A is COMPLEX array, dimension (LDA,N)
  On entry, the NB diagonal matrix D and the multipliers
  used to obtain the factor U or L as computed by CSYTRF.

  On exit, if INFO = 0, the (symmetric) inverse of the original
  matrix.  If UPLO = 'U', the upper triangular part of the
  inverse is formed and the part of A below the diagonal is not
  referenced; if UPLO = 'L' the lower triangular part of the
  inverse is formed and the part of A above the diagonal is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

I1
  I1 is INTEGER
  Index of the first row to swap

I2
  I2 is INTEGER
  Index of the second row to swap
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine ctgsy2 (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, RDSUM, RDSCAL, INFO)
           CTGSY2 solves the generalized Sylvester equation (unblocked
           algorithm).

Function/Subroutine Documentation
   subroutine ctgsy2 (character TRANS, integer IJOB, integer M, integer N,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( ldb, *
       ) B, integer LDB, complex, dimension( ldc, * ) C, integer LDC, complex,
       dimension( ldd, * ) D, integer LDD, complex, dimension( lde, * ) E,
       integer LDE, complex, dimension( ldf, * ) F, integer LDF, real SCALE,
       real RDSUM, real RDSCAL, integer INFO)
       CTGSY2 solves the generalized Sylvester equation (unblocked algorithm).

Purpose:
   CTGSY2 solves the generalized Sylvester equation

               A * R - L * B = scale *  C               (1)
               D * R - L * E = scale * F

   using Level 1 and 2 BLAS, where R and L are unknown M-by-N matrices,
   (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M,
   N-by-N and M-by-N, respectively. A, B, D and E are upper triangular
   (i.e., (A,D) and (B,E) in generalized Schur form).
```

```
  The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output
  scaling factor chosen to avoid overflow.

  In matrix notation solving equation (1) corresponds to solve
  Zx = scale * b, where Z is defined as

             Z = [ kron(In, A)  -kron(B**H, Im) ]             (2)
                 [ kron(In, D)  -kron(E**H, Im) ],

  Ik is the identity matrix of size k and X**H is the transpose of X.
  kron(X, Y) is the Kronecker product between the matrices X and Y.

  If TRANS = 'C', y in the conjugate transposed system Z**H*y = scale*b
  is solved for, which is equivalent to solve for R and L in

                A**H * R  + D**H * L   = scale * C           (3)
                R  * B**H + L  * E**H  = scale * -F

  This case is used to compute an estimate of Dif[(A, D), (B, E)] =
  = sigma_min(Z) using reverse communicaton with CLACON.

  CTGSY2 also (IJOB >= 1) contributes to the computation in CTGSYL
  of an upper bound on the separation between to matrix pairs. Then
  the input (A, D), (B, E) are sub-pencils of two matrix pairs in CTGSYL.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N', solve the generalized Sylvester equation (1).
   = 'T': solve the 'transposed' system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   =0: solve (1) only.
   =1: A contribution from this subsystem to a Frobenius
       norm-based estimate of the separation between two matrix
       pairs is computed. (look ahead strategy is used).
   =2: A contribution from this subsystem to a Frobenius
       norm-based estimate of the separation between two matrix
       pairs is computed. (SGECON on sub-systems is used.)
   Not referenced if TRANS = 'T'.

 M
   M is INTEGER
   On entry, M specifies the order of A and D, and the row
   dimension of C, F, R and L.

 N
```

```
  N is INTEGER
  On entry, N specifies the order of B and E, and the column
  dimension of C, F, R and L.

A
  A is COMPLEX array, dimension (LDA, M)
  On entry, A contains an upper triangular matrix.

LDA
  LDA is INTEGER
  The leading dimension of the matrix A. LDA >= max(1, M).

B
  B is COMPLEX array, dimension (LDB, N)
  On entry, B contains an upper triangular matrix.

LDB
  LDB is INTEGER
  The leading dimension of the matrix B. LDB >= max(1, N).

C
  C is COMPLEX array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1).
  On exit, if IJOB = 0, C has been overwritten by the solution
  R.

LDC
  LDC is INTEGER
  The leading dimension of the matrix C. LDC >= max(1, M).

D
  D is COMPLEX array, dimension (LDD, M)
  On entry, D contains an upper triangular matrix.

LDD
  LDD is INTEGER
  The leading dimension of the matrix D. LDD >= max(1, M).

E
  E is COMPLEX array, dimension (LDE, N)
  On entry, E contains an upper triangular matrix.

LDE
  LDE is INTEGER
  The leading dimension of the matrix E. LDE >= max(1, N).

F
  F is COMPLEX array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
```

```
  equation in (1).
  On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF
  LDF is INTEGER
  The leading dimension of the matrix F. LDF >= max(1, M).

SCALE
  SCALE is REAL
  On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions
  R and L (C and F on entry) will hold the solutions to a
  slightly perturbed system but the input matrices A, B, D and
  E have not been changed. If SCALE = 0, R and L will hold the
  solutions to the homogeneous system with C = F = 0.
  Normally, SCALE = 1.

RDSUM
  RDSUM is REAL
  On entry, the sum of squares of computed contributions to
  the Dif-estimate under computation by CTGSYL, where the
  scaling factor RDSCAL (see below) has been factored out.
  On exit, the corresponding sum of squares updated with the
  contributions from the current sub-system.
  If TRANS = 'T' RDSUM is not touched.
  NOTE: RDSUM only makes sense when CTGSY2 is called by CTGSYL.

RDSCAL
  RDSCAL is REAL
  On entry, scaling factor used to prevent overflow in RDSUM.
  On exit, RDSCAL is updated w.r.t. the current contributions
  in RDSUM.
  If TRANS = 'T', RDSCAL is not touched.
  NOTE: RDSCAL only makes sense when CTGSY2 is called by CTGSYL.

INFO
  INFO is INTEGER
  On exit, if INFO is set to
    =0: Successful exit
    <0: If INFO = -i, input argument number i is illegal.
    >0: The matrix pairs (A, D) and (B, E) have common or very
         close eigenvalues.

SYNOPSIS
   Functions/Subroutines
       subroutine zlaesy (A, B, C, RT1, RT2, EVSCAL, CS1, SN1)
           ZLAESY computes the eigenvalues and eigenvectors of a 2-by-2
           complex symmetric matrix.

Function/Subroutine Documentation
   subroutine zlaesy (complex*16 A, complex*16 B, complex*16 C, complex*16
       RT1, complex*16 RT2, complex*16 EVSCAL, complex*16 CS1, complex*16 SN1)
       ZLAESY computes the eigenvalues and eigenvectors of a 2-by-2 complex
       symmetric matrix.

Purpose:
   ZLAESY computes the eigendecomposition of a 2-by-2 symmetric matrix
      ( ( A, B );( B, C ) )
   provided the norm of the matrix of eigenvectors is larger than
   some threshold value.

   RT1 is the eigenvalue of larger absolute value, and RT2 of
   smaller absolute value.  If the eigenvectors are computed, then
   on return ( CS1, SN1 ) is the unit eigenvector for RT1, hence

   [  CS1     SN1   ] . [ A  B ] . [ CS1    -SN1   ] = [ RT1  0  ]
   [ -SN1     CS1   ]   [ B  C ]   [ SN1     CS1   ]   [  0  RT2 ]

Parameters:

 A
   A is COMPLEX*16
   The ( 1, 1 ) element of input matrix.

 B
   B is COMPLEX*16
   The ( 1, 2 ) element of input matrix.  The ( 2, 1 ) element
   is also given by B, since the 2-by-2 matrix is symmetric.

 C
   C is COMPLEX*16
   The ( 2, 2 ) element of input matrix.

 RT1
   RT1 is COMPLEX*16
   The eigenvalue of larger modulus.

 RT2
```

```
  RT2 is COMPLEX*16
  The eigenvalue of smaller modulus.

EVSCAL
  EVSCAL is COMPLEX*16
  The complex value by which the eigenvector matrix was scaled
  to make it orthonormal.  If EVSCAL is zero, the eigenvectors
  were not computed.  This means one of two things:  the 2-by-2
  matrix could not be diagonalized, or the norm of the matrix
  of eigenvectors before scaling was larger than the threshold
  value THRESH (set below).

CS1
  CS1 is COMPLEX*16

SN1
  SN1 is COMPLEX*16
  If EVSCAL .NE. 0,  ( CS1, SN1 ) is the unit right eigenvector for RT1.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       double precision function zlansy (NORM, UPLO, N, A, LDA, WORK)
           ZLANSY returns the value of the 1-norm, or the Frobenius norm, or
           the infinity norm, or the element of largest absolute value of a
           complex symmetric matrix.

Function/Subroutine Documentation
   double precision function zlansy (character NORM, character UPLO, integer
       N, complex*16, dimension( lda, * ) A, integer LDA, double precision,
       dimension( * ) WORK)
       ZLANSY returns the value of the 1-norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a complex
       symmetric matrix.

Purpose:
   ZLANSY  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   complex symmetric matrix A.

 Returns:

   ZLANSY

       ZLANSY = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in ZLANSY as described above.
```

```
UPLO
  UPLO is CHARACTER*1
  Specifies whether the upper or lower triangular part of the
  symmetric matrix A is to be referenced.
  = 'U':  Upper triangular part of A is referenced
  = 'L':  Lower triangular part of A is referenced

N
  N is INTEGER
  The order of the matrix A.  N >= 0.  When N = 0, ZLANSY is set to zero.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading n by n
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading n by n lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(N,1).

WORK
  WORK is DOUBLE PRECISION array, dimension (MAX(1,LWORK)),
  where LWORK >= N when NORM = 'I' or '1' or 'O'; otherwise,
  WORK is not referenced.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zlaqsy (UPLO, N, A, LDA, S, SCOND, AMAX, EQUED)
           ZLAQSY scales a symmetric/Hermitian matrix, using scaling factors
           computed by spoequ.

Function/Subroutine Documentation
   subroutine zlaqsy (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, double precision, dimension( * ) S, double precision
       SCOND, double precision AMAX, character EQUED)
       ZLAQSY scales a symmetric/Hermitian matrix, using scaling factors
       computed by spoequ.

Purpose:
   ZLAQSY equilibrates a symmetric matrix A using the scaling factors
   in the vector S.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n by n lower triangular part of A contains the lower
```

```
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if EQUED = 'Y', the equilibrated matrix:
  diag(S) * A * diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(N,1).

S
  S is DOUBLE PRECISION array, dimension (N)
  The scale factors for A.

SCOND
  SCOND is DOUBLE PRECISION
  Ratio of the smallest S(i) to the largest S(i).

AMAX
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix entry.

EQUED
  EQUED is CHARACTER*1
  Specifies whether or not equilibration was done.
  = 'N':  No equilibration.
  = 'Y':  Equilibration was done, i.e., A has been replaced by
          diag(S) * A * diag(S).

Internal Parameters:

  THRESH is a threshold value used to decide if scaling should be done
  based on the ratio of the scaling factors.  If SCOND < THRESH,
  scaling is done.

  LARGE and SMALL are threshold values used to decide if scaling should
  be done based on the absolute size of the largest matrix element.
  If AMAX > LARGE or AMAX < SMALL, scaling is done.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsymv (UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
           ZSYMV computes a matrix-vector product for a complex symmetric
           matrix.

Function/Subroutine Documentation
   subroutine zsymv (character UPLO, integer N, complex*16 ALPHA, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( * ) X,
       integer INCX, complex*16 BETA, complex*16, dimension( * ) Y, integer
       INCY)
       ZSYMV computes a matrix-vector product for a complex symmetric matrix.

Purpose:
   ZSYMV  performs the matrix-vector  operation

   y := alpha*A*x + beta*y,

   where alpha and beta are scalars, x and y are n element vectors and
   A is an n by n symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the upper or lower
   triangular part of the array A is to be referenced as
   follows:

   UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.
```

```
  UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

  Unchanged on exit.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is COMPLEX*16
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

A
  A is COMPLEX*16 array, dimension ( LDA, N )
  Before entry, with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the symmetric matrix and the strictly
  lower triangular part of A is not referenced.
  Before entry, with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the symmetric matrix and the strictly
  upper triangular part of A is not referenced.
  Unchanged on exit.

LDA
  LDA is INTEGER
  On entry, LDA specifies the first dimension of A as declared
  in the calling (sub) program. LDA must be at least max( 1, N ).
  Unchanged on exit.

X
  X is COMPLEX*16 array, dimension at least
  ( 1 + ( N - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the N-element vector x.
                     Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

BETA
  BETA is COMPLEX*16
  On entry, BETA specifies the scalar beta. When BETA is
  supplied as zero then Y need not be set on input.
  Unchanged on exit.
```

```
 Y
   Y is COMPLEX*16 array, dimension at least
   ( 1 + ( N - 1 )*abs( INCY ) ).
   Before entry, the incremented array Y must contain the n
   element vector y. On exit, Y is overwritten by the updated vector y.

 INCY
   INCY is INTEGER
   On entry, INCY specifies the increment for the elements of
   Y. INCY must not be zero.
   Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsyr (UPLO, N, ALPHA, X, INCX, A, LDA)
           ZSYR performs the symmetric rank-1 update of a complex symmetric
           matrix.

Function/Subroutine Documentation
   subroutine zsyr (character UPLO, integer N, complex*16 ALPHA, complex*16,
       dimension( * ) X, integer INCX, complex*16, dimension( lda, * ) A,
       integer LDA)
       ZSYR performs the symmetric rank-1 update of a complex symmetric
       matrix.

Purpose:
   ZSYR   performs the symmetric rank 1 operation

   A := alpha*x*x**H + A,

   where alpha is a complex scalar, x is an n element vector and A is an
   n by n symmetric matrix.

Parameters:

 UPLO
```

```
  UPLO is CHARACTER*1
  On entry, UPLO specifies whether the upper or lower
  triangular part of the array A is to be referenced as
  follows:

  UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.
  UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

  Unchanged on exit.

N
  N is INTEGER
  On entry, N specifies the order of the matrix A.
  N must be at least zero.
  Unchanged on exit.

ALPHA
  ALPHA is COMPLEX*16
  On entry, ALPHA specifies the scalar alpha.
  Unchanged on exit.

X
  X is COMPLEX*16 array, dimension at least
  ( 1 + ( N - 1 )*abs( INCX ) ).
  Before entry, the incremented array X must contain the N-element vector x.
  Unchanged on exit.

INCX
  INCX is INTEGER
  On entry, INCX specifies the increment for the elements of
  X. INCX must not be zero.
  Unchanged on exit.

A
  A is COMPLEX*16 array, dimension ( LDA, N )
  Before entry, with  UPLO = 'U' or 'u', the leading n by n
  upper triangular part of the array A must contain the upper
  triangular part of the symmetric matrix and the strictly
  lower triangular part of A is not referenced. On exit, the
  upper triangular part of the array A is overwritten by the
  upper triangular part of the updated matrix.
  Before entry, with UPLO = 'L' or 'l', the leading n by n
  lower triangular part of the array A must contain the lower
  triangular part of the symmetric matrix and the strictly
  upper triangular part of A is not referenced. On exit, the
  lower triangular part of the array A is overwritten by the
  lower triangular part of the updated matrix.

LDA
  LDA is INTEGER
```

```
On entry, LDA specifies the first dimension of A as declared
in the calling (sub) program. LDA must be at least max( 1, N ).
Unchanged on exit.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zsyswapr (UPLO, N, A, LDA, I1, I2)
           ZSYSWAPR

Function/Subroutine Documentation
   subroutine zsyswapr (character UPLO, integer N, complex*16, dimension( lda,
       n ) A, integer LDA, integer I1, integer I2)
       ZSYSWAPR

Purpose:
   ZSYSWAPR applies an elementary permutation on the rows and the columns of
   a symmetric matrix.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the details of the factorization are stored
   as an upper or lower triangular matrix.
   = 'U':  Upper triangular, form is A = U*D*U**T;
   = 'L':  Lower triangular, form is A = L*D*L**T.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the NB diagonal matrix D and the multipliers
   used to obtain the factor U or L as computed by ZSYTRF.

   On exit, if INFO = 0, the (symmetric) inverse of the original
   matrix.  If UPLO = 'U', the upper triangular part of the
```

```
  inverse is formed and the part of A below the diagonal is not
  referenced; if UPLO = 'L' the lower triangular part of the
  inverse is formed and the part of A above the diagonal is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

I1
  I1 is INTEGER
  Index of the first row to swap

I2
  I2 is INTEGER
  Index of the second row to swap
```

SYNOPSIS
   Functions/Subroutines
       subroutine ztgsy2 (TRANS, IJOB, M, N, A, LDA, B, LDB, C, LDC, D, LDD,
           E, LDE, F, LDF, SCALE, RDSUM, RDSCAL, INFO)
           ZTGSY2 solves the generalized Sylvester equation (unblocked
           algorithm).

Function/Subroutine Documentation
   subroutine ztgsy2 (character TRANS, integer IJOB, integer M, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldb, * ) B, integer LDB, complex*16, dimension( ldc, * ) C, integer
       LDC, complex*16, dimension( ldd, * ) D, integer LDD, complex*16,
       dimension( lde, * ) E, integer LDE, complex*16, dimension( ldf, * ) F,
       integer LDF, double precision SCALE, double precision RDSUM, double
       precision RDSCAL, integer INFO)
       ZTGSY2 solves the generalized Sylvester equation (unblocked algorithm).

Purpose:
   ZTGSY2 solves the generalized Sylvester equation

   A * R - L * B = scale * C               (1)
   D * R - L * E = scale * F

   using Level 1 and 2 BLAS, where R and L are unknown M-by-N matrices,
   (A, D), (B, E) and (C, F) are given matrix pairs of size M-by-M,
   N-by-N and M-by-N, respectively. A, B, D and E are upper triangular
   (i.e., (A,D) and (B,E) in generalized Schur form).

   The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output
   scaling factor chosen to avoid overflow.

   In matrix notation solving equation (1) corresponds to solve
   Zx = scale * b, where Z is defined as
```

```
  Z = [ kron(In, A)  -kron(B**H, Im) ]             (2)
      [ kron(In, D)  -kron(E**H, Im) ],

  Ik is the identity matrix of size k and X**H is the conjuguate
  transpose of X.  kron(X, Y) is the Kronecker product
  between the matrices X and Y.

  If TRANS = 'C', y in the conjugate transposed system Z**H*y = scale*b
  is solved for, which is equivalent to solve for R and L in

  A**H * R  + D**H * L   = scale * C           (3)
  R  * B**H + L  * E**H  = scale * -F

  This case is used to compute an estimate of Dif[(A, D), (B, E)] =
  = sigma_min(Z) using reverse communicaton with ZLACON.

  ZTGSY2 also (IJOB >= 1) contributes to the computation in ZTGSYL
  of an upper bound on the separation between to matrix pairs. Then
  the input (A, D), (B, E) are sub-pencils of two matrix pairs in ZTGSYL.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   = 'N', solve the generalized Sylvester equation (1).
   = 'T': solve the 'transposed' system (3).

 IJOB
   IJOB is INTEGER
   Specifies what kind of functionality to be performed.
   =0: solve (1) only.
   =1: A contribution from this subsystem to a Frobenius
       norm-based estimate of the separation between two matrix
       pairs is computed. (look ahead strategy is used).
   =2: A contribution from this subsystem to a Frobenius
       norm-based estimate of the separation between two matrix
       pairs is computed. (DGECON on sub-systems is used.)
   Not referenced if TRANS = 'T'.

 M
   M is INTEGER
   On entry, M specifies the order of A and D, and the row
   dimension of C, F, R and L.

 N
   N is INTEGER
   On entry, N specifies the order of B and E, and the column
   dimension of C, F, R and L.

 A
```

```
  A is COMPLEX*16 array, dimension (LDA, M)
  On entry, A contains an upper triangular matrix.

LDA
  LDA is INTEGER
  The leading dimension of the matrix A. LDA >= max(1, M).

B
  B is COMPLEX*16 array, dimension (LDB, N)
  On entry, B contains an upper triangular matrix.

LDB
  LDB is INTEGER
  The leading dimension of the matrix B. LDB >= max(1, N).

C
  C is COMPLEX*16 array, dimension (LDC, N)
  On entry, C contains the right-hand-side of the first matrix
  equation in (1).
  On exit, if IJOB = 0, C has been overwritten by the solution R.

LDC
  LDC is INTEGER
  The leading dimension of the matrix C. LDC >= max(1, M).

D
  D is COMPLEX*16 array, dimension (LDD, M)
  On entry, D contains an upper triangular matrix.

LDD
  LDD is INTEGER
  The leading dimension of the matrix D. LDD >= max(1, M).

E
  E is COMPLEX*16 array, dimension (LDE, N)
  On entry, E contains an upper triangular matrix.

LDE
  LDE is INTEGER
  The leading dimension of the matrix E. LDE >= max(1, N).

F
  F is COMPLEX*16 array, dimension (LDF, N)
  On entry, F contains the right-hand-side of the second matrix
  equation in (1).
  On exit, if IJOB = 0, F has been overwritten by the solution L.

LDF
  LDF is INTEGER
  The leading dimension of the matrix F. LDF >= max(1, M).
```

```
 SCALE
   SCALE is DOUBLE PRECISION
   On exit, 0 <= SCALE <= 1. If 0 < SCALE < 1, the solutions
   R and L (C and F on entry) will hold the solutions to a
   slightly perturbed system but the input matrices A, B, D and
   E have not been changed. If SCALE = 0, R and L will hold the
   solutions to the homogeneous system with C = F = 0.
   Normally, SCALE = 1.

 RDSUM
   RDSUM is DOUBLE PRECISION
   On entry, the sum of squares of computed contributions to
   the Dif-estimate under computation by ZTGSYL, where the
   scaling factor RDSCAL (see below) has been factored out.
   On exit, the corresponding sum of squares updated with the
   contributions from the current sub-system.
   If TRANS = 'T' RDSUM is not touched.
   NOTE: RDSUM only makes sense when ZTGSY2 is called by ZTGSYL.

 RDSCAL
   RDSCAL is DOUBLE PRECISION
   On entry, scaling factor used to prevent overflow in RDSUM.
   On exit, RDSCAL is updated w.r.t. the current contributions
   in RDSUM.
   If TRANS = 'T', RDSCAL is not touched.
   NOTE: RDSCAL only makes sense when ZTGSY2 is called by ZTGSYL.

 INFO
   INFO is INTEGER
   On exit, if INFO is set to
   =0: Successful exit
   <0: If INFO = -i, input argument number i is illegal.
   >0: The matrix pairs (A, D) and (B, E) have common or very
       close eigenvalues.

SYNOPSIS
   Functions/Subroutines
       subroutine dposv (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
            DPOSV computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine dposv (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, integer INFO)
        DPOSV computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   DPOSV computes the solution to a real system of linear equations
      A * X = B,
   where A is an N-by-N symmetric positive definite matrix and X and B
   are N-by-NRHS matrices.

   The Cholesky decomposition is used to factor A as
      A = U**T* U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower triangular
   matrix.  The factored form of A is then used to solve the system of
   equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the
   matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
```

```
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i of A is not
        positive definite, so the factorization could not be
        completed, and the solution has not been computed.
```

       DPOSVX computes the solution to system of linear equations A * X = B
      for PO matrices

Purpose:
   DPOSVX uses the Cholesky factorization A = U**T*U or A = L*L**T to
   compute the solution to a real system of linear equations
      A * X = B,
   where A is an N-by-N symmetric positive definite matrix and X and B
   are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
         diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**T* U,  if UPLO = 'U', or
         A = L * L**T,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix A.
      If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
```

```
  Specifies whether or not the factored form of the matrix A is
  supplied on entry, and if not, whether the matrix A should be
  equilibrated before it is factored.
  = 'F':  On entry, AF contains the factored form of A.
          If EQUED = 'Y', the matrix A has been equilibrated
          with scaling factors given by S.  A and AF will not be modified.
  = 'N':  The matrix A will be copied to AF and factored.
  = 'E':  The matrix A will be equilibrated if necessary, then
          copied to AF and factored.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the
  matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A, except if FACT = 'F' and
  EQUED = 'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.  A is not modified if
  FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T, in the same storage
```

```
  format as A.  If EQUED .ne. 'N', then AF is the factored form
  of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Equilibration was done, i.e., A has been replaced by
          diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is DOUBLE PRECISION array, dimension (N)
  The scale factors for A; not accessed if EQUED = 'N'.  S is
  an input argument if FACT = 'F'; otherwise, S is an output
  argument.  If FACT = 'F' and EQUED = 'Y', each element of S
  must be positive.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y',
  B is overwritten by diag(S) * B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to
  the original system of equations.  Note that if EQUED = 'Y',
  A and B are modified on exit, and the solution to the
  equilibrated system is inv(diag(S))*X.
```

```
LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
  <= N:  the leading minor of order i of A is
       not positive definite, so the factorization
       could not be completed, and the solution has not
       been computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
       precision, meaning that the matrix is singular
       to working precision.  Nevertheless, the
       solution and error bounds are computed because
       there are a number of situations where the
```

```
        computed solution can be more accurate than the
        value of RCOND would suggest.
```

       IWORK, integer INFO)
        DPOSVXX computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   DPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a double precision system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. DPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   DPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   DPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what DPOSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:

      diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
```

```
         A = U**T* U,  if UPLO = 'U', or
         A = L * L**T,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A (see argument RCOND).  If the reciprocal of the condition number
      is less than machine precision, the routine still goes on to solve
      for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF contains the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by S.
      A and AF are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
```

```
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  On entry, the symmetric matrix A, except if FACT = 'F' and EQUED =
  'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading N-by-N upper
  triangular part of A contains the upper triangular part of the
  matrix A, and the strictly lower triangular part of A is not
  referenced.  If UPLO = 'L', the leading N-by-N lower triangular
  part of A contains the lower triangular part of the matrix A, and
  the strictly upper triangular part of A is not referenced.  A is
  not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED =
  'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored
  form of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).
```

```
EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Both row and column equilibration, i.e., A has been
          replaced by diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit if
  EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
```

```
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
          max_j (abs(XTRUE(j,i) - X(j,i)))
           ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
```

```
      reciprocal condition number is less than the threshold
      sqrt(n) * dlamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
      sqrt(n) * dlamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated normwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * dlamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*A, where S scales each row by a power of the
      radix so all absolute row sums of Z are approximately 1.

 ERR_BNDS_COMP
   ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
   For each right-hand side, this array contains information about
   various error bounds and condition numbers corresponding to the
   componentwise relative error, which is defined as follows:

   Componentwise relative error in the ith solution vector:
                   abs(XTRUE(j,i) - X(j,i))
             max_j ----------------------
                         abs(X(j,i))

   The array is indexed by the right-hand side i (on which the
   componentwise relative error depends), and the type of error
   information as described below. There currently are up to three
   pieces of information returned for each right-hand side. If
   componentwise accuracy is not requested (PARAMS(3) = 0.0), then
   ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
   the first (:,N_ERR_BNDS) entries are returned.

   The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
   right-hand side.

   The second index in ERR_BNDS_COMP(:,err) contains the following
   three fields:

   err = 1 "Trust/don't trust" boolean. Trust the answer if the
      reciprocal condition number is less than the threshold
      sqrt(n) * dlamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
```

```
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)
```

```
 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  Successful exit. The solution to every right-hand side is
         guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
       has been completed, but the factor U is exactly singular, so
       the solution and error bounds could not be computed. RCOND = 0
       is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
       not guaranteed. The solutions corresponding to other right-
       hand sides K with K > J may not be guaranteed as well, but
       only the first such right-hand side is reported. If a small
       componentwise error is not requested (PARAMS(3) = 0.0) then
       the Jth right-hand side is the first with a normwise error
       bound that is not guaranteed (the smallest J such
       that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
       the Jth right-hand side is the first with either a normwise or
       componentwise error bound that is not guaranteed (the smallest
       J such that either ERR_BNDS_NORM(J,1) = 0.0 or
       ERR_BNDS_COMP(J,1) = 0.0). See the definition of
       ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
       about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine dsposv (UPLO, N, NRHS, A, LDA, B, LDB, X, LDX, WORK, SWORK,
           ITER, INFO)
            DSPOSV computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine dsposv (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, double precision, dimension( ldx, *
       ) X, integer LDX, double precision, dimension( n, * ) WORK, real,
       dimension( * ) SWORK, integer ITER, integer INFO)
        DSPOSV computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   DSPOSV computes the solution to a real system of linear equations
   A * X = B,
   where A is an N-by-N symmetric positive definite matrix and X and B
   are N-by-NRHS matrices.

   DSPOSV first attempts to factorize the matrix in SINGLE PRECISION
   and use this factorization within an iterative refinement procedure
   to produce a solution with DOUBLE PRECISION normwise backward error
   quality (see below). If the approach fails the method switches to a
   DOUBLE PRECISION factorization and solve.

   The iterative refinement is not going to be a winning strategy if
   the ratio SINGLE PRECISION performance over DOUBLE PRECISION
   performance is too small. A reasonable strategy should take the
   number of right-hand sides and the size of the matrix into account.
   This might be done with a call to ILAENV in the future. Up to now, we
   always try iterative refinement.

   The iterative refinement process is stopped if
      ITER > ITERMAX
   or for all the RHS we have:
      RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
   where
      o ITER is the number of the current iteration in the iterative
        refinement process
      o RNRM is the infinity-norm of the residual
```

```
      o XNRM is the infinity-norm of the solution
      o ANRM is the infinity-operator-norm of the matrix A
      o EPS is the machine epsilon returned by DLAMCH('Epsilon')
   The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array,
   dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
   On exit, if iterative refinement has been successfully used
   (INFO.EQ.0 and ITER.GE.0, see description below), then A is
   unchanged, if double precision factorization has been used
   (INFO.EQ.0 and ITER.LT.0, see description below), then the
   array A contains the factor U or L from the Cholesky
   factorization A = U**T*U or A = L*L**T.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   The N-by-NRHS right hand side matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).
```

```
X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (N,NRHS)
  This array is used to hold the residual vectors.

SWORK
  SWORK is REAL array, dimension (N*(N+NRHS))
  This array is used to use the single precision matrix and the
  right-hand sides or solutions in single precision.

ITER
  ITER is INTEGER
  < 0: iterative refinement has failed, double precision
  factorization has been performed
  -1 : the routine fell back to full precision for
       implementation- or machine-specific reasons
  -2 : narrowing the precision induced an overflow,
       the routine fell back to full precision
  -3 : failure of SPOTRF
  -31: stop the iterative refinement after the 30th iterations
  > 0: iterative refinement has been sucessfully used.
       Returns the number of iterations

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i of (DOUBLE
        PRECISION) A is not positive definite, so the
        factorization could not be completed, and the solution
        has not been computed.

SYNOPSIS
   Functions/Subroutines
       subroutine sposv (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
            SPOSV computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine sposv (character UPLO, integer N, integer NRHS, real, dimension(
       lda, * ) A, integer LDA, real, dimension( ldb, * ) B, integer LDB,
       integer INFO)
        SPOSV computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   SPOSV computes the solution to a real system of linear equations
      A * X = B,
   where A is an N-by-N symmetric positive definite matrix and X and B
   are N-by-NRHS matrices.

   The Cholesky decomposition is used to factor A as
      A = U**T* U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower triangular
   matrix.  The factored form of A is then used to solve the system of
   equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
```

```
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i of A is not
        positive definite, so the factorization could not be
        completed, and the solution has not been computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sposvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B,
           LDB, X, LDX, RCOND, FERR, BERR, WORK, IWORK, INFO)
            SPOSVX computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine sposvx (character FACT, character UPLO, integer N, integer NRHS,
       real, dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * )
       AF, integer LDAF, character EQUED, real, dimension( * ) S, real,
       dimension( ldb, * ) B, integer LDB, real, dimension( ldx, * ) X,
       integer LDX, real RCOND, real, dimension( * ) FERR, real, dimension( *
       ) BERR, real, dimension( * ) WORK, integer, dimension( * ) IWORK,
       integer INFO)
        SPOSVX computes the solution to system of linear equations A * X = B
```

```
       for PO matrices

Purpose:
   SPOSVX uses the Cholesky factorization A = U**T*U or A = L*L**T to
   compute the solution to a real system of linear equations
      A * X = B,
   where A is an N-by-N symmetric positive definite matrix and X and B
   are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
         diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**T* U,  if UPLO = 'U', or
         A = L * L**T,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
```

```
  supplied on entry, and if not, whether the matrix A should be
  equilibrated before it is factored.
  = 'F':  On entry, AF contains the factored form of A.
     If EQUED = 'Y', the matrix A has been equilibrated
     with scaling factors given by S.  A and AF will not
     be modified.
  = 'N':  The matrix A will be copied to AF and factored.
  = 'E':  The matrix A will be equilibrated if necessary, then
     copied to AF and factored.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A, except if FACT = 'F' and
  EQUED = 'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.  A is not modified if
  FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is REAL array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored form
```

```
  of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Equilibration was done, i.e., A has been replaced by
     diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is REAL array, dimension (N)
  The scale factors for A; not accessed if EQUED = 'N'.  S is
  an input argument if FACT = 'F'; otherwise, S is an output
  argument.  If FACT = 'F' and EQUED = 'Y', each element of S
  must be positive.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y',
  B is overwritten by diag(S) * B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to
  the original system of equations.  Note that if EQUED = 'Y',
  A and B are modified on exit, and the solution to the
  equilibrated system is inv(diag(S))*X.
```

```
LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
    <= N:  the leading minor of order i of A is
       not positive definite, so the factorization
       could not be completed, and the solution has not
       been computed. RCOND = 0 is returned.
    = N+1: U is nonsingular, but RCOND is less than machine
       precision, meaning that the matrix is singular
       to working precision.  Nevertheless, the
       solution and error bounds are computed because
       there are a number of situations where the
       computed solution can be more accurate than the
```

```
        value of RCOND would suggest.
```

     ) PARAMS, real, dimension( * ) WORK, integer, dimension( * ) IWORK,
     integer INFO)
      SPOSVXX computes the solution to system of linear equations A * X = B
     for PO matrices

Purpose:
   SPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. SPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   SPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   SPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what SPOSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

      diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**T* U,  if UPLO = 'U', or
         A = L * L**T,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
```

```
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A (see argument RCOND).  If the reciprocal of the condition number
      is less than machine precision, the routine still goes on to solve
      for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF contains the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by S.
      A and AF are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
```

```
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A, except if FACT = 'F' and EQUED =
  'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading N-by-N upper
  triangular part of A contains the upper triangular part of the
  matrix A, and the strictly lower triangular part of A is not
  referenced.  If UPLO = 'L', the leading N-by-N lower triangular
  part of A contains the lower triangular part of the matrix A, and
  the strictly upper triangular part of A is not referenced.  A is
  not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED =
  'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is REAL array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored
  form of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
```

```
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Both row and column equilibration, i.e., A has been
          replaced by diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit if
  EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.
```

```
RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').
```

```
  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.
```

```
  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)
```

```
 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  Successful exit. The solution to every right-hand side is
         guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine cposv (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
            CPOSV computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine cposv (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldb, * ) B,
       integer LDB, integer INFO)
        CPOSV computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   CPOSV computes the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N Hermitian positive definite matrix and X and B
   are N-by-NRHS matrices.

   The Cholesky decomposition is used to factor A as
      A = U**H* U,  if UPLO = 'U', or
      A = L * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and  L is a lower triangular
   matrix.  The factored form of A is then used to solve the system of
   equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the Hermitian matrix A.  If UPLO = 'U', the leading
```

```
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**H*U or A = L*L**H.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i of A is not
        positive definite, so the factorization could not be
        completed, and the solution has not been computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cposvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B,
           LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
            CPOSVX computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine cposvx (character FACT, character UPLO, integer N, integer NRHS,
       complex, dimension( lda, * ) A, integer LDA, complex, dimension( ldaf,
       * ) AF, integer LDAF, character EQUED, real, dimension( * ) S, complex,
       dimension( ldb, * ) B, integer LDB, complex, dimension( ldx, * ) X,
       integer LDX, real RCOND, real, dimension( * ) FERR, real, dimension( *
       ) BERR, complex, dimension( * ) WORK, real, dimension( * ) RWORK,
       integer INFO)
        CPOSVX computes the solution to system of linear equations A * X = B
```

```
       for PO matrices

Purpose:
   CPOSVX uses the Cholesky factorization A = U**H*U or A = L*L**H to
   compute the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N Hermitian positive definite matrix and X and B
   are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
         diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**H* U,  if UPLO = 'U', or
         A = L * L**H,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before
      equilibration.

Parameters:

 FACT
```

```
  FACT is CHARACTER*1
  Specifies whether or not the factored form of the matrix A is
  supplied on entry, and if not, whether the matrix A should be
  equilibrated before it is factored.
  = 'F':  On entry, AF contains the factored form of A.
     If EQUED = 'Y', the matrix A has been equilibrated
     with scaling factors given by S.  A and AF will not
     be modified.
  = 'N':  The matrix A will be copied to AF and factored.
  = 'E':  The matrix A will be equilibrated if necessary, then
     copied to AF and factored.

UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the Hermitian matrix A, except if FACT = 'F' and
  EQUED = 'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.  A is not modified if
  FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
```

```
  factorization A = U**H*U or A = L*L**H, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored form
  of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**H*U or A = L*L**H of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**H*U or A = L*L**H of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Equilibration was done, i.e., A has been replaced by
          diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is REAL array, dimension (N)
  The scale factors for A; not accessed if EQUED = 'N'.  S is
  an input argument if FACT = 'F'; otherwise, S is an output
  argument.  If FACT = 'F' and EQUED = 'Y', each element of S
  must be positive.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS righthand side matrix B.
  On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y',
  B is overwritten by diag(S) * B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to
  the original system of equations.  Note that if EQUED = 'Y',
  A and B are modified on exit, and the solution to the
```

```
  equilibrated system is inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
  indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
  <= N:  the leading minor of order i of A is
     not positive definite, so the factorization
     could not be completed, and the solution has not
     been computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
```

```
      there are a number of situations where the
      computed solution can be more accurate than the
      value of RCOND would suggest.
```

       integer INFO)
        CPOSVXX computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   CPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. CPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   CPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   CPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what CPOSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:

         diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
```

```
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**T* U,  if UPLO = 'U', or
         A = L * L**T,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A (see argument RCOND).  If the reciprocal of the condition number
      is less than machine precision, the routine still goes on to solve
      for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF contains the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by S.
      A and AF are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
```

```
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the symmetric matrix A, except if FACT = 'F' and EQUED =
  'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading N-by-N upper
  triangular part of A contains the upper triangular part of the
  matrix A, and the strictly lower triangular part of A is not
  referenced.  If UPLO = 'L', the leading N-by-N lower triangular
  part of A contains the lower triangular part of the matrix A, and
  the strictly upper triangular part of A is not referenced.  A is
  not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED =
  'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored
  form of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).
```

```
EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Both row and column equilibration, i.e., A has been
          replaced by diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit if
  EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
```

```
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is REAL
  Reciprocal pivot growth.  On exit, this contains the reciprocal
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
         max_j (abs(XTRUE(j,i) - X(j,i)))
          ------------------------------
                max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:
```

```
  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
```

```
      so long as the next entry is greater than the threshold
      sqrt(n) * slamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * slamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*(A*diag(x)), where x is the solution for the
      current right-hand side and S scales each row of
      A*diag(x) by a power of the radix so all absolute row
      sums of Z are approximately 1.

 NPARAMS
   NPARAMS is INTEGER
   Specifies the number of parameters set in PARAMS.  If .LE. 0, the
   PARAMS array is never referenced and default values are used.

 PARAMS
   PARAMS is REAL array, dimension NPARAMS
   Specifies algorithm parameters.  If an entry is .LT. 0.0, then
   that entry will be filled with default value used for that
   parameter.  Only positions up to NPARAMS are accessed; defaults
   are used for higher-numbered parameters.

   PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
   refinement or not.
   Default: 1.0
   = 0.0 : No refinement is performed, and no error bounds are computed.
   = 1.0 : Use the double-precision refinement algorithm,
           possibly with doubled-single computations if the
           compilation environment does not support DOUBLE PRECISION.
   (other values are reserved for future use)

   PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
   computations allowed for refinement.
   Default: 10
   Aggressive: Set to 100 to permit convergence using approximate
               factorizations or factorizations other than LU. If
               the factorization uses a technique other than
               Gaussian elimination, the guarantees in
               err_bnds_norm and err_bnds_comp may no longer be trustworthy.

   PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
   will attempt to find a solution with small componentwise
   relative error in the double-precision algorithm.  Positive
   is true, 0.0 is false.
   Default: 1.0 (attempt componentwise convergence)
```

```
 WORK
   WORK is COMPLEX array, dimension (2*N)

 RWORK
   RWORK is REAL array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  Successful exit. The solution to every right-hand side is
   guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       subroutine zcposv (UPLO, N, NRHS, A, LDA, B, LDB, X, LDX, WORK, SWORK,
           RWORK, ITER, INFO)
            ZCPOSV computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine zcposv (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, complex*16, dimension( ldx, * ) X, integer LDX,
       complex*16, dimension( n, * ) WORK, complex, dimension( * ) SWORK,
       double precision, dimension( * ) RWORK, integer ITER, integer INFO)
        ZCPOSV computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   ZCPOSV computes the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N Hermitian positive definite matrix and X and B
   are N-by-NRHS matrices.

   ZCPOSV first attempts to factorize the matrix in COMPLEX and use this
   factorization within an iterative refinement procedure to produce a
   solution with COMPLEX*16 normwise backward error quality (see below).
   If the approach fails the method switches to a COMPLEX*16
   factorization and solve.

   The iterative refinement is not going to be a winning strategy if
   the ratio COMPLEX performance over COMPLEX*16 performance is too
   small. A reasonable strategy should take the number of right-hand
   sides and the size of the matrix into account. This might be done
   with a call to ILAENV in the future. Up to now, we always try
   iterative refinement.

   The iterative refinement process is stopped if
      ITER > ITERMAX
   or for all the RHS we have:
      RNRM < SQRT(N)*XNRM*ANRM*EPS*BWDMAX
   where
      o ITER is the number of the current iteration in the iterative
        refinement process
      o RNRM is the infinity-norm of the residual
```

```
      o XNRM is the infinity-norm of the solution
      o ANRM is the infinity-operator-norm of the matrix A
      o EPS is the machine epsilon returned by DLAMCH('Epsilon')
  The value ITERMAX and BWDMAX are fixed to 30 and 1.0D+00 respectively.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array,
   dimension (LDA,N)
   On entry, the Hermitian matrix A. If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   Note that the imaginary parts of the diagonal
   elements need not be set and are assumed to be zero.

   On exit, if iterative refinement has been successfully used
   (INFO.EQ.0 and ITER.GE.0, see description below), then A is
   unchanged, if double precision factorization has been used
   (INFO.EQ.0 and ITER.LT.0, see description below), then the
   array A contains the factor U or L from the Cholesky
   factorization A = U**H*U or A = L*L**H.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   The N-by-NRHS right hand side matrix B.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

WORK
  WORK is COMPLEX*16 array, dimension (N*NRHS)
  This array is used to hold the residual vectors.

SWORK
  SWORK is COMPLEX array, dimension (N*(N+NRHS))
  This array is used to use the single precision matrix and the
  right-hand sides or solutions in single precision.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

ITER
  ITER is INTEGER
  < 0: iterative refinement has failed, COMPLEX*16
       factorization has been performed
  -1 : the routine fell back to full precision for
       implementation- or machine-specific reasons
  -2 : narrowing the precision induced an overflow,
       the routine fell back to full precision
  -3 : failure of CPOTRF
  -31: stop the iterative refinement after the 30th iterations
  > 0: iterative refinement has been sucessfully used.
       Returns the number of iterations

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i of
     (COMPLEX*16) A is not positive definite, so the
     factorization could not be completed, and the solution
     has not been computed.
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine zposv (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
           ZPOSV computes the solution to system of linear equations A * X =
          B for PO matrices

Function/Subroutine Documentation
   subroutine zposv (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, integer INFO)
        ZPOSV computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   ZPOSV computes the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N Hermitian positive definite matrix and X and B
   are N-by-NRHS matrices.

   The Cholesky decomposition is used to factor A as
      A = U**H* U,  if UPLO = 'U', or
      A = L * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and  L is a lower triangular
   matrix.  The factored form of A is then used to solve the system of
   equations A * X = B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the Hermitian matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.
```

```
  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**H *U or A = L*L**H.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i of A is not
        positive definite, so the factorization could not be
        completed, and the solution has not been computed.

SYNOPSIS
   Functions/Subroutines
       subroutine zposvx (FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, EQUED, S, B,
           LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
            ZPOSVX computes the solution to system of linear equations A * X =
           B for PO matrices

Function/Subroutine Documentation
   subroutine zposvx (character FACT, character UPLO, integer N, integer NRHS,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, character EQUED, double precision,
       dimension( * ) S, complex*16, dimension( ldb, * ) B, integer LDB,
       complex*16, dimension( ldx, * ) X, integer LDX, double precision RCOND,
       double precision, dimension( * ) FERR, double precision, dimension( * )
       BERR, complex*16, dimension( * ) WORK, double precision, dimension( * )
       RWORK, integer INFO)
        ZPOSVX computes the solution to system of linear equations A * X = B
       for PO matrices

Purpose:
   ZPOSVX uses the Cholesky factorization A = U**H*U or A = L*L**H to
   compute the solution to a complex system of linear equations
      A * X = B,
   where A is an N-by-N Hermitian positive definite matrix and X and B
   are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.
```

```
Description:

   The following steps are performed:

   1. If FACT = 'E', real scaling factors are computed to equilibrate
      the system:
         diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**H* U,  if UPLO = 'U', or
         A = L * L**H,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   4. The system of equations is solved for X using the factored form of A.

   5. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

   6. If equilibration was used, the matrix X is premultiplied by
     diag(S) so that it solves the original system before equilibration.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF contains the factored form of A.
      If EQUED = 'Y', the matrix A has been equilibrated
      with scaling factors given by S.  A and AF will not
      be modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.
```

```
UPLO
  UPLO is CHARACTER*1
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the Hermitian matrix A, except if FACT = 'F' and
  EQUED = 'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.  A is not modified if
  FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**H *U or A = L*L**H, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored form
  of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**H *U or A = L*L**H of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**H *U or A = L*L**H of the equilibrated
```

```
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Equilibration was done, i.e., A has been replaced by
          diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
  output argument.

S
  S is DOUBLE PRECISION array, dimension (N)
  The scale factors for A; not accessed if EQUED = 'N'.  S is
  an input argument if FACT = 'F'; otherwise, S is an output
  argument.  If FACT = 'F' and EQUED = 'Y', each element of S
  must be positive.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS righthand side matrix B.
  On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y',
  B is overwritten by diag(S) * B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to
  the original system of equations.  Note that if EQUED = 'Y',
  A and B are modified on exit, and the solution to the
  equilibrated system is inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A after equilibration (if done).  If RCOND is less than the
  machine precision (in particular, if RCOND = 0), the matrix
  is singular to working precision.  This condition is
```

```
  indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, and i is
  <= N:  the leading minor of order i of A is
     not positive definite, so the factorization
     could not be completed, and the solution has not
     been computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

     dimension( * ) WORK, double precision, dimension( * ) RWORK, integer
     INFO)
      ZPOSVXX computes the solution to system of linear equations A * X = B
     for PO matrices

Purpose:
   ZPOSVXX uses the Cholesky factorization A = U**T*U or A = L*L**T
   to compute the solution to a complex*16 system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix
   and X and B are N-by-NRHS matrices.

   If requested, both normwise and maximum componentwise error bounds
   are returned. ZPOSVXX will return a solution with a tiny
   guaranteed error (O(eps) where eps is the working machine
   precision) unless the matrix is very ill-conditioned, in which
   case a warning is returned. Relevant condition numbers also are
   calculated and returned.

   ZPOSVXX accepts user-provided factorizations and equilibration
   factors; see the definitions of the FACT and EQUED options.
   Solving with refinement and using a factorization from a previous
   ZPOSVXX call will also produce a solution with either O(eps)
   errors or warnings, but we cannot make that claim for general
   user-provided factorizations and equilibration factors if they
   differ from what ZPOSVXX would itself produce.

Description:

   The following steps are performed:

   1. If FACT = 'E', double precision scaling factors are computed to
      equilibrate the system:

      diag(S)*A*diag(S)     *inv(diag(S))*X = diag(S)*B

      Whether or not the system will be equilibrated depends on the
      scaling of the matrix A, but if equilibration is used, A is
      overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

   2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
      factor the matrix A (after equilibration if FACT = 'E') as
         A = U**T* U,  if UPLO = 'U', or
         A = L * L**T,  if UPLO = 'L',
      where U is an upper triangular matrix and L is a lower triangular
      matrix.

   3. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
```

```
      form of A is used to estimate the condition number of the matrix
      A (see argument RCOND).  If the reciprocal of the condition number
      is less than machine precision, the routine still goes on to solve
      for X and compute error bounds as described below.

   4. The system of equations is solved for X using the factored form of A.

   5. By default (unless PARAMS(LA_LINRX_ITREF_I) is set to zero),
      the routine will use iterative refinement to try to get a small
      error and error bounds.  Refinement calculates the residual to at
      least twice the working precision.

   6. If equilibration was used, the matrix X is premultiplied by
      diag(S) so that it solves the original system before equilibration.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix A is
   supplied on entry, and if not, whether the matrix A should be
   equilibrated before it is factored.
   = 'F':  On entry, AF contains the factored form of A.
      If EQUED is not 'N', the matrix A has been
      equilibrated with scaling factors given by S.
      A and AF are not modified.
   = 'N':  The matrix A will be copied to AF and factored.
   = 'E':  The matrix A will be equilibrated if necessary, then
      copied to AF and factored.

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.
```

```
A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the symmetric matrix A, except if FACT = 'F' and EQUED =
  'Y', then A must contain the equilibrated matrix
  diag(S)*A*diag(S).  If UPLO = 'U', the leading N-by-N upper
  triangular part of A contains the upper triangular part of the
  matrix A, and the strictly lower triangular part of A is not
  referenced.  If UPLO = 'L', the leading N-by-N lower triangular
  part of A contains the lower triangular part of the matrix A, and
  the strictly upper triangular part of A is not referenced.  A is
  not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED =
  'N' on exit.

  On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by
  diag(S)*A*diag(S).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  If FACT = 'F', then AF is an input argument and on entry
  contains the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T, in the same storage
  format as A.  If EQUED .ne. 'N', then AF is the factored
  form of the equilibrated matrix diag(S)*A*diag(S).

  If FACT = 'N', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the original
  matrix A.

  If FACT = 'E', then AF is an output argument and on exit
  returns the triangular factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T of the equilibrated
  matrix A (see the description of A for the form of the
  equilibrated matrix).

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

EQUED
  EQUED is CHARACTER*1
  Specifies the form of equilibration that was done.
  = 'N':  No equilibration (always true if FACT = 'N').
  = 'Y':  Both row and column equilibration, i.e., A has been
          replaced by diag(S) * A * diag(S).
  EQUED is an input argument if FACT = 'F'; otherwise, it is an
```

```
  output argument.

S
  S is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit,
  if EQUED = 'N', B is not modified;
  if EQUED = 'Y', B is overwritten by diag(S)*B;

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0, the N-by-NRHS solution matrix X to the original
  system of equations.  Note that A and B are modified on exit if
  EQUED .ne. 'N', and the solution to the equilibrated system is
  inv(diag(S))*X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

RPVGRW
  RPVGRW is DOUBLE PRECISION
  Reciprocal pivot growth.  On exit, this contains the reciprocal
```

```
  pivot growth factor norm(A)/norm(U). The "max absolute element"
  norm is used.  If this is much less than 1, then the stability of
  the LU factorization of the (equilibrated) matrix A could be poor.
  This also means that the solution X, estimated condition numbers,
  and error bounds could be unreliable. If factorization fails with
  0<INFO<=N, then this contains the reciprocal pivot growth factor
  for the leading INFO columns of A.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
          max_j (abs(XTRUE(j,i) - X(j,i)))
           ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
```

```
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated normwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * dlamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*A, where S scales each row by a power of the
      radix so all absolute row sums of Z are approximately 1.

 ERR_BNDS_COMP
   ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
   For each right-hand side, this array contains information about
   various error bounds and condition numbers corresponding to the
   componentwise relative error, which is defined as follows:

   Componentwise relative error in the ith solution vector:
               abs(XTRUE(j,i) - X(j,i))
          max_j ----------------------
                        abs(X(j,i))

   The array is indexed by the right-hand side i (on which the
   componentwise relative error depends), and the type of error
   information as described below. There currently are up to three
   pieces of information returned for each right-hand side. If
   componentwise accuracy is not requested (PARAMS(3) = 0.0), then
   ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
   the first (:,N_ERR_BNDS) entries are returned.

   The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
   right-hand side.

   The second index in ERR_BNDS_COMP(:,err) contains the following
   three fields:

   err = 1 "Trust/don't trust" boolean. Trust the answer if the
      reciprocal condition number is less than the threshold
      sqrt(n) * dlamch('Epsilon').

   err = 2 "Guaranteed" error bound: The estimated forward error,
      almost certainly within a factor of 10 of the true error
      so long as the next entry is greater than the threshold
      sqrt(n) * dlamch('Epsilon'). This error bound should only
      be trusted if the previous boolean is true.

   err = 3  Reciprocal condition number: Estimated componentwise
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * dlamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
```

```
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the extra-precise refinement algorithm.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
```

```
      guaranteed.
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

SYNOPSIS
   Functions/Subroutines
       double precision function dla_porcond (UPLO, N, A, LDA, AF, LDAF,
           CMODE, C, INFO, WORK, IWORK)
           DLA_PORCOND estimates the Skeel condition number for a symmetric
           positive-definite matrix.

Function/Subroutine Documentation
   double precision function dla_porcond (character UPLO, integer N, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, integer CMODE, double precision,
       dimension( * ) C, integer INFO, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK)
       DLA_PORCOND estimates the Skeel condition number for a symmetric
       positive-definite matrix.

Purpose:
   DLA_PORCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**T*U or A = L*L**T, as computed by DPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is DOUBLE PRECISION array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N).
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dla_porfsx_extended (PREC_TYPE, UPLO, N, NRHS, A, LDA, AF,
           LDAF, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
           ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
           DZ_UB, IGNORE_CWISE, INFO)
           DLA_PORFSX_EXTENDED improves the computed solution to a system of
           linear equations for symmetric or Hermitian positive-definite
           matrices by performing extra-precise iterative refinement and
           provides error bounds and backward error estimates for the
           solution.

       DLA_PORFSX_EXTENDED improves the computed solution to a system of
       linear equations for symmetric or Hermitian positive-definite matrices
       by performing extra-precise iterative refinement and provides error
```

```
       bounds and backward error estimates for the solution.

Purpose:
   DLA_PORFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by DPORFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

   PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by DPOTRF.
```

```
LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is DOUBLE PRECISION array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by DPOTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by DLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
```

```
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                    max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:
```

```
  Componentwise relative error in the ith solution vector:
                     abs(XTRUE(j,i) - X(j,i))
                max_j ----------------------
                            abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.
```

```
DY
  DY is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is DOUBLE PRECISION array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is DOUBLE PRECISION
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is DOUBLE PRECISION
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..
```

```
 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   < 0:  if INFO = -i, the ith argument to DPOTRS had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       double precision function dla_porpvgrw (UPLO, NCOLS, A, LDA, AF, LDAF,
           WORK)
           DLA_PORPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric or Hermitian positive-definite
           matrix.

Function/Subroutine Documentation
   double precision function dla_porpvgrw (character*1 UPLO, integer NCOLS,
```

```
      double precision, dimension( lda, * ) A, integer LDA, double precision,
      dimension( ldaf, * ) AF, integer LDAF, double precision, dimension( * )
      WORK)
      DLA_PORPVGRW computes the reciprocal pivot growth factor
      norm(A)/norm(U) for a symmetric or Hermitian positive-definite matrix.

Purpose:
   DLA_PORPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by DPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 WORK
   WORK is DOUBLE PRECISION array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine dpocon (UPLO, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
           DPOCON

Function/Subroutine Documentation
   subroutine dpocon (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, double precision ANORM, double precision
       RCOND, double precision, dimension( * ) WORK, integer, dimension( * )
       IWORK, integer INFO)
       DPOCON

Purpose:
   DPOCON estimates the reciprocal of the condition number (in the
   1-norm) of a real symmetric positive definite matrix using the
   Cholesky factorization A = U**T*U or A = L*L**T computed by DPOTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by DPOTRF.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

ANORM
  ANORM is DOUBLE PRECISION
  The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dpoequ (N, A, LDA, S, SCOND, AMAX, INFO)
           DPOEQU

Function/Subroutine Documentation
   subroutine dpoequ (integer N, double precision, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) S, double precision
       SCOND, double precision AMAX, integer INFO)
       DPOEQU

Purpose:
   DPOEQU computes row and column scalings intended to equilibrate a
   symmetric positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The N-by-N symmetric positive definite matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is DOUBLE PRECISION array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is DOUBLE PRECISION
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
```

```
  AMAX is DOUBLE PRECISION
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dpoequb (N, A, LDA, S, SCOND, AMAX, INFO)
           DPOEQUB

Function/Subroutine Documentation
   subroutine dpoequb (integer N, double precision, dimension( lda, * ) A,
       integer LDA, double precision, dimension( * ) S, double precision
```

```
      SCOND, double precision AMAX, integer INFO)
      DPOEQUB

Purpose:
   DPOEQU computes row and column scalings intended to equilibrate a
   symmetric positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The N-by-N symmetric positive definite matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is DOUBLE PRECISION array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is DOUBLE PRECISION
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix
   should be scaled.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.

SYNOPSIS
   Functions/Subroutines
       subroutine dporfs (UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,
           FERR, BERR, WORK, IWORK, INFO)
           DPORFS
```

```
Function/Subroutine Documentation
   subroutine dporfs (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldaf, * ) AF, integer LDAF, double precision, dimension(
       ldb, * ) B, integer LDB, double precision, dimension( ldx, * ) X,
       integer LDX, double precision, dimension( * ) FERR, double precision,
       dimension( * ) BERR, double precision, dimension( * ) WORK, integer,
       dimension( * ) IWORK, integer INFO)
       DPORFS

Purpose:
   DPORFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive definite,
   and provides error bounds and backward error estimates for the
   solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading N-by-N lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is DOUBLE PRECISION array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
```

```
  A = U**T*U or A = L*L**T, as computed by DPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DPOTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

```
Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

       double precision, dimension( nrhs, * ) ERR_BNDS_NORM, double precision,
       dimension( nrhs, * ) ERR_BNDS_COMP, integer NPARAMS, double precision,
       dimension( * ) PARAMS, double precision, dimension( * ) WORK, integer,
       dimension( * ) IWORK, integer INFO)
       DPORFSX

Purpose:
   DPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
```

```
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading N-by-N lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
```

```
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is DOUBLE PRECISION array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**T*U or A = L*L**T, as computed by DPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

S
  S is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
```

```
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
            max_j (abs(XTRUE(j,i) - X(j,i)))
             ------------------------------
                   max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
```

```
      reciprocal condition number.  Compared with the threshold
      sqrt(n) * dlamch('Epsilon') to determine if the error
      estimate is "guaranteed". These reciprocal condition
      numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
      appropriately scaled matrix Z.
      Let Z = S*A, where S scales each row by a power of the
      radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
```

```
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension (NPARAMS)
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
        guaranteed.
```

```
   < 0:  If INFO = -i, the i-th argument had an illegal value
   > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
   = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dpotf2 (UPLO, N, A, LDA, INFO)
           DPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
           positive definite matrix (unblocked algorithm).

Function/Subroutine Documentation
   subroutine dpotf2 (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer INFO)
       DPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
       positive definite matrix (unblocked algorithm).

Purpose:
   DPOTF2 computes the Cholesky factorization of a real symmetric
   positive definite matrix A.
```

```
   The factorization has the form
      A = U**T * U ,  if UPLO = 'U', or
      A = L  * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading n by n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**T *U  or A = L*L**T.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, the leading minor of order k is not
        positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dpotrf (UPLO, N, A, LDA, INFO)
           DPOTRF

Function/Subroutine Documentation
   subroutine dpotrf (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer INFO)
       DPOTRF

Purpose:
   DPOTRF computes the Cholesky factorization of a real symmetric
   positive definite matrix A.

   The factorization has the form
      A = U**T * U,  if UPLO = 'U', or
      A = L  * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the block version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
```

```
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
        positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       recursive subroutine dpotrf2 (UPLO, N, A, LDA, INFO)
           DPOTRF2

Function/Subroutine Documentation
   recursive subroutine dpotrf2 (character UPLO, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer INFO)
       DPOTRF2

Purpose:
   DPOTRF2 computes the Cholesky factorization of a real symmetric
   positive definite matrix A using the recursive algorithm.

   The factorization has the form
      A = U**T * U,  if UPLO = 'U', or
      A = L  * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

       [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
   A = [ -----|----- ]  with n1 = n/2
       [  A21 | A22  ]       n2 = n-n1

   The subroutine calls itself to factor A11. Update and scale A21
   or A12, update A22 then calls itself to factor A22.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
```

```
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**T*U or A = L*L**T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
        positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dpotri (UPLO, N, A, LDA, INFO)
           DPOTRI

Function/Subroutine Documentation
   subroutine dpotri (character UPLO, integer N, double precision, dimension(
       lda, * ) A, integer LDA, integer INFO)
       DPOTRI

Purpose:
   DPOTRI computes the inverse of a real symmetric positive definite
   matrix A using the Cholesky factorization A = U**T*U or A = L*L**T
   computed by DPOTRF.

Parameters:
```

```
 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the triangular factor U or L from the Cholesky
   factorization A = U**T*U or A = L*L**T, as computed by DPOTRF.
   On exit, the upper or lower triangle of the (symmetric)
   inverse of A, overwriting the input factor U or L.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the (i,i) element of the factor U or L is
         zero, and the inverse could not be computed.
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dpotrs (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
           DPOTRS

Function/Subroutine Documentation
   subroutine dpotrs (character UPLO, integer N, integer NRHS, double
       precision, dimension( lda, * ) A, integer LDA, double precision,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       DPOTRS

Purpose:
   DPOTRS solves a system of linear equations A*X = B with a symmetric
   positive definite matrix A using the Cholesky factorization
   A = U**T*U or A = L*L**T computed by DPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
```

```
  of the matrix B.  NRHS >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**T*U or A = L*L**T, as computed by DPOTRF.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       real function sla_porcond (UPLO, N, A, LDA, AF, LDAF, CMODE, C, INFO,
           WORK, IWORK)
           SLA_PORCOND estimates the Skeel condition number for a symmetric
           positive-definite matrix.

Function/Subroutine Documentation
   real function sla_porcond (character UPLO, integer N, real, dimension( lda,
       * ) A, integer LDA, real, dimension( ldaf, * ) AF, integer LDAF,
       integer CMODE, real, dimension( * ) C, integer INFO, real, dimension( *
       ) WORK, integer, dimension( * ) IWORK)
       SLA_PORCOND estimates the Skeel condition number for a symmetric
       positive-definite matrix.

Purpose:
   SLA_PORCOND Estimates the Skeel condition number of  op(A) * op2(C)
   where op2 is determined by CMODE as follows
   CMODE =  1    op2(C) = C
   CMODE =  0    op2(C) = I
   CMODE = -1    op2(C) = inv(C)
   The Skeel condition number  cond(A) = norminf( |inv(A)||A| )
   is computed by computing scaling factors R such that
   diag(R)*A*op2(C) is row equilibrated and computing the standard
   infinity-norm condition number.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
AF
  AF is REAL array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**T*U or A = L*L**T, as computed by SPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

CMODE
  CMODE is INTEGER
  Determines op2(C) in the formula op(A) * op2(C) as follows:
  CMODE =  1    op2(C) = C
  CMODE =  0    op2(C) = I
  CMODE = -1    op2(C) = inv(C)

C
  C is REAL array, dimension (N)
  The vector C in the formula op(A) * op2(C).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is REAL array, dimension (3*N).
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (N).
  Workspace.

SYNOPSIS
   Functions/Subroutines
       subroutine sla_porfsx_extended (PREC_TYPE, UPLO, N, NRHS, A, LDA, AF,
           LDAF, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
           ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
           DZ_UB, IGNORE_CWISE, INFO)
           SLA_PORFSX_EXTENDED improves the computed solution to a system of
           linear equations for symmetric or Hermitian positive-definite
           matrices by performing extra-precise iterative refinement and
           provides error bounds and backward error estimates for the
           solution.

Function/Subroutine Documentation

       dimension( * ) DY, real, dimension( * ) Y_TAIL, real RCOND, integer
       ITHRESH, real RTHRESH, real DZ_UB, logical IGNORE_CWISE, integer INFO)
       SLA_PORFSX_EXTENDED improves the computed solution to a system of
       linear equations for symmetric or Hermitian positive-definite matrices
       by performing extra-precise iterative refinement and provides error
       bounds and backward error estimates for the solution.

Purpose:
   SLA_PORFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by SPORFSX to perform iterative refinement.
```

```
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 COLEQU
   COLEQU is LOGICAL
```

```
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is REAL array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by SPOTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by SLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
```

```
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                    max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
```

```
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is REAL array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is REAL array, dimension (N)
  Workspace. This can be the same workspace passed for Y_TAIL.

DY
  DY is REAL array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is REAL array, dimension (N)
```

```
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to SPOTRS had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       real function sla_porpvgrw (UPLO, NCOLS, A, LDA, AF, LDAF, WORK)
           SLA_PORPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric or Hermitian positive-definite
           matrix.

Function/Subroutine Documentation
   real function sla_porpvgrw (character*1 UPLO, integer NCOLS, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * ) AF,
       integer LDAF, real, dimension( * ) WORK)
       SLA_PORPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a symmetric or Hermitian positive-definite matrix.

Purpose:
   SLA_PORPVGRW computes the reciprocal pivot growth factor
```

```
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 WORK
   WORK is REAL array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine spocon (UPLO, N, A, LDA, ANORM, RCOND, WORK, IWORK, INFO)
           SPOCON

Function/Subroutine Documentation
   subroutine spocon (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, real ANORM, real RCOND, real, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
       SPOCON

Purpose:
   SPOCON estimates the reciprocal of the condition number (in the
   1-norm) of a real symmetric positive definite matrix using the
   Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 ANORM
   ANORM is REAL
   The 1-norm (or infinity-norm) of the symmetric matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
   estimate of the 1-norm of inv(A) computed in this routine.
```

```
 WORK
   WORK is REAL array, dimension (3*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

SYNOPSIS
   Functions/Subroutines
       subroutine spoequ (N, A, LDA, S, SCOND, AMAX, INFO)
           SPOEQU

Function/Subroutine Documentation
   subroutine spoequ (integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( * ) S, real SCOND, real AMAX, integer INFO)
       SPOEQU
```

```
Purpose:
   SPOEQU computes row and column scalings intended to equilibrate a
   symmetric positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The N-by-N symmetric positive definite matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is REAL array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is REAL
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
   AMAX is REAL
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix
   should be scaled.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine spoequb (N, A, LDA, S, SCOND, AMAX, INFO)
           SPOEQUB

Function/Subroutine Documentation
   subroutine spoequb (integer N, real, dimension( lda, * ) A, integer LDA,
       real, dimension( * ) S, real SCOND, real AMAX, integer INFO)
       SPOEQUB

Purpose:
   SPOEQU computes row and column scalings intended to equilibrate a
   symmetric positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.
```

```
A
  A is REAL array, dimension (LDA,N)
  The N-by-N symmetric positive definite matrix whose scaling
  factors are to be computed.  Only the diagonal elements of A
  are referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

S
  S is REAL array, dimension (N)
  If INFO = 0, S contains the scale factors for A.

SCOND
  SCOND is REAL
  If INFO = 0, S contains the ratio of the smallest S(i) to
  the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
  large nor too small, it is not worth scaling by S.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sporfs (UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,
           FERR, BERR, WORK, IWORK, INFO)
           SPORFS

Function/Subroutine Documentation
   subroutine sporfs (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldaf, * ) AF,
       integer LDAF, real, dimension( ldb, * ) B, integer LDB, real,
       dimension( ldx, * ) X, integer LDX, real, dimension( * ) FERR, real,
       dimension( * ) BERR, real, dimension( * ) WORK, integer, dimension( * )
       IWORK, integer INFO)
       SPORFS

Purpose:
```

```
  SPORFS improves the computed solution to a system of linear
  equations when the coefficient matrix is symmetric positive definite,
  and provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading N-by-N lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 B
   B is REAL array, dimension (LDB,NRHS)
   The right hand side matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).
```

```
 X
   X is REAL array, dimension (LDX,NRHS)
   On entry, the solution matrix X, as computed by SPOTRS.
   On exit, the improved solution matrix X.

 LDX
   LDX is INTEGER
   The leading dimension of the array X.  LDX >= max(1,N).

 FERR
   FERR is REAL array, dimension (NRHS)
   The estimated forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).  The estimate is as reliable as
   the estimate for RCOND, and is almost always a slight
   overestimate of the true error.

 BERR
   BERR is REAL array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is REAL array, dimension (3*N)

 IWORK
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

       NPARAMS, real, dimension( * ) PARAMS, real, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
       SPORFSX

Purpose:
   SPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading N-by-N lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is REAL array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).
```

```
S
  S is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
```

```
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * slamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*A, where S scales each row by a power of the
     radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
```

```
              abs(XTRUE(j,i) - X(j,i))
         max_j ----------------------
                     abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is REAL array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.
```

```
  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is REAL array, dimension (4*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
     componentwise error is not requested (PARAMS(3) = 0.0) then
     the Jth right-hand side is the first with a normwise error
     bound that is not guaranteed (the smallest J such
     that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
     the Jth right-hand side is the first with either a normwise or
     componentwise error bound that is not guaranteed (the smallest
```

```
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine spotf2 (UPLO, N, A, LDA, INFO)
           SPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
           positive definite matrix (unblocked algorithm).

Function/Subroutine Documentation
   subroutine spotf2 (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer INFO)
       SPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
       positive definite matrix (unblocked algorithm).

Purpose:
   SPOTF2 computes the Cholesky factorization of a real symmetric
   positive definite matrix A.

   The factorization has the form
     A = U**T * U ,  if UPLO = 'U', or
     A = L  * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   symmetric matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
```

```
  The order of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  On entry, the symmetric matrix A.  If UPLO = 'U', the leading
  n by n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n by n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**T *U  or A = L*L**T.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
  > 0: if INFO = k, the leading minor of order k is not
       positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine spotrf (UPLO, N, A, LDA, INFO)
           SPOTRF

Function/Subroutine Documentation
   subroutine spotrf (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer INFO)
       SPOTRF

Purpose:
   SPOTRF computes the Cholesky factorization of a real symmetric
   positive definite matrix A.

   The factorization has the form
      A = U**T * U,  if UPLO = 'U', or
```

```
      A = L  * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the block version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**T*U or A = L*L**T.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the leading minor of order i is not
         positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       recursive subroutine spotrf2 (UPLO, N, A, LDA, INFO)
           SPOTRF2

Function/Subroutine Documentation
   recursive subroutine spotrf2 (character UPLO, integer N, real, dimension(
       lda, * ) A, integer LDA, integer INFO)
       SPOTRF2

Purpose:
   SPOTRF2 computes the Cholesky factorization of a real symmetric
   positive definite matrix A using the recursive algorithm.

   The factorization has the form
      A = U**T * U,  if UPLO = 'U', or
```

```
      A = L  * L**T,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

          [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
      A = [ -----|----- ]  with n1 = n/2
          [  A21 | A22  ]       n2 = n-n1

   The subroutine calls itself to factor A11. Update and scale A21
   or A12, update A22 then call itself to factor A22.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**T*U or A = L*L**T.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the leading minor of order i is not
         positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine spotri (UPLO, N, A, LDA, INFO)
           SPOTRI

Function/Subroutine Documentation
   subroutine spotri (character UPLO, integer N, real, dimension( lda, * ) A,
       integer LDA, integer INFO)
       SPOTRI

Purpose:
   SPOTRI computes the inverse of a real symmetric positive definite
   matrix A using the Cholesky factorization A = U**T*U or A = L*L**T
   computed by SPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   On entry, the triangular factor U or L from the Cholesky
   factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.
   On exit, the upper or lower triangle of the (symmetric)
   inverse of A, overwriting the input factor U or L.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the (i,i) element of the factor U or L is
         zero, and the inverse could not be computed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine spotrs (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
           SPOTRS

Function/Subroutine Documentation
   subroutine spotrs (character UPLO, integer N, integer NRHS, real,
       dimension( lda, * ) A, integer LDA, real, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       SPOTRS

Purpose:
```

```
  SPOTRS solves a system of linear equations A*X = B with a symmetric
  positive definite matrix A using the Cholesky factorization
  A = U**T*U or A = L*L**T computed by SPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       real function cla_porcond_c (UPLO, N, A, LDA, AF, LDAF, C, CAPPLY,
           INFO, WORK, RWORK)
           CLA_PORCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for Hermitian positive-definite matrices.

Function/Subroutine Documentation
   real function cla_porcond_c (character UPLO, integer N, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF, integer
       LDAF, real, dimension( * ) C, logical CAPPLY, integer INFO, complex,
       dimension( * ) WORK, real, dimension( * ) RWORK)
       CLA_PORCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for Hermitian positive-definite matrices.

Purpose:
   CLA_PORCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H*U or A = L*L**H, as computed by CPOTRF.
```

```
 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 C
   C is REAL array, dimension (N)
   The vector C in the formula op(A) * inv(diag(C)).

 CAPPLY
   CAPPLY is LOGICAL
   If .TRUE. then access the vector C in the formula above.

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
   WORK is COMPLEX array, dimension (2*N).
   Workspace.

 RWORK
   RWORK is REAL array, dimension (N).
   Workspace.
```

SYNOPSIS
   Functions/Subroutines
       real function cla_porcond_x (UPLO, N, A, LDA, AF, LDAF, X, INFO, WORK,
           RWORK)
           CLA_PORCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for Hermitian positive-definite matrices.

Function/Subroutine Documentation
   real function cla_porcond_x (character UPLO, integer N, complex, dimension(
       lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF, integer
       LDAF, complex, dimension( * ) X, integer INFO, complex, dimension( * )
       WORK, real, dimension( * ) RWORK)
       CLA_PORCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for Hermitian positive-definite matrices.

Purpose:
   CLA_PORCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX vector.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.
```

```
N
  N is INTEGER
  The number of linear equations, i.e., the order of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

X
  X is COMPLEX array, dimension (N)
  The vector X in the formula op(A) * diag(X).

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  i > 0:  The ith argument is invalid.

WORK
  WORK is COMPLEX array, dimension (2*N).
  Workspace.

RWORK
  RWORK is REAL array, dimension (N).
  Workspace.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cla_porfsx_extended (PREC_TYPE, UPLO, N, NRHS, A, LDA, AF,
           LDAF, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
           ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
           DZ_UB, IGNORE_CWISE, INFO)
           CLA_PORFSX_EXTENDED improves the computed solution to a system of
           linear equations for symmetric or Hermitian positive-definite
           matrices by performing extra-precise iterative refinement and
           provides error bounds and backward error estimates for the
           solution.

       IGNORE_CWISE, integer INFO)
       CLA_PORFSX_EXTENDED improves the computed solution to a system of
       linear equations for symmetric or Hermitian positive-definite matrices
       by performing extra-precise iterative refinement and provides error
       bounds and backward error estimates for the solution.

Purpose:
   CLA_PORFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by CPORFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
```

```
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by CPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 COLEQU
   COLEQU is LOGICAL
   If .TRUE. then column equilibration was done to A before calling
   this routine. This is needed to compute the solution and error
   bounds correctly.
```

```
C
  C is REAL array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by CPOTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).

BERR_OUT
  BERR_OUT is REAL array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by CLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
          max_j (abs(XTRUE(j,i) - X(j,i)))
```

```
          ------------------------------
                 max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                  abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
```

```
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is REAL array, dimension (N)
  Workspace.

DY
  DY is COMPLEX array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
```

```
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is REAL
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
  DZ_UB is REAL
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to CPOTRS had an illegal value

SYNOPSIS
   Functions/Subroutines
```

```
      real function cla_porpvgrw (UPLO, NCOLS, A, LDA, AF, LDAF, WORK)
          CLA_PORPVGRW computes the reciprocal pivot growth factor
          norm(A)/norm(U) for a symmetric or Hermitian positive-definite
          matrix.

Function/Subroutine Documentation
   real function cla_porpvgrw (character*1 UPLO, integer NCOLS, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF,
       integer LDAF, real, dimension( * ) WORK)
       CLA_PORPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a symmetric or Hermitian positive-definite matrix.

Purpose:
   CLA_PORPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by CPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 WORK
   WORK is COMPLEX array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine cpocon (UPLO, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
           CPOCON

Function/Subroutine Documentation
   subroutine cpocon (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, real ANORM, real RCOND, complex, dimension( * ) WORK,
       real, dimension( * ) RWORK, integer INFO)
       CPOCON

Purpose:
   CPOCON estimates the reciprocal of the condition number (in the
   1-norm) of a complex Hermitian positive definite matrix using the
   Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF.
```

```
   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H*U or A = L*L**H, as computed by CPOTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 ANORM
   ANORM is REAL
   The 1-norm (or infinity-norm) of the Hermitian matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
   estimate of the 1-norm of inv(A) computed in this routine.

 WORK
   WORK is COMPLEX array, dimension (2*N)

 RWORK
   RWORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine cpoequ (N, A, LDA, S, SCOND, AMAX, INFO)
           CPOEQU

Function/Subroutine Documentation
   subroutine cpoequ (integer N, complex, dimension( lda, * ) A, integer LDA,
       real, dimension( * ) S, real SCOND, real AMAX, integer INFO)
       CPOEQU

Purpose:
   CPOEQU computes row and column scalings intended to equilibrate a
   Hermitian positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
```

```
  The N-by-N Hermitian positive definite matrix whose scaling
  factors are to be computed.  Only the diagonal elements of A
  are referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

S
  S is REAL array, dimension (N)
  If INFO = 0, S contains the scale factors for A.

SCOND
  SCOND is REAL
  If INFO = 0, S contains the ratio of the smallest S(i) to
  the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
  large nor too small, it is not worth scaling by S.

AMAX
  AMAX is REAL
  Absolute value of largest matrix element.  If AMAX is very
  close to overflow or very close to underflow, the matrix
  should be scaled.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cpoequb (N, A, LDA, S, SCOND, AMAX, INFO)
           CPOEQUB

Function/Subroutine Documentation
   subroutine cpoequb (integer N, complex, dimension( lda, * ) A, integer LDA,
       real, dimension( * ) S, real SCOND, real AMAX, integer INFO)
       CPOEQUB

Purpose:
   CPOEQUB computes row and column scalings intended to equilibrate a
   symmetric positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The N-by-N symmetric positive definite matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
 S
   S is REAL array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is REAL
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
   AMAX is REAL
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix should be scaled.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cporfs (UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,
           FERR, BERR, WORK, RWORK, INFO)
           CPORFS

Function/Subroutine Documentation
   subroutine cporfs (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldaf, * ) AF,
       integer LDAF, complex, dimension( ldb, * ) B, integer LDB, complex,
       dimension( ldx, * ) X, integer LDX, real, dimension( * ) FERR, real,
       dimension( * ) BERR, complex, dimension( * ) WORK, real, dimension( * )
       RWORK, integer INFO)
       CPORFS

Purpose:
   CPORFS improves the computed solution to a system of linear
   equations when the coefficient matrix is Hermitian positive definite,
   and provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
```

```
  = 'U':  Upper triangle of A is stored;
  = 'L':  Lower triangle of A is stored.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  The Hermitian matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CPOTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
```

```
  The leading dimension of the array X.  LDX >= max(1,N).

 FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

 BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

 WORK
  WORK is COMPLEX array, dimension (2*N)

 RWORK
  RWORK is REAL array, dimension (N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

  ITMAX is the maximum number of steps of iterative refinement.
```

       ERR_BNDS_COMP, integer NPARAMS, real, dimension(*) PARAMS, complex,
       dimension( * ) WORK, real, dimension( * ) RWORK, integer INFO)
       CPORFSX

Purpose:
   CPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.
```

```
Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
   before calling this routine. This is needed to compute
   the solution and error bounds correctly.
   = 'N':  No equilibration
   = 'Y':  Both row and column equilibration, i.e., A has been
           replaced by diag(S) * A * diag(S).
           The right hand side B has been changed accordingly.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
   is not referenced.  If UPLO = 'L', the leading N-by-N lower
   triangular part of A contains the lower triangular part of
   the matrix A, and the strictly upper triangular part of A is
   not referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by SPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).
```

```
S
  S is REAL array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is REAL array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
```

```
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * slamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is REAL array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
```

```
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                       abs(X(j,i))
```

The array is indexed by the right-hand side i (on which the componentwise relative error depends), and the type of error information as described below. There currently are up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (PARAMS(3) = 0.0), then ERR_BNDS_COMP is not accessed. If N_ERR_BNDS .LT. 3, then at most the first (:,N_ERR_BNDS) entries are returned.

The first index in ERR_BNDS_COMP(i,:) corresponds to the ith right-hand side.

The second index in ERR_BNDS_COMP(:,err) contains the following three fields:

err = 1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold sqrt(n) * slamch('Epsilon').

err = 2 "Guaranteed" error bound: The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold sqrt(n) * slamch('Epsilon'). This error bound should only be trusted if the previous boolean is true.

err = 3 Reciprocal condition number: Estimated componentwise reciprocal condition number. Compared with the threshold sqrt(n) * slamch('Epsilon') to determine if the error estimate is "guaranteed". These reciprocal condition numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some appropriately scaled matrix Z.
Let Z = S*(A*diag(x)), where x is the solution for the current right-hand side and S scales each row of A*diag(x) by a power of the radix so all absolute row sums of Z are approximately 1.

NPARAMS
NPARAMS is INTEGER
Specifies the number of parameters set in PARAMS. If .LE. 0, the PARAMS array is never referenced and default values are used.

PARAMS
PARAMS is REAL array, dimension NPARAMS
Specifies algorithm parameters. If an entry is .LT. 0.0, then that entry will be filled with default value used for that parameter. Only positions up to NPARAMS are accessed; defaults are used for higher-numbered parameters.

```
  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
  guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
      has been completed, but the factor U is exactly singular, so
      the solution and error bounds could not be computed. RCOND = 0
      is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
      not guaranteed. The solutions corresponding to other right-
      hand sides K with K > J may not be guaranteed as well, but
      only the first such right-hand side is reported. If a small
      componentwise error is not requested (PARAMS(3) = 0.0) then
      the Jth right-hand side is the first with a normwise error
      bound that is not guaranteed (the smallest J such
      that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
      the Jth right-hand side is the first with either a normwise or
      componentwise error bound that is not guaranteed (the smallest
```

```
      J such that either ERR_BNDS_NORM(J,1) = 0.0 or
      ERR_BNDS_COMP(J,1) = 0.0). See the definition of
      ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
      about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cpotf2 (UPLO, N, A, LDA, INFO)
           CPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
           positive definite matrix (unblocked algorithm).

Function/Subroutine Documentation
   subroutine cpotf2 (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer INFO)
       CPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
       positive definite matrix (unblocked algorithm).

Purpose:
   CPOTF2 computes the Cholesky factorization of a complex Hermitian
   positive definite matrix A.

   The factorization has the form
      A = U**H * U ,  if UPLO = 'U', or
      A = L  * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   Hermitian matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
```

```
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX array, dimension (LDA,N)
  On entry, the Hermitian matrix A.  If UPLO = 'U', the leading
  n by n upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading n by n lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**H *U  or A = L*L**H.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
  > 0: if INFO = k, the leading minor of order k is not
       positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cpotrf (UPLO, N, A, LDA, INFO)
           CPOTRF

Function/Subroutine Documentation
   subroutine cpotrf (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer INFO)
       CPOTRF

Purpose:
   CPOTRF computes the Cholesky factorization of a complex Hermitian
   positive definite matrix A.

   The factorization has the form
      A = U**H * U,  if UPLO = 'U', or
```

```
      A = L  * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the block version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the Hermitian matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**H*U or A = L*L**H.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the leading minor of order i is not
         positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       recursive subroutine cpotrf2 (UPLO, N, A, LDA, INFO)
           CPOTRF2

Function/Subroutine Documentation
   recursive subroutine cpotrf2 (character UPLO, integer N, complex,
       dimension( lda, * ) A, integer LDA, integer INFO)
       CPOTRF2

Purpose:
   CPOTRF2 computes the Cholesky factorization of a real symmetric
   positive definite matrix A using the recursive algorithm.

   The factorization has the form
      A = U**H * U,  if UPLO = 'U', or
```

```
      A = L  * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

          [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
      A = [ -----|----- ]  with n1 = n/2
          [  A21 | A22  ]       n2 = n-n1

   The subroutine calls itself to factor A11. Update and scale A21
   or A12, update A22 then calls itself to factor A22.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**H*U or A = L*L**H.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the leading minor of order i is not
         positive definite, and the factorization could not be completed.

SYNOPSIS
   Functions/Subroutines
       subroutine cpotri (UPLO, N, A, LDA, INFO)
           CPOTRI

Function/Subroutine Documentation
   subroutine cpotri (character UPLO, integer N, complex, dimension( lda, * )
       A, integer LDA, integer INFO)
       CPOTRI

Purpose:
   CPOTRI computes the inverse of a complex Hermitian positive definite
   matrix A using the Cholesky factorization A = U**H*U or A = L*L**H
   computed by CPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   On entry, the triangular factor U or L from the Cholesky
```

```
  factorization A = U**H*U or A = L*L**H, as computed by CPOTRF.
  On exit, the upper or lower triangle of the (Hermitian)
  inverse of A, overwriting the input factor U or L.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the (i,i) element of the factor U or L is
        zero, and the inverse could not be computed.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine cpotrs (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
           CPOTRS

Function/Subroutine Documentation
   subroutine cpotrs (character UPLO, integer N, integer NRHS, complex,
       dimension( lda, * ) A, integer LDA, complex, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       CPOTRS

Purpose:
   CPOTRS solves a system of linear equations A*X = B with a Hermitian
   positive definite matrix A using the Cholesky factorization
   A = U**H*U or A = L*L**H computed by CPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H*U or A = L*L**H, as computed by CPOTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 B
```

```
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the right hand side matrix B.
  On exit, the solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_porcond_c (UPLO, N, A, LDA, AF, LDAF, C,
           CAPPLY, INFO, WORK, RWORK)
           ZLA_PORCOND_C computes the infinity norm condition number of
           op(A)*inv(diag(c)) for Hermitian positive-definite matrices.

Function/Subroutine Documentation
   double precision function zla_porcond_c (character UPLO, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, double precision, dimension( * ) C, logical
       CAPPLY, integer INFO, complex*16, dimension( * ) WORK, double
       precision, dimension( * ) RWORK)
       ZLA_PORCOND_C computes the infinity norm condition number of
       op(A)*inv(diag(c)) for Hermitian positive-definite matrices.

Purpose:
   ZLA_PORCOND_C Computes the infinity norm condition number of
   op(A) * inv(diag(C)) where C is a DOUBLE PRECISION vector

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H*U or A = L*L**H, as computed by ZPOTRF.
```

```
 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 C
   C is DOUBLE PRECISION array, dimension (N)
   The vector C in the formula op(A) * inv(diag(C)).

 CAPPLY
   CAPPLY is LOGICAL
   If .TRUE. then access the vector C in the formula above.

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
   WORK is COMPLEX*16 array, dimension (2*N).
   Workspace.

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N).
   Workspace.
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_porcond_x (UPLO, N, A, LDA, AF, LDAF, X,
           INFO, WORK, RWORK)
           ZLA_PORCOND_X computes the infinity norm condition number of
           op(A)*diag(x) for Hermitian positive-definite matrices.

Function/Subroutine Documentation
   double precision function zla_porcond_x (character UPLO, integer N,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, complex*16, dimension( * ) X, integer INFO,
       complex*16, dimension( * ) WORK, double precision, dimension( * )
       RWORK)
       ZLA_PORCOND_X computes the infinity norm condition number of
       op(A)*diag(x) for Hermitian positive-definite matrices.
```

```
Purpose:
   ZLA_PORCOND_X Computes the infinity norm condition number of
   op(A) * diag(X) where X is a COMPLEX*16 vector.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H*U or A = L*L**H, as computed by ZPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 X
   X is COMPLEX*16 array, dimension (N)
   The vector X in the formula op(A) * diag(X).

 INFO
   INFO is INTEGER
   = 0:  Successful exit.
   i > 0:  The ith argument is invalid.

 WORK
   WORK is COMPLEX*16 array, dimension (2*N).
   Workspace.

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N).
   Workspace.

SYNOPSIS
   Functions/Subroutines
       subroutine zla_porfsx_extended (PREC_TYPE, UPLO, N, NRHS, A, LDA, AF,
           LDAF, COLEQU, C, B, LDB, Y, LDY, BERR_OUT, N_NORMS, ERR_BNDS_NORM,
           ERR_BNDS_COMP, RES, AYB, DY, Y_TAIL, RCOND, ITHRESH, RTHRESH,
           DZ_UB, IGNORE_CWISE, INFO)
           ZLA_PORFSX_EXTENDED improves the computed solution to a system of
           linear equations for symmetric or Hermitian positive-definite
           matrices by performing extra-precise iterative refinement and
           provides error bounds and backward error estimates for the
           solution.

      integer INFO)
      ZLA_PORFSX_EXTENDED improves the computed solution to a system of
      linear equations for symmetric or Hermitian positive-definite matrices
      by performing extra-precise iterative refinement and provides error
      bounds and backward error estimates for the solution.

Purpose:
   ZLA_PORFSX_EXTENDED improves the computed solution to a system of
   linear equations by performing extra-precise iterative refinement
   and provides error bounds and backward error estimates for the solution.
   This subroutine is called by ZPORFSX to perform iterative refinement.
   In addition to normwise error bound, the code provides maximum
   componentwise error bound if possible. See comments for ERR_BNDS_NORM
   and ERR_BNDS_COMP for details of the error bounds. Note that this
   subroutine is only resonsible for setting the second fields of
   ERR_BNDS_NORM and ERR_BNDS_COMP.

Parameters:

 PREC_TYPE
   PREC_TYPE is INTEGER
   Specifies the intermediate precision to be used in refinement.
   The value is defined by ILAPREC(P) where P is a CHARACTER and
   P    = 'S':  Single
        = 'D':  Double
        = 'I':  Indigenous
        = 'X', 'E':  Extra

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The number of linear equations, i.e., the order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right-hand-sides, i.e., the number of columns of the
   matrix B.
```

```
A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the N-by-N matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**T*U or A = L*L**T, as computed by ZPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

COLEQU
  COLEQU is LOGICAL
  If .TRUE. then column equilibration was done to A before calling
  this routine. This is needed to compute the solution and error
  bounds correctly.

C
  C is DOUBLE PRECISION array, dimension (N)
  The column scale factors for A. If COLEQU = .FALSE., C
  is not accessed. If C is input, each element of C should be a power
  of the radix to ensure a reliable solution and error estimates.
  Scaling by powers of the radix does not cause rounding errors unless
  the result underflows or overflows. Rounding errors during scaling
  lead to refining with a matrix that is not equivalent to the
  input matrix, producing error estimates that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right-hand-side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

Y
  Y is COMPLEX*16 array, dimension (LDY,NRHS)
  On entry, the solution matrix X, as computed by ZPOTRS.
  On exit, the improved solution matrix Y.

LDY
  LDY is INTEGER
  The leading dimension of the array Y.  LDY >= max(1,N).
```

```
BERR_OUT
  BERR_OUT is DOUBLE PRECISION array, dimension (NRHS)
  On exit, BERR_OUT(j) contains the componentwise relative backward
  error for right-hand-side j from the formula
  max(i) ( abs(RES(i)) / ( abs(op(A_s))*abs(Y) + abs(B_s) )(i) )
  where abs(Z) is the componentwise absolute value of the matrix
  or vector Z. This is computed by ZLA_LIN_BERR.

N_NORMS
  N_NORMS is INTEGER
  Determines which error bounds to return (see ERR_BNDS_NORM
  and ERR_BNDS_COMP).
  If N_NORMS >= 1 return normwise error bounds.
  If N_NORMS >= 2 return componentwise error bounds.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
            ------------------------------
                  max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
```

```
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
            max_j ----------------------
                       abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.

  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * slamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * slamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * slamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*(A*diag(x)), where x is the solution for the
    current right-hand side and S scales each row of
```

```
    A*diag(x) by a power of the radix so all absolute row
    sums of Z are approximately 1.

  This subroutine is only responsible for setting the second field above.

RES
  RES is COMPLEX*16 array, dimension (N)
  Workspace to hold the intermediate residual.

AYB
  AYB is DOUBLE PRECISION array, dimension (N)
  Workspace.

DY
  DY is COMPLEX*16 PRECISION array, dimension (N)
  Workspace to hold the intermediate solution.

Y_TAIL
  Y_TAIL is COMPLEX*16 array, dimension (N)
  Workspace to hold the trailing bits of the intermediate solution.

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

ITHRESH
  ITHRESH is INTEGER
  The maximum number of residual computations allowed for
  refinement. The default is 10. For 'aggressive' set to 100 to
  permit convergence using approximate factorizations or
  factorizations other than LU. If the factorization uses a
  technique other than Gaussian elimination, the guarantees in
  ERR_BNDS_NORM and ERR_BNDS_COMP may no longer be trustworthy.

RTHRESH
  RTHRESH is DOUBLE PRECISION
  Determines when to stop refinement if the error estimate stops
  decreasing. Refinement will stop when the next solution no longer
  satisfies norm(dx_{i+1}) < RTHRESH * norm(dx_i) where norm(Z) is
  the infinity norm of Z. RTHRESH satisfies 0 < RTHRESH <= 1. The
  default value is 0.5. For 'aggressive' set to 0.9 to permit
  convergence on extremely ill-conditioned matrices. See LAWN 165
  for more details.

DZ_UB
```

```
  DZ_UB is DOUBLE PRECISION
  Determines when to start considering componentwise convergence.
  Componentwise convergence is only considered after each component
  of the solution Y is stable, which we definte as the relative
  change in each component being less than DZ_UB. The default value
  is 0.25, requiring the first bit to be stable. See LAWN 165 for
  more details.

 IGNORE_CWISE
  IGNORE_CWISE is LOGICAL
  If .TRUE. then ignore componentwise convergence. Default value
  is .FALSE..

 INFO
  INFO is INTEGER
  = 0:  Successful exit.
  < 0:  if INFO = -i, the ith argument to ZPOTRS had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       double precision function zla_porpvgrw (UPLO, NCOLS, A, LDA, AF, LDAF,
           WORK)
           ZLA_PORPVGRW computes the reciprocal pivot growth factor
           norm(A)/norm(U) for a symmetric or Hermitian positive-definite
           matrix.

Function/Subroutine Documentation
   double precision function zla_porpvgrw (character*1 UPLO, integer NCOLS,
       complex*16, dimension( lda, * ) A, integer LDA, complex*16, dimension(
       ldaf, * ) AF, integer LDAF, double precision, dimension( * ) WORK)
       ZLA_PORPVGRW computes the reciprocal pivot growth factor
       norm(A)/norm(U) for a symmetric or Hermitian positive-definite matrix.

Purpose:
   ZLA_PORPVGRW computes the reciprocal pivot growth factor
   norm(A)/norm(U). The "max absolute element" norm is used. If this is
   much less than 1, the stability of the LU factorization of the
   (equilibrated) matrix A could be poor. This also means that the
   solution X, estimated condition numbers, and error bounds could be
   unreliable.

Parameters:
```

```
 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 NCOLS
   NCOLS is INTEGER
   The number of columns of the matrix A. NCOLS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the N-by-N matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 AF
   AF is COMPLEX*16 array, dimension (LDAF,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**T*U or A = L*L**T, as computed by ZPOTRF.

 LDAF
   LDAF is INTEGER
   The leading dimension of the array AF.  LDAF >= max(1,N).

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpocon (UPLO, N, A, LDA, ANORM, RCOND, WORK, RWORK, INFO)
           ZPOCON

Function/Subroutine Documentation
   subroutine zpocon (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, double precision ANORM, double precision RCOND,
       complex*16, dimension( * ) WORK, double precision, dimension( * )
       RWORK, integer INFO)
       ZPOCON

Purpose:
   ZPOCON estimates the reciprocal of the condition number (in the
   1-norm) of a complex Hermitian positive definite matrix using the
   Cholesky factorization A = U**H*U or A = L*L**H computed by ZPOTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H*U or A = L*L**H, as computed by ZPOTRF.

 LDA
```

```
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

ANORM
  ANORM is DOUBLE PRECISION
  The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpoequ (N, A, LDA, S, SCOND, AMAX, INFO)
           ZPOEQU

Function/Subroutine Documentation
   subroutine zpoequ (integer N, complex*16, dimension( lda, * ) A, integer
       LDA, double precision, dimension( * ) S, double precision SCOND, double
       precision AMAX, integer INFO)
       ZPOEQU

Purpose:
   ZPOEQU computes row and column scalings intended to equilibrate a
   Hermitian positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The N-by-N Hermitian positive definite matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is DOUBLE PRECISION array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is DOUBLE PRECISION
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
```

```
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix should be scaled.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpoequb (N, A, LDA, S, SCOND, AMAX, INFO)
```

```
          ZPOEQUB

Function/Subroutine Documentation
   subroutine zpoequb (integer N, complex*16, dimension( lda, * ) A, integer
       LDA, double precision, dimension( * ) S, double precision SCOND, double
       precision AMAX, integer INFO)
       ZPOEQUB

Purpose:
   ZPOEQUB computes row and column scalings intended to equilibrate a
   symmetric positive definite matrix A and reduce its condition number
   (with respect to the two-norm).  S contains the scale factors,
   S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with
   elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal.  This
   choice of S puts the condition number of B within a factor N of the
   smallest possible condition number over all possible diagonal scalings.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The N-by-N symmetric positive definite matrix whose scaling
   factors are to be computed.  Only the diagonal elements of A
   are referenced.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 S
   S is DOUBLE PRECISION array, dimension (N)
   If INFO = 0, S contains the scale factors for A.

 SCOND
   SCOND is DOUBLE PRECISION
   If INFO = 0, S contains the ratio of the smallest S(i) to
   the largest S(i).  If SCOND >= 0.1 and AMAX is neither too
   large nor too small, it is not worth scaling by S.

 AMAX
   AMAX is DOUBLE PRECISION
   Absolute value of largest matrix element.  If AMAX is very
   close to overflow or very close to underflow, the matrix should be scaled.

 INFO
   INFO is INTEGER
```

```
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an illegal value
> 0:  if INFO = i, the i-th diagonal element is nonpositive.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zporfs (UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,
           FERR, BERR, WORK, RWORK, INFO)
           ZPORFS

Function/Subroutine Documentation
   subroutine zporfs (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldaf, * )
       AF, integer LDAF, complex*16, dimension( ldb, * ) B, integer LDB,
       complex*16, dimension( ldx, * ) X, integer LDX, double precision,
       dimension( * ) FERR, double precision, dimension( * ) BERR, complex*16,
       dimension( * ) WORK, double precision, dimension( * ) RWORK, integer
       INFO)
       ZPORFS

Purpose:
   ZPORFS improves the computed solution to a system of linear
   equations when the coefficient matrix is Hermitian positive definite,
   and provides error bounds and backward error estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The Hermitian matrix A.  If UPLO = 'U', the leading N-by-N
   upper triangular part of A contains the upper triangular part
   of the matrix A, and the strictly lower triangular part of A
```

```
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**H*U or A = L*L**H, as computed by ZPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZPOTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
```

```
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX*16 array, dimension (2*N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

       ) RWORK, integer INFO)
       ZPORFSX

Purpose:
   ZPORFSX improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive
   definite, and provides error bounds and backward error estimates
   for the solution.  In addition to normwise error bound, the code
   provides maximum componentwise error bound if possible.  See
   comments for ERR_BNDS_NORM and ERR_BNDS_COMP for details of the
   error bounds.

   The original system of linear equations may have been equilibrated
   before calling this routine, as described by arguments EQUED and S
   below. In this case, the solution and error bounds returned are
   for the original unequilibrated system.

   Some optional parameters are bundled in the PARAMS array.  These
   settings determine how refinement is performed, but often the
   defaults are acceptable.  If the defaults are acceptable, users
   can pass NPARAMS = 0 which prevents the source code from accessing
   the PARAMS argument.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 EQUED
   EQUED is CHARACTER*1
   Specifies the form of equilibration that was done to A
```

```
  before calling this routine. This is needed to compute
  the solution and error bounds correctly.
  = 'N':  No equilibration
  = 'Y':  Both row and column equilibration, i.e., A has been
          replaced by diag(S) * A * diag(S).
          The right hand side B has been changed accordingly.

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  The symmetric matrix A.  If UPLO = 'U', the leading N-by-N
  upper triangular part of A contains the upper triangular part
  of the matrix A, and the strictly lower triangular part of A
  is not referenced.  If UPLO = 'L', the leading N-by-N lower
  triangular part of A contains the lower triangular part of
  the matrix A, and the strictly upper triangular part of A is
  not referenced.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

AF
  AF is COMPLEX*16 array, dimension (LDAF,N)
  The triangular factor U or L from the Cholesky factorization
  A = U**T*U or A = L*L**T, as computed by DPOTRF.

LDAF
  LDAF is INTEGER
  The leading dimension of the array AF.  LDAF >= max(1,N).

S
  S is DOUBLE PRECISION array, dimension (N)
  The row scale factors for A.  If EQUED = 'Y', A is multiplied on
  the left and right by diag(S).  S is an input argument if FACT =
  'F'; otherwise, S is an output argument.  If FACT = 'F' and EQUED
  = 'Y', each element of S must be positive.  If S is output, each
  element of S is a power of the radix. If S is input, each element
  of S should be a power of the radix to ensure a reliable solution
  and error estimates. Scaling by powers of the radix does not cause
  rounding errors unless the result underflows or overflows.
  Rounding errors during scaling lead to refining with a matrix that
```

```
  is not equivalent to the input matrix, producing error estimates
  that may not be reliable.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGETRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  Reciprocal scaled condition number.  This is an estimate of the
  reciprocal Skeel condition number of the matrix A after
  equilibration (if done).  If this is less than the machine
  precision (in particular, if it is zero), the matrix is singular
  to working precision.  Note that the error may still be small even
  if this number is very small and the matrix appears ill-conditioned.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  Componentwise relative backward error.  This is the
  componentwise relative backward error of each solution vector X(j)
  (i.e., the smallest relative change in any element of A or B that
  makes X(j) an exact solution).

N_ERR_BNDS
  N_ERR_BNDS is INTEGER
  Number of error bounds to return for each right hand side
  and each type (normwise or componentwise).  See ERR_BNDS_NORM and
  ERR_BNDS_COMP below.

ERR_BNDS_NORM
  ERR_BNDS_NORM is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  normwise relative error, which is defined as follows:

  Normwise relative error in the ith solution vector:
           max_j (abs(XTRUE(j,i) - X(j,i)))
```

```
            -----------------------------
                   max_j abs(X(j,i))

  The array is indexed by the type of error information as described
  below. There currently are up to three pieces of information
  returned.

  The first index in ERR_BNDS_NORM(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_NORM(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
    reciprocal condition number is less than the threshold
    sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
    almost certainly within a factor of 10 of the true error
    so long as the next entry is greater than the threshold
    sqrt(n) * dlamch('Epsilon'). This error bound should only
    be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated normwise
    reciprocal condition number.  Compared with the threshold
    sqrt(n) * dlamch('Epsilon') to determine if the error
    estimate is "guaranteed". These reciprocal condition
    numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
    appropriately scaled matrix Z.
    Let Z = S*A, where S scales each row by a power of the
    radix so all absolute row sums of Z are approximately 1.

ERR_BNDS_COMP
  ERR_BNDS_COMP is DOUBLE PRECISION array, dimension (NRHS, N_ERR_BNDS)
  For each right-hand side, this array contains information about
  various error bounds and condition numbers corresponding to the
  componentwise relative error, which is defined as follows:

  Componentwise relative error in the ith solution vector:
                 abs(XTRUE(j,i) - X(j,i))
           max_j ----------------------
                        abs(X(j,i))

  The array is indexed by the right-hand side i (on which the
  componentwise relative error depends), and the type of error
  information as described below. There currently are up to three
  pieces of information returned for each right-hand side. If
  componentwise accuracy is not requested (PARAMS(3) = 0.0), then
  ERR_BNDS_COMP is not accessed.  If N_ERR_BNDS .LT. 3, then at most
  the first (:,N_ERR_BNDS) entries are returned.
```

```
  The first index in ERR_BNDS_COMP(i,:) corresponds to the ith
  right-hand side.

  The second index in ERR_BNDS_COMP(:,err) contains the following
  three fields:

  err = 1 "Trust/don't trust" boolean. Trust the answer if the
     reciprocal condition number is less than the threshold
     sqrt(n) * dlamch('Epsilon').

  err = 2 "Guaranteed" error bound: The estimated forward error,
     almost certainly within a factor of 10 of the true error
     so long as the next entry is greater than the threshold
     sqrt(n) * dlamch('Epsilon'). This error bound should only
     be trusted if the previous boolean is true.

  err = 3  Reciprocal condition number: Estimated componentwise
     reciprocal condition number.  Compared with the threshold
     sqrt(n) * dlamch('Epsilon') to determine if the error
     estimate is "guaranteed". These reciprocal condition
     numbers are 1 / (norm(Z^{-1},inf) * norm(Z,inf)) for some
     appropriately scaled matrix Z.
     Let Z = S*(A*diag(x)), where x is the solution for the
     current right-hand side and S scales each row of
     A*diag(x) by a power of the radix so all absolute row
     sums of Z are approximately 1.

NPARAMS
  NPARAMS is INTEGER
  Specifies the number of parameters set in PARAMS.  If .LE. 0, the
  PARAMS array is never referenced and default values are used.

PARAMS
  PARAMS is DOUBLE PRECISION array, dimension NPARAMS
  Specifies algorithm parameters.  If an entry is .LT. 0.0, then
  that entry will be filled with default value used for that
  parameter.  Only positions up to NPARAMS are accessed; defaults
  are used for higher-numbered parameters.

  PARAMS(LA_LINRX_ITREF_I = 1) : Whether to perform iterative
  refinement or not.
  Default: 1.0D+0
  = 0.0 : No refinement is performed, and no error bounds are computed.
  = 1.0 : Use the double-precision refinement algorithm,
          possibly with doubled-single computations if the
          compilation environment does not support DOUBLE PRECISION.
  (other values are reserved for future use)

  PARAMS(LA_LINRX_ITHRESH_I = 2) : Maximum number of residual
```

```
  computations allowed for refinement.
  Default: 10
  Aggressive: Set to 100 to permit convergence using approximate
              factorizations or factorizations other than LU. If
              the factorization uses a technique other than
              Gaussian elimination, the guarantees in
              err_bnds_norm and err_bnds_comp may no longer be trustworthy.

  PARAMS(LA_LINRX_CWISE_I = 3) : Flag determining if the code
  will attempt to find a solution with small componentwise
  relative error in the double-precision algorithm.  Positive
  is true, 0.0 is false.
  Default: 1.0 (attempt componentwise convergence)

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  Successful exit. The solution to every right-hand side is
     guaranteed.
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0 and <= N:  U(INFO,INFO) is exactly zero.  The factorization
     has been completed, but the factor U is exactly singular, so
     the solution and error bounds could not be computed. RCOND = 0
     is returned.
  = N+J: The solution corresponding to the Jth right-hand side is
     not guaranteed. The solutions corresponding to other right-
     hand sides K with K > J may not be guaranteed as well, but
     only the first such right-hand side is reported. If a small
     componentwise error is not requested (PARAMS(3) = 0.0) then
     the Jth right-hand side is the first with a normwise error
     bound that is not guaranteed (the smallest J such
     that ERR_BNDS_NORM(J,1) = 0.0). By default (PARAMS(3) = 1.0)
     the Jth right-hand side is the first with either a normwise or
     componentwise error bound that is not guaranteed (the smallest
     J such that either ERR_BNDS_NORM(J,1) = 0.0 or
     ERR_BNDS_COMP(J,1) = 0.0). See the definition of
     ERR_BNDS_NORM(:,1) and ERR_BNDS_COMP(:,1). To get information
     about all of the right-hand sides check ERR_BNDS_NORM or ERR_BNDS_COMP.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine zpotf2 (UPLO, N, A, LDA, INFO)
           ZPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
           positive definite matrix (unblocked algorithm).

Function/Subroutine Documentation
   subroutine zpotf2 (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer INFO)
       ZPOTF2 computes the Cholesky factorization of a symmetric/Hermitian
       positive definite matrix (unblocked algorithm).

Purpose:
   ZPOTF2 computes the Cholesky factorization of a complex Hermitian
   positive definite matrix A.

   The factorization has the form
      A = U**H * U ,  if UPLO = 'U', or
      A = L  * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the unblocked version of the algorithm, calling Level 2 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the upper or lower triangular part of the
   Hermitian matrix A is stored.
   = 'U':  Upper triangular
   = 'L':  Lower triangular

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the Hermitian matrix A.  If UPLO = 'U', the leading
   n by n upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
```

```
   leading n by n lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**H *U  or A = L*L**H.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, the leading minor of order k is not
        positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpotrf (UPLO, N, A, LDA, INFO)
           ZPOTRF

Function/Subroutine Documentation
   subroutine zpotrf (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer INFO)
       ZPOTRF

Purpose:
   ZPOTRF computes the Cholesky factorization of a complex Hermitian
   positive definite matrix A.

   The factorization has the form
      A = U**H * U,  if UPLO = 'U', or
      A = L  * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the block version of the algorithm, calling Level 3 BLAS.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.
```

```
N
  N is INTEGER
  The order of the matrix A.  N >= 0.

A
  A is COMPLEX*16 array, dimension (LDA,N)
  On entry, the Hermitian matrix A.  If UPLO = 'U', the leading
  N-by-N upper triangular part of A contains the upper
  triangular part of the matrix A, and the strictly lower
  triangular part of A is not referenced.  If UPLO = 'L', the
  leading N-by-N lower triangular part of A contains the lower
  triangular part of the matrix A, and the strictly upper
  triangular part of A is not referenced.

  On exit, if INFO = 0, the factor U or L from the Cholesky
  factorization A = U**H *U or A = L*L**H.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
        positive definite, and the factorization could not be completed.
```

SYNOPSIS
   Functions/Subroutines
       recursive subroutine zpotrf2 (UPLO, N, A, LDA, INFO)
           ZPOTRF2

Function/Subroutine Documentation
   recursive subroutine zpotrf2 (character UPLO, integer N, complex*16,
       dimension( lda, * ) A, integer LDA, integer INFO)
       ZPOTRF2

Purpose:
   ZPOTRF2 computes the Cholesky factorization of a real symmetric
   positive definite matrix A using the recursive algorithm.

   The factorization has the form
      A = U**H * U,  if UPLO = 'U', or
      A = L  * L**H,  if UPLO = 'L',
   where U is an upper triangular matrix and L is lower triangular.

   This is the recursive version of the algorithm. It divides
   the matrix into four submatrices:

           [  A11 | A12  ]  where A11 is n1 by n1 and A22 is n2 by n2
      A = [ -----|----- ]  with n1 = n/2
```

```
          [  A21 | A22  ]       n2 = n-n1

   The subroutine calls itself to factor A11. Update and scale A21
   or A12, update A22 then call itself to factor A22.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the symmetric matrix A.  If UPLO = 'U', the leading
   N-by-N upper triangular part of A contains the upper
   triangular part of the matrix A, and the strictly lower
   triangular part of A is not referenced.  If UPLO = 'L', the
   leading N-by-N lower triangular part of A contains the lower
   triangular part of the matrix A, and the strictly upper
   triangular part of A is not referenced.

   On exit, if INFO = 0, the factor U or L from the Cholesky
   factorization A = U**H*U or A = L*L**H.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, the leading minor of order i is not
         positive definite, and the factorization could not be completed.

SYNOPSIS
   Functions/Subroutines
       subroutine zpotri (UPLO, N, A, LDA, INFO)
           ZPOTRI

Function/Subroutine Documentation
   subroutine zpotri (character UPLO, integer N, complex*16, dimension( lda, *
       ) A, integer LDA, integer INFO)
       ZPOTRI

Purpose:
   ZPOTRI computes the inverse of a complex Hermitian positive definite
   matrix A using the Cholesky factorization A = U**H*U or A = L*L**H
   computed by ZPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   On entry, the triangular factor U or L from the Cholesky
   factorization A = U**H*U or A = L*L**H, as computed by ZPOTRF.
   On exit, the upper or lower triangle of the (Hermitian)
   inverse of A, overwriting the input factor U or L.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

SYNOPSIS
   Functions/Subroutines
       subroutine zpotrs (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
           ZPOTRS

Function/Subroutine Documentation
   subroutine zpotrs (character UPLO, integer N, integer NRHS, complex*16,
       dimension( lda, * ) A, integer LDA, complex*16, dimension( ldb, * ) B,
       integer LDB, integer INFO)
       ZPOTRS

Purpose:
   ZPOTRS solves a system of linear equations A*X = B with a Hermitian
   positive definite matrix A using the Cholesky factorization
   A = U**H * U or A = L * L**H computed by ZPOTRF.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  Upper triangle of A is stored;
   = 'L':  Lower triangle of A is stored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 A
   A is COMPLEX*16 array, dimension (LDA,N)
   The triangular factor U or L from the Cholesky factorization
   A = U**H * U or A = L * L**H, as computed by ZPOTRF.

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,N).

 B
   B is COMPLEX*16 array, dimension (LDB,NRHS)
   On entry, the right hand side matrix B.
   On exit, the solution matrix X.

 LDB
```

```
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgtsv (N, NRHS, DL, D, DU, B, LDB, INFO)
            DGTSV computes the solution to system of linear equations A * X =
           B for GT matrices

Function/Subroutine Documentation
   subroutine dgtsv (integer N, integer NRHS, double precision, dimension( * )
       DL, double precision, dimension( * ) D, double precision, dimension( *
       ) DU, double precision, dimension( ldb, * ) B, integer LDB, integer
       INFO)
        DGTSV computes the solution to system of linear equations A * X = B
       for GT matrices

Purpose:
   DGTSV  solves the equation

   A*X = B,

   where A is an n by n tridiagonal matrix, by Gaussian elimination with
   partial pivoting.

   Note that the equation  A**T*X = B  may be solved by interchanging the
   order of the arguments DU and DL.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is DOUBLE PRECISION array, dimension (N-1)
   On entry, DL must contain the (n-1) sub-diagonal elements of A.

 On exit, DL is overwritten by the (n-2) elements of the

   the LU factorization of A, in DL(1), ..., DL(n-2).

 D
```

```
  D is DOUBLE PRECISION array, dimension (N)
  On entry, D must contain the diagonal elements of A.

  On exit, D is overwritten by the n diagonal elements of U.

DU
  DU is DOUBLE PRECISION array, dimension (N-1)
  On entry, DU must contain the (n-1) super-diagonal elements of A.

  On exit, DU is overwritten by the (n-1) elements of the first
  super-diagonal of U.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N by NRHS matrix of right hand side matrix B.
  On exit, if INFO = 0, the N by NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, U(i,i) is exactly zero, and the solution
       has not been computed.  The factorization has not been
       completed unless i = N.
```

       double precision RCOND, double precision, dimension( * ) FERR, double
       precision, dimension( * ) BERR, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
        DGTSVX computes the solution to system of linear equations A * X = B
       for GT matrices

Purpose:
   DGTSVX uses the LU factorization to compute the solution to a real
   system of linear equations A * X = B or A**T * X = B,
   where A is a tridiagonal matrix of order N and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the LU decomposition is used to factor the matrix A
      as A = L * U, where L is a product of permutation and unit lower
      bidiagonal matrices and U is upper triangular with nonzeros in
      only the main diagonal and first two superdiagonals.

   2. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
```

```
  = 'F':  DLF, DF, DUF, DU2, and IPIV contain the factored
     form of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV
     will not be modified.
  = 'N':  The matrix will be copied to DLF, DF, and DUF
     and factored.

TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

DL
  DL is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) subdiagonal elements of A.

D
  D is DOUBLE PRECISION array, dimension (N)
  The n diagonal elements of A.

DU
  DU is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) superdiagonal elements of A.

DLF
  DLF is DOUBLE PRECISION array, dimension (N-1)
  If FACT = 'F', then DLF is an input argument and on entry
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A as computed by DGTTRF.

  If FACT = 'N', then DLF is an output argument and on exit
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A.

DF
  DF is DOUBLE PRECISION array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.
```

```
  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.

DUF
  DUF is DOUBLE PRECISION array, dimension (N-1)
  If FACT = 'F', then DUF is an input argument and on entry
  contains the (n-1) elements of the first superdiagonal of U.

  If FACT = 'N', then DUF is an output argument and on exit
  contains the (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is DOUBLE PRECISION array, dimension (N-2)
  If FACT = 'F', then DU2 is an input argument and on entry
  contains the (n-2) elements of the second superdiagonal of U.

  If FACT = 'N', then DU2 is an output argument and on exit
  contains the (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the LU factorization of A as
  computed by DGTTRF.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the LU factorization of A;
  row i of the matrix was interchanged with row IPIV(i).
  IPIV(i) will always be either i or i+1; IPIV(i) = i indicates
  a row interchange was not required.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
```

```
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  U(i,i) is exactly zero.  The factorization
     has not been completed unless i = N, but the
     factor U is exactly singular, so the solution
     and error bounds could not be computed.
     RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
    there are a number of situations where the
    computed solution can be more accurate than the
    value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine sgtsv (N, NRHS, DL, D, DU, B, LDB, INFO)
            SGTSV computes the solution to system of linear equations A * X =
           B for GT matrices

Function/Subroutine Documentation
   subroutine sgtsv (integer N, integer NRHS, real, dimension( * ) DL, real,
       dimension( * ) D, real, dimension( * ) DU, real, dimension( ldb, * ) B,
       integer LDB, integer INFO)
        SGTSV computes the solution to system of linear equations A * X = B
       for GT matrices

Purpose:
   SGTSV  solves the equation

   A*X = B,

   where A is an n by n tridiagonal matrix, by Gaussian elimination with
   partial pivoting.

   Note that the equation  A**T*X = B  may be solved by interchanging the
   order of the arguments DU and DL.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is REAL array, dimension (N-1)
   On entry, DL must contain the (n-1) sub-diagonal elements of A.

   On exit, DL is overwritten by the (n-2) elements of the
   second super-diagonal of the upper triangular matrix U from
   the LU factorization of A, in DL(1), ..., DL(n-2).

 D
   D is REAL array, dimension (N)
```

```
  On entry, D must contain the diagonal elements of A.

  On exit, D is overwritten by the n diagonal elements of U.

DU
  DU is REAL array, dimension (N-1)
  On entry, DU must contain the (n-1) super-diagonal elements of A.

  On exit, DU is overwritten by the (n-1) elements of the first
  super-diagonal of U.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N by NRHS matrix of right hand side matrix B.
  On exit, if INFO = 0, the N by NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, U(i,i) is exactly zero, and the solution
       has not been computed.  The factorization has not been
       completed unless i = N.
```

       dimension( * ) BERR, real, dimension( * ) WORK, integer, dimension( * )
       IWORK, integer INFO)
        SGTSVX computes the solution to system of linear equations A * X = B
       for GT matrices

Purpose:
   SGTSVX uses the LU factorization to compute the solution to a real
   system of linear equations A * X = B or A**T * X = B,
   where A is a tridiagonal matrix of order N and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the LU decomposition is used to factor the matrix A
      as A = L * U, where L is a product of permutation and unit lower
      bidiagonal matrices and U is upper triangular with nonzeros in
      only the main diagonal and first two superdiagonals.

   2. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  DLF, DF, DUF, DU2, and IPIV contain the factored
      form of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV
```

```
     will not be modified.
  = 'N':  The matrix will be copied to DLF, DF, and DUF
     and factored.

TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

DL
  DL is REAL array, dimension (N-1)
  The (n-1) subdiagonal elements of A.

D
  D is REAL array, dimension (N)
  The n diagonal elements of A.

DU
  DU is REAL array, dimension (N-1)
  The (n-1) superdiagonal elements of A.

DLF
  DLF is REAL array, dimension (N-1)
  If FACT = 'F', then DLF is an input argument and on entry
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A as computed by SGTTRF.

  If FACT = 'N', then DLF is an output argument and on exit
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A.

DF
  DF is REAL array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.

  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the upper triangular
```

```
  matrix U from the LU factorization of A.

DUF
  DUF is REAL array, dimension (N-1)
  If FACT = 'F', then DUF is an input argument and on entry
  contains the (n-1) elements of the first superdiagonal of U.

  If FACT = 'N', then DUF is an output argument and on exit
  contains the (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is REAL array, dimension (N-2)
  If FACT = 'F', then DU2 is an input argument and on entry
  contains the (n-2) elements of the second superdiagonal of U.

  If FACT = 'N', then DU2 is an output argument and on exit
  contains the (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the LU factorization of A as
  computed by SGTTRF.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the LU factorization of A;
  row i of the matrix was interchanged with row IPIV(i).
  IPIV(i) will always be either i or i+1; IPIV(i) = i indicates
  a row interchange was not required.

B
  B is REAL array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
```

```
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  U(i,i) is exactly zero.  The factorization
     has not been completed unless i = N, but the
     factor U is exactly singular, so the solution
     and error bounds could not be computed.
     RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine cgtsv (N, NRHS, DL, D, DU, B, LDB, INFO)
            CGTSV computes the solution to system of linear equations A * X =
           B for GT matrices

Function/Subroutine Documentation
   subroutine cgtsv (integer N, integer NRHS, complex, dimension( * ) DL,
       complex, dimension( * ) D, complex, dimension( * ) DU, complex,
       dimension( ldb, * ) B, integer LDB, integer INFO)
        CGTSV computes the solution to system of linear equations A * X = B
       for GT matrices

Purpose:
   CGTSV  solves the equation

     A*X = B,

   where A is an N-by-N tridiagonal matrix, by Gaussian elimination with
   partial pivoting.

   Note that the equation  A**T *X = B  may be solved by interchanging the
   order of the arguments DU and DL.

 Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX array, dimension (N-1)
   On entry, DL must contain the (n-1) subdiagonal elements of A.
   On exit, DL is overwritten by the (n-2) elements of the
   second superdiagonal of the upper triangular matrix U from
   the LU factorization of A, in DL(1), ..., DL(n-2).

 D
   D is COMPLEX array, dimension (N)
   On entry, D must contain the diagonal elements of A.
```

```
  On exit, D is overwritten by the n diagonal elements of U.

DU
  DU is COMPLEX array, dimension (N-1)
  On entry, DU must contain the (n-1) superdiagonal elements of A.
  On exit, DU is overwritten by the (n-1) elements of the first
  superdiagonal of U.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero, and the solution
        has not been computed.  The factorization has not been
        completed unless i = N.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgtsvx (FACT, TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2,
           IPIV, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK, INFO)
            CGTSVX computes the solution to system of linear equations A * X =
           B for GT matrices

Function/Subroutine Documentation

       CGTSVX computes the solution to system of linear equations A * X = B
      for GT matrices

Purpose:
   CGTSVX uses the LU factorization to compute the solution to a complex
   system of linear equations A * X = B, A**T * X = B, or A**H * X = B,
   where A is a tridiagonal matrix of order N and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:
   The following steps are performed:

   1. If FACT = 'N', the LU decomposition is used to factor the matrix A
      as A = L * U, where L is a product of permutation and unit lower
      bidiagonal matrices and U is upper triangular with nonzeros in
      only the main diagonal and first two superdiagonals.

   2. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  DLF, DF, DUF, DU2, and IPIV contain the factored form
           of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV will not
           be modified.
   = 'N':  The matrix will be copied to DLF, DF, and DUF and factored.

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)
```

```
N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

DL
  DL is COMPLEX array, dimension (N-1)
  The (n-1) subdiagonal elements of A.

D
  D is COMPLEX array, dimension (N)
  The n diagonal elements of A.

DU
  DU is COMPLEX array, dimension (N-1)
  The (n-1) superdiagonal elements of A.

DLF
  DLF is COMPLEX array, dimension (N-1)
  If FACT = 'F', then DLF is an input argument and on entry
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A as computed by CGTTRF.

  If FACT = 'N', then DLF is an output argument and on exit
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A.

DF
  DF is COMPLEX array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.

  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.

DUF
  DUF is COMPLEX array, dimension (N-1)
  If FACT = 'F', then DUF is an input argument and on entry
  contains the (n-1) elements of the first superdiagonal of U.

  If FACT = 'N', then DUF is an output argument and on exit
  contains the (n-1) elements of the first superdiagonal of U.

DU2
```

```
  DU2 is COMPLEX array, dimension (N-2)
  If FACT = 'F', then DU2 is an input argument and on entry
  contains the (n-2) elements of the second superdiagonal of U.

  If FACT = 'N', then DU2 is an output argument and on exit
  contains the (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the LU factorization of A as
  computed by CGTTRF.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the LU factorization of A;
  row i of the matrix was interchanged with row IPIV(i).
  IPIV(i) will always be either i or i+1; IPIV(i) = i indicates
  a row interchange was not required.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
```

```
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
     <= N:  U(i,i) is exactly zero.  The factorization
            has not been completed unless i = N, but the
            factor U is exactly singular, so the solution
            and error bounds could not be computed.
            RCOND = 0 is returned.
     = N+1: U is nonsingular, but RCOND is less than machine
            precision, meaning that the matrix is singular
            to working precision.  Nevertheless, the
            solution and error bounds are computed because
            there are a number of situations where the
            computed solution can be more accurate than the
            value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine zgtsv (N, NRHS, DL, D, DU, B, LDB, INFO)
            ZGTSV computes the solution to system of linear equations A * X =
           B for GT matrices

Function/Subroutine Documentation
   subroutine zgtsv (integer N, integer NRHS, complex*16, dimension( * ) DL,
       complex*16, dimension( * ) D, complex*16, dimension( * ) DU,
       complex*16, dimension( ldb, * ) B, integer LDB, integer INFO)
        ZGTSV computes the solution to system of linear equations A * X = B
       for GT matrices

Purpose:
   ZGTSV  solves the equation

   A*X = B,

   where A is an N-by-N tridiagonal matrix, by Gaussian elimination with
   partial pivoting.

   Note that the equation  A**T *X = B  may be solved by interchanging the
   order of the arguments DU and DL.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX*16 array, dimension (N-1)
   On entry, DL must contain the (n-1) subdiagonal elements of A.
   On exit, DL is overwritten by the (n-2) elements of the
   second superdiagonal of the upper triangular matrix U from
   the LU factorization of A, in DL(1), ..., DL(n-2).

 D
```

```
  D is COMPLEX*16 array, dimension (N)
  On entry, D must contain the diagonal elements of A.
  On exit, D is overwritten by the n diagonal elements of U.

DU
  DU is COMPLEX*16 array, dimension (N-1)
  On entry, DU must contain the (n-1) superdiagonal elements of A.
  On exit, DU is overwritten by the (n-1) elements of the first
  superdiagonal of U.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, U(i,i) is exactly zero, and the solution
        has not been computed.  The factorization has not been
        completed unless i = N.
```

      INFO)
       ZGTSVX computes the solution to system of linear equations A * X = B
      for GT matrices

Purpose:
   ZGTSVX uses the LU factorization to compute the solution to a complex
   system of linear equations A * X = B, A**T * X = B, or A**H * X = B,
   where A is a tridiagonal matrix of order N and X and B are N-by-NRHS
   matrices.

   Error bounds on the solution and a condition estimate are also
   provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the LU decomposition is used to factor the matrix A
      as A = L * U, where L is a product of permutation and unit lower
      bidiagonal matrices and U is upper triangular with nonzeros in
      only the main diagonal and first two superdiagonals.

   2. If some U(i,i)=0, so that U is exactly singular, then the routine
      returns with INFO = i. Otherwise, the factored form of A is used
      to estimate the condition number of the matrix A.  If the
      reciprocal of the condition number is less than machine precision,
      INFO = N+1 is returned as a warning, but the routine still goes on
      to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  DLF, DF, DUF, DU2, and IPIV contain the factored form
      of A; DL, D, DU, DLF, DF, DUF, DU2 and IPIV will not
      be modified.
   = 'N':  The matrix will be copied to DLF, DF, and DUF
      and factored.
```

```
TRANS
  TRANS is CHARACTER*1
  Specifies the form of the system of equations:
  = 'N':  A * X = B     (No transpose)
  = 'T':  A**T * X = B  (Transpose)
  = 'C':  A**H * X = B  (Conjugate transpose)

N
  N is INTEGER
  The order of the matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

DL
  DL is COMPLEX*16 array, dimension (N-1)
  The (n-1) subdiagonal elements of A.

D
  D is COMPLEX*16 array, dimension (N)
  The n diagonal elements of A.

DU
  DU is COMPLEX*16 array, dimension (N-1)
  The (n-1) superdiagonal elements of A.

DLF
  DLF is COMPLEX*16 array, dimension (N-1)
  If FACT = 'F', then DLF is an input argument and on entry
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A as computed by ZGTTRF.

  If FACT = 'N', then DLF is an output argument and on exit
  contains the (n-1) multipliers that define the matrix L from
  the LU factorization of A.

DF
  DF is COMPLEX*16 array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.

  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the upper triangular
  matrix U from the LU factorization of A.

DUF
```

```
  DUF is COMPLEX*16 array, dimension (N-1)
  If FACT = 'F', then DUF is an input argument and on entry
  contains the (n-1) elements of the first superdiagonal of U.

  If FACT = 'N', then DUF is an output argument and on exit
  contains the (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is COMPLEX*16 array, dimension (N-2)
  If FACT = 'F', then DU2 is an input argument and on entry
  contains the (n-2) elements of the second superdiagonal of U.

  If FACT = 'N', then DU2 is an output argument and on exit
  contains the (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  If FACT = 'F', then IPIV is an input argument and on entry
  contains the pivot indices from the LU factorization of A as
  computed by ZGTTRF.

  If FACT = 'N', then IPIV is an output argument and on exit
  contains the pivot indices from the LU factorization of A;
  row i of the matrix was interchanged with row IPIV(i).
  IPIV(i) will always be either i or i+1; IPIV(i) = i indicates
  a row interchange was not required.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The estimate of the reciprocal condition number of the matrix
  A.  If RCOND is less than the machine precision (in
  particular, if RCOND = 0), the matrix is singular to working
  precision.  This condition is indicated by a return code of INFO > 0.
```

```
FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  U(i,i) is exactly zero.  The factorization
     has not been completed unless i = N, but the
     factor U is exactly singular, so the solution
     and error bounds could not be computed.
     RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine dgtcon (NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK,
           IWORK, INFO)
           DGTCON

Function/Subroutine Documentation
   subroutine dgtcon (character NORM, integer N, double precision, dimension(
       * ) DL, double precision, dimension( * ) D, double precision,
       dimension( * ) DU, double precision, dimension( * ) DU2, integer,
       dimension( * ) IPIV, double precision ANORM, double precision RCOND,
       double precision, dimension( * ) WORK, integer, dimension( * ) IWORK,
       integer INFO)
       DGTCON

Purpose:
   DGTCON estimates the reciprocal of the condition number of a real
   tridiagonal matrix A using the LU factorization as computed by
   DGTTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 DL
   DL is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by DGTTRF.

 D
   D is DOUBLE PRECISION array, dimension (N)
```

```
  The n diagonal elements of the upper triangular matrix U from
  the LU factorization of A.

DU
  DU is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is DOUBLE PRECISION array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM
  ANORM is DOUBLE PRECISION
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgtrfs (TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, IWORK, INFO)
           DGTRFS

Function/Subroutine Documentation
   subroutine dgtrfs (character TRANS, integer N, integer NRHS, double
       precision, dimension( * ) DL, double precision, dimension( * ) D,
       double precision, dimension( * ) DU, double precision, dimension( * )
       DLF, double precision, dimension( * ) DF, double precision, dimension(
       * ) DUF, double precision, dimension( * ) DU2, integer, dimension( * )
       IPIV, double precision, dimension( ldb, * ) B, integer LDB, double
       precision, dimension( ldx, * ) X, integer LDX, double precision,
       dimension( * ) FERR, double precision, dimension( * ) BERR, double
       precision, dimension( * ) WORK, integer, dimension( * ) IWORK, integer
```

```
       INFO)
       DGTRFS

Purpose:
   DGTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is tridiagonal, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) subdiagonal elements of A.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The diagonal elements of A.

 DU
   DU is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) superdiagonal elements of A.

 DLF
   DLF is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by DGTTRF.

 DF
   DF is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DUF
   DUF is DOUBLE PRECISION array, dimension (N-1)
```

```
  The (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is DOUBLE PRECISION array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by DGTTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is DOUBLE PRECISION array, dimension (3*N)

IWORK
```

```
   IWORK is INTEGER array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgttrf (N, DL, D, DU, DU2, IPIV, INFO)
           DGTTRF

Function/Subroutine Documentation
   subroutine dgttrf (integer N, double precision, dimension( * ) DL, double
       precision, dimension( * ) D, double precision, dimension( * ) DU,
       double precision, dimension( * ) DU2, integer, dimension( * ) IPIV,
       integer INFO)
       DGTTRF

Purpose:
   DGTTRF computes an LU factorization of a real tridiagonal matrix A
   using elimination with partial pivoting and row interchanges.

   The factorization has the form
      A = L * U
   where L is a product of permutation and unit lower bidiagonal
   matrices and U is upper triangular with nonzeros in only the main
   diagonal and first two superdiagonals.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.

 DL
   DL is DOUBLE PRECISION array, dimension (N-1)
   On entry, DL must contain the (n-1) sub-diagonal elements of A.

   On exit, DL is overwritten by the (n-1) multipliers that
   define the matrix L from the LU factorization of A.
```

```
D
  D is DOUBLE PRECISION array, dimension (N)
  On entry, D must contain the diagonal elements of A.

  On exit, D is overwritten by the n diagonal elements of the
  upper triangular matrix U from the LU factorization of A.

DU
  DU is DOUBLE PRECISION array, dimension (N-1)
  On entry, DU must contain the (n-1) super-diagonal elements of A.

  On exit, DU is overwritten by the (n-1) elements of the first
  super-diagonal of U.

DU2
  DU2 is DOUBLE PRECISION array, dimension (N-2)
  On exit, DU2 is overwritten by the (n-2) elements of the
  second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -k, the k-th argument had an illegal value
  > 0:  if INFO = k, U(k,k) is exactly zero. The factorization
        has been completed, but the factor U is exactly
        singular, and division by zero will occur if it is used
        to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgttrs (TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
           DGTTRS

Function/Subroutine Documentation
   subroutine dgttrs (character TRANS, integer N, integer NRHS, double
       precision, dimension( * ) DL, double precision, dimension( * ) D,
       double precision, dimension( * ) DU, double precision, dimension( * )
       DU2, integer, dimension( * ) IPIV, double precision, dimension( ldb, *
       ) B, integer LDB, integer INFO)
       DGTTRS

Purpose:
   DGTTRS solves one of the systems of equations
      A*X = B  or  A**T*X = B,
   with a tridiagonal matrix A using the LU factorization computed
   by DGTTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B  (No transpose)
   = 'T':  A**T* X = B  (Transpose)
   = 'C':  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
   D is DOUBLE PRECISION array, dimension (N)
```

```
  The n diagonal elements of the upper triangular matrix U from
  the LU factorization of A.

DU
  DU is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) elements of the first super-diagonal of U.

DU2
  DU2 is DOUBLE PRECISION array, dimension (N-2)
  The (n-2) elements of the second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the matrix of right hand side vectors B.
  On exit, B is overwritten by the solution vectors X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dgtts2 (ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
           DGTTS2 solves a system of linear equations with a tridiagonal
           matrix using the LU factorization computed by sgttrf.

Function/Subroutine Documentation
   subroutine dgtts2 (integer ITRANS, integer N, integer NRHS, double
       precision, dimension( * ) DL, double precision, dimension( * ) D,
       double precision, dimension( * ) DU, double precision, dimension( * )
       DU2, integer, dimension( * ) IPIV, double precision, dimension( ldb, *
       ) B, integer LDB)
       DGTTS2 solves a system of linear equations with a tridiagonal matrix
       using the LU factorization computed by sgttrf.

Purpose:
```

```
  DGTTS2 solves one of the systems of equations
     A*X = B  or  A**T*X = B,
  with a tridiagonal matrix A using the LU factorization computed by DGTTRF.

Parameters:

 ITRANS
   ITRANS is INTEGER
   Specifies the form of the system of equations.
   = 0:  A * X = B  (No transpose)
   = 1:  A**T* X = B  (Transpose)
   = 2:  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DU
   DU is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) elements of the first super-diagonal of U.

 DU2
   DU2 is DOUBLE PRECISION array, dimension (N-2)
   The (n-2) elements of the second super-diagonal of U.

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices; for 1 <= i <= n, row i of the matrix was
   interchanged with row IPIV(i).  IPIV(i) will always be either
   i or i+1; IPIV(i) = i indicates a row interchange was not required.

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the matrix of right hand side vectors B.
   On exit, B is overwritten by the solution vectors X.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgtcon (NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK,
           IWORK, INFO)
           SGTCON

Function/Subroutine Documentation
   subroutine sgtcon (character NORM, integer N, real, dimension( * ) DL,
       real, dimension( * ) D, real, dimension( * ) DU, real, dimension( * )
       DU2, integer, dimension( * ) IPIV, real ANORM, real RCOND, real,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SGTCON

Purpose:
   SGTCON estimates the reciprocal of the condition number of a real
   tridiagonal matrix A using the LU factorization as computed by
   SGTTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 DL
   DL is REAL array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by SGTTRF.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DU
```

```
  DU is REAL array, dimension (N-1)
  The (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is REAL array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM
  ANORM is REAL
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is REAL
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is REAL array, dimension (2*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgtrfs (TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, IWORK, INFO)
           SGTRFS

Function/Subroutine Documentation
   subroutine sgtrfs (character TRANS, integer N, integer NRHS, real,
       dimension( * ) DL, real, dimension( * ) D, real, dimension( * ) DU,
       real, dimension( * ) DLF, real, dimension( * ) DF, real, dimension( * )
       DUF, real, dimension( * ) DU2, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, real, dimension( ldx, * ) X,
       integer LDX, real, dimension( * ) FERR, real, dimension( * ) BERR,
       real, dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SGTRFS
```

```
Purpose:
   SGTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is tridiagonal, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is REAL array, dimension (N-1)
   The (n-1) subdiagonal elements of A.

 D
   D is REAL array, dimension (N)
   The diagonal elements of A.

 DU
   DU is REAL array, dimension (N-1)
   The (n-1) superdiagonal elements of A.

 DLF
   DLF is REAL array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by SGTTRF.

 DF
   DF is REAL array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DUF
   DUF is REAL array, dimension (N-1)
   The (n-1) elements of the first superdiagonal of U.

 DU2
```

```
  DU2 is REAL array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is REAL array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by SGTTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (3*N)

IWORK
  IWORK is INTEGER array, dimension (N)

INFO
```

```
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.

SYNOPSIS
   Functions/Subroutines
       subroutine sgttrf (N, DL, D, DU, DU2, IPIV, INFO)
           SGTTRF

Function/Subroutine Documentation
   subroutine sgttrf (integer N, real, dimension( * ) DL, real, dimension( * )
       D, real, dimension( * ) DU, real, dimension( * ) DU2, integer,
       dimension( * ) IPIV, integer INFO)
       SGTTRF

Purpose:
   SGTTRF computes an LU factorization of a real tridiagonal matrix A
   using elimination with partial pivoting and row interchanges.

   The factorization has the form
      A = L * U
   where L is a product of permutation and unit lower bidiagonal
   matrices and U is upper triangular with nonzeros in only the main
   diagonal and first two superdiagonals.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.

 DL
   DL is REAL array, dimension (N-1)
   On entry, DL must contain the (n-1) sub-diagonal elements of A.

   On exit, DL is overwritten by the (n-1) multipliers that
   define the matrix L from the LU factorization of A.

 D
   D is REAL array, dimension (N)
   On entry, D must contain the diagonal elements of A.
```

```
  On exit, D is overwritten by the n diagonal elements of the
  upper triangular matrix U from the LU factorization of A.

DU
  DU is REAL array, dimension (N-1)
  On entry, DU must contain the (n-1) super-diagonal elements of A.

  On exit, DU is overwritten by the (n-1) elements of the first
  super-diagonal of U.

DU2
  DU2 is REAL array, dimension (N-2)
  On exit, DU2 is overwritten by the (n-2) elements of the
  second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -k, the k-th argument had an illegal value
  > 0:  if INFO = k, U(k,k) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine sgttrs (TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
           SGTTRS

Function/Subroutine Documentation
   subroutine sgttrs (character TRANS, integer N, integer NRHS, real,
       dimension( * ) DL, real, dimension( * ) D, real, dimension( * ) DU,
       real, dimension( * ) DU2, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       SGTTRS

Purpose:
   SGTTRS solves one of the systems of equations
      A*X = B  or  A**T*X = B,
   with a tridiagonal matrix A using the LU factorization computed by SGTTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B  (No transpose)
   = 'T':  A**T* X = B  (Transpose)
   = 'C':  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is REAL array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DU
   DU is REAL array, dimension (N-1)
   The (n-1) elements of the first super-diagonal of U.
```

```
 DU2
   DU2 is REAL array, dimension (N-2)
   The (n-2) elements of the second super-diagonal of U.

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices; for 1 <= i <= n, row i of the matrix was
   interchanged with row IPIV(i).  IPIV(i) will always be either
   i or i+1; IPIV(i) = i indicates a row interchange was not required.

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the matrix of right hand side vectors B.
   On exit, B is overwritten by the solution vectors X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine sgtts2 (ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
           SGTTS2 solves a system of linear equations with a tridiagonal
           matrix using the LU factorization computed by sgttrf.

Function/Subroutine Documentation
   subroutine sgtts2 (integer ITRANS, integer N, integer NRHS, real,
       dimension( * ) DL, real, dimension( * ) D, real, dimension( * ) DU,
       real, dimension( * ) DU2, integer, dimension( * ) IPIV, real,
       dimension( ldb, * ) B, integer LDB)
       SGTTS2 solves a system of linear equations with a tridiagonal matrix
       using the LU factorization computed by sgttrf.

Purpose:
   SGTTS2 solves one of the systems of equations
```

```
      A*X = B  or  A**T*X = B,
  with a tridiagonal matrix A using the LU factorization computed by SGTTRF.

Parameters:

 ITRANS
   ITRANS is INTEGER
   Specifies the form of the system of equations.
   = 0:  A * X = B  (No transpose)
   = 1:  A**T* X = B  (Transpose)
   = 2:  A**T* X = B  (Conjugate transpose = Transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is REAL array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DU
   DU is REAL array, dimension (N-1)
   The (n-1) elements of the first super-diagonal of U.

 DU2
   DU2 is REAL array, dimension (N-2)
   The (n-2) elements of the second super-diagonal of U.

 IPIV
   IPIV is INTEGER array, dimension (N)
   The pivot indices; for 1 <= i <= n, row i of the matrix was
   interchanged with row IPIV(i).  IPIV(i) will always be either
   i or i+1; IPIV(i) = i indicates a row interchange was not required.

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the matrix of right hand side vectors B.
   On exit, B is overwritten by the solution vectors X.
```

```
LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgtcon (NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK,
           INFO)
           CGTCON

Function/Subroutine Documentation
   subroutine cgtcon (character NORM, integer N, complex, dimension( * ) DL,
       complex, dimension( * ) D, complex, dimension( * ) DU, complex,
       dimension( * ) DU2, integer, dimension( * ) IPIV, real ANORM, real
       RCOND, complex, dimension( * ) WORK, integer INFO)
       CGTCON

Purpose:
   CGTCON estimates the reciprocal of the condition number of a complex
   tridiagonal matrix A using the LU factorization as computed by
   CGTTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 DL
   DL is COMPLEX array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by CGTTRF.

 D
   D is COMPLEX array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.
```

```
DU
  DU is COMPLEX array, dimension (N-1)
  The (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is COMPLEX array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM
  ANORM is REAL
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is REAL
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is COMPLEX array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgtrfs (TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, RWORK, INFO)
           CGTRFS

Function/Subroutine Documentation
   subroutine cgtrfs (character TRANS, integer N, integer NRHS, complex,
       dimension( * ) DL, complex, dimension( * ) D, complex, dimension( * )
       DU, complex, dimension( * ) DLF, complex, dimension( * ) DF, complex,
       dimension( * ) DUF, complex, dimension( * ) DU2, integer, dimension( *
       ) IPIV, complex, dimension( ldb, * ) B, integer LDB, complex,
       dimension( ldx, * ) X, integer LDX, real, dimension( * ) FERR, real,
       dimension( * ) BERR, complex, dimension( * ) WORK, real, dimension( * )
       RWORK, integer INFO)
       CGTRFS
```

```
Purpose:
   CGTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is tridiagonal, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX array, dimension (N-1)
   The (n-1) subdiagonal elements of A.

 D
   D is COMPLEX array, dimension (N)
   The diagonal elements of A.

 DU
   DU is COMPLEX array, dimension (N-1)
   The (n-1) superdiagonal elements of A.

 DLF
   DLF is COMPLEX array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by CGTTRF.

 DF
   DF is COMPLEX array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DUF
   DUF is COMPLEX array, dimension (N-1)
   The (n-1) elements of the first superdiagonal of U.
```

```
DU2
  DU2 is COMPLEX array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CGTTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (2*N)

RWORK
  RWORK is REAL array, dimension (N)
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

 ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgttrf (N, DL, D, DU, DU2, IPIV, INFO)
           CGTTRF

Function/Subroutine Documentation
   subroutine cgttrf (integer N, complex, dimension( * ) DL, complex,
       dimension( * ) D, complex, dimension( * ) DU, complex, dimension( * )
       DU2, integer, dimension( * ) IPIV, integer INFO)
       CGTTRF

Purpose:
   CGTTRF computes an LU factorization of a complex tridiagonal matrix A
   using elimination with partial pivoting and row interchanges.

   The factorization has the form
     A = L * U
   where L is a product of permutation and unit lower bidiagonal
   matrices and U is upper triangular with nonzeros in only the main
   diagonal and first two superdiagonals.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.

 DL
   DL is COMPLEX array, dimension (N-1)
   On entry, DL must contain the (n-1) sub-diagonal elements of A.

   On exit, DL is overwritten by the (n-1) multipliers that
   define the matrix L from the LU factorization of A.

 D
   D is COMPLEX array, dimension (N)
   On entry, D must contain the diagonal elements of A.

   On exit, D is overwritten by the n diagonal elements of the
   upper triangular matrix U from the LU factorization of A.

 DU
   DU is COMPLEX array, dimension (N-1)
   On entry, DU must contain the (n-1) super-diagonal elements of A.
```

```
  On exit, DU is overwritten by the (n-1) elements of the first
  super-diagonal of U.

DU2
  DU2 is COMPLEX array, dimension (N-2)
  On exit, DU2 is overwritten by the (n-2) elements of the
  second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -k, the k-th argument had an illegal value
  > 0:  if INFO = k, U(k,k) is exactly zero. The factorization
        has been completed, but the factor U is exactly
        singular, and division by zero will occur if it is used
        to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgttrs (TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
           CGTTRS

Function/Subroutine Documentation
   subroutine cgttrs (character TRANS, integer N, integer NRHS, complex,
       dimension( * ) DL, complex, dimension( * ) D, complex, dimension( * )
       DU, complex, dimension( * ) DU2, integer, dimension( * ) IPIV, complex,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       CGTTRS

Purpose:
   CGTTRS solves one of the systems of equations
      A * X = B,  A**T * X = B,  or  A**H * X = B,
   with a tridiagonal matrix A using the LU factorization computed
   by CGTTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
```

```
  D is COMPLEX array, dimension (N)
  The n diagonal elements of the upper triangular matrix U from
  the LU factorization of A.

DU
  DU is COMPLEX array, dimension (N-1)
  The (n-1) elements of the first super-diagonal of U.

DU2
  DU2 is COMPLEX array, dimension (N-2)
  The (n-2) elements of the second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the matrix of right hand side vectors B.
  On exit, B is overwritten by the solution vectors X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -k, the k-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine cgtts2 (ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
          CGTTS2 solves a system of linear equations with a tridiagonal
          matrix using the LU factorization computed by sgttrf.

Function/Subroutine Documentation
   subroutine cgtts2 (integer ITRANS, integer N, integer NRHS, complex,
       dimension( * ) DL, complex, dimension( * ) D, complex, dimension( * )
       DU, complex, dimension( * ) DU2, integer, dimension( * ) IPIV, complex,
       dimension( ldb, * ) B, integer LDB)
       CGTTS2 solves a system of linear equations with a tridiagonal matrix
       using the LU factorization computed by sgttrf.

Purpose:
   CGTTS2 solves one of the systems of equations
      A * X = B,  A**T * X = B,  or  A**H * X = B,
   with a tridiagonal matrix A using the LU factorization computed
   by CGTTRF.

Parameters:

 ITRANS
   ITRANS is INTEGER
   Specifies the form of the system of equations.
   = 0:  A * X = B     (No transpose)
   = 1:  A**T * X = B  (Transpose)
   = 2:  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
   D is COMPLEX array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DU
   DU is COMPLEX array, dimension (N-1)
   The (n-1) elements of the first super-diagonal of U.
```

```
DU2
  DU2 is COMPLEX array, dimension (N-2)
  The (n-2) elements of the second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the matrix of right hand side vectors B.
  On exit, B is overwritten by the solution vectors X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgtcon (NORM, N, DL, D, DU, DU2, IPIV, ANORM, RCOND, WORK,
           INFO)
           ZGTCON

Function/Subroutine Documentation
   subroutine zgtcon (character NORM, integer N, complex*16, dimension( * )
       DL, complex*16, dimension( * ) D, complex*16, dimension( * ) DU,
       complex*16, dimension( * ) DU2, integer, dimension( * ) IPIV, double
       precision ANORM, double precision RCOND, complex*16, dimension( * )
       WORK, integer INFO)
       ZGTCON

Purpose:
   ZGTCON estimates the reciprocal of the condition number of a complex
   tridiagonal matrix A using the LU factorization as computed by ZGTTRF.

   An estimate is obtained for norm(inv(A)), and the reciprocal of the
   condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies whether the 1-norm condition number or the
   infinity-norm condition number is required:
   = '1' or 'O':  1-norm;
   = 'I':         Infinity-norm.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 DL
   DL is COMPLEX*16 array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by ZGTTRF.

 D
   D is COMPLEX*16 array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.
```

```
DU
  DU is COMPLEX*16 array, dimension (N-1)
  The (n-1) elements of the first superdiagonal of U.

DU2
  DU2 is COMPLEX*16 array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

ANORM
  ANORM is DOUBLE PRECISION
  If NORM = '1' or 'O', the 1-norm of the original matrix A.
  If NORM = 'I', the infinity-norm of the original matrix A.

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an
  estimate of the 1-norm of inv(A) computed in this routine.

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgtrfs (TRANS, N, NRHS, DL, D, DU, DLF, DF, DUF, DU2, IPIV,
           B, LDB, X, LDX, FERR, BERR, WORK, RWORK, INFO)
           ZGTRFS

Function/Subroutine Documentation
   subroutine zgtrfs (character TRANS, integer N, integer NRHS, complex*16,
       dimension( * ) DL, complex*16, dimension( * ) D, complex*16, dimension(
       * ) DU, complex*16, dimension( * ) DLF, complex*16, dimension( * ) DF,
       complex*16, dimension( * ) DUF, complex*16, dimension( * ) DU2,
       integer, dimension( * ) IPIV, complex*16, dimension( ldb, * ) B,
       integer LDB, complex*16, dimension( ldx, * ) X, integer LDX, double
       precision, dimension( * ) FERR, double precision, dimension( * ) BERR,
       complex*16, dimension( * ) WORK, double precision, dimension( * )
       RWORK, integer INFO)
```

```
       ZGTRFS

Purpose:
   ZGTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is tridiagonal, and provides
   error bounds and backward error estimates for the solution.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations:
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX*16 array, dimension (N-1)
   The (n-1) subdiagonal elements of A.

 D
   D is COMPLEX*16 array, dimension (N)
   The diagonal elements of A.

 DU
   DU is COMPLEX*16 array, dimension (N-1)
   The (n-1) superdiagonal elements of A.

 DLF
   DLF is COMPLEX*16 array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A as computed by ZGTTRF.

 DF
   DF is COMPLEX*16 array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.

 DUF
   DUF is COMPLEX*16 array, dimension (N-1)
   The (n-1) elements of the first superdiagonal of U.
```

```
DU2
  DU2 is COMPLEX*16 array, dimension (N-2)
  The (n-2) elements of the second superdiagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZGTTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The estimated forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).  The estimate is as reliable as
  the estimate for RCOND, and is almost always a slight
  overestimate of the true error.

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (2*N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)
```

```
 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgttrf (N, DL, D, DU, DU2, IPIV, INFO)
           ZGTTRF

Function/Subroutine Documentation
   subroutine zgttrf (integer N, complex*16, dimension( * ) DL, complex*16,
       dimension( * ) D, complex*16, dimension( * ) DU, complex*16, dimension(
       * ) DU2, integer, dimension( * ) IPIV, integer INFO)
       ZGTTRF

Purpose:
   ZGTTRF computes an LU factorization of a complex tridiagonal matrix A
   using elimination with partial pivoting and row interchanges.

   The factorization has the form
      A = L * U
   where L is a product of permutation and unit lower bidiagonal
   matrices and U is upper triangular with nonzeros in only the main
   diagonal and first two superdiagonals.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.

 DL
   DL is COMPLEX*16 array, dimension (N-1)
   On entry, DL must contain the (n-1) sub-diagonal elements of A.

   On exit, DL is overwritten by the (n-1) multipliers that
   define the matrix L from the LU factorization of A.

 D
   D is COMPLEX*16 array, dimension (N)
   On entry, D must contain the diagonal elements of A.

   On exit, D is overwritten by the n diagonal elements of the
   upper triangular matrix U from the LU factorization of A.

 DU
```

```
  DU is COMPLEX*16 array, dimension (N-1)
  On entry, DU must contain the (n-1) super-diagonal elements of A.

  On exit, DU is overwritten by the (n-1) elements of the first
  super-diagonal of U.

DU2
  DU2 is COMPLEX*16 array, dimension (N-2)
  On exit, DU2 is overwritten by the (n-2) elements of the
  second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not
  required.

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -k, the k-th argument had an illegal value
  > 0:  if INFO = k, U(k,k) is exactly zero. The factorization
     has been completed, but the factor U is exactly
     singular, and division by zero will occur if it is used
     to solve a system of equations.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgttrs (TRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB, INFO)
           ZGTTRS

Function/Subroutine Documentation
   subroutine zgttrs (character TRANS, integer N, integer NRHS, complex*16,
       dimension( * ) DL, complex*16, dimension( * ) D, complex*16, dimension(
       * ) DU, complex*16, dimension( * ) DU2, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB, integer INFO)
       ZGTTRS

Purpose:
   ZGTTRS solves one of the systems of equations
      A * X = B,  A**T * X = B,  or  A**H * X = B,
   with a tridiagonal matrix A using the LU factorization computed by ZGTTRF.

Parameters:

 TRANS
   TRANS is CHARACTER*1
   Specifies the form of the system of equations.
   = 'N':  A * X = B     (No transpose)
   = 'T':  A**T * X = B  (Transpose)
   = 'C':  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX*16 array, dimension (N-1)
```

```
  The (n-1) multipliers that define the matrix L from the
  LU factorization of A.

D
  D is COMPLEX*16 array, dimension (N)
  The n diagonal elements of the upper triangular matrix U from
  the LU factorization of A.

DU
  DU is COMPLEX*16 array, dimension (N-1)
  The (n-1) elements of the first super-diagonal of U.

DU2
  DU2 is COMPLEX*16 array, dimension (N-2)
  The (n-2) elements of the second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the matrix of right hand side vectors B.
  On exit, B is overwritten by the solution vectors X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -k, the k-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zgtts2 (ITRANS, N, NRHS, DL, D, DU, DU2, IPIV, B, LDB)
           ZGTTS2 solves a system of linear equations with a tridiagonal
           matrix using the LU factorization computed by sgttrf.

Function/Subroutine Documentation
   subroutine zgtts2 (integer ITRANS, integer N, integer NRHS, complex*16,
       dimension( * ) DL, complex*16, dimension( * ) D, complex*16, dimension(
       * ) DU, complex*16, dimension( * ) DU2, integer, dimension( * ) IPIV,
       complex*16, dimension( ldb, * ) B, integer LDB)
       ZGTTS2 solves a system of linear equations with a tridiagonal matrix
       using the LU factorization computed by sgttrf.

Purpose:
   ZGTTS2 solves one of the systems of equations
      A * X = B,  A**T * X = B,  or  A**H * X = B,
   with a tridiagonal matrix A using the LU factorization computed by ZGTTRF.

Parameters:

 ITRANS
   ITRANS is INTEGER
   Specifies the form of the system of equations.
   = 0:  A * X = B     (No transpose)
   = 1:  A**T * X = B  (Transpose)
   = 2:  A**H * X = B  (Conjugate transpose)

 N
   N is INTEGER
   The order of the matrix A.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 DL
   DL is COMPLEX*16 array, dimension (N-1)
   The (n-1) multipliers that define the matrix L from the
   LU factorization of A.

 D
   D is COMPLEX*16 array, dimension (N)
   The n diagonal elements of the upper triangular matrix U from
   the LU factorization of A.
```

```
DU
  DU is COMPLEX*16 array, dimension (N-1)
  The (n-1) elements of the first super-diagonal of U.

DU2
  DU2 is COMPLEX*16 array, dimension (N-2)
  The (n-2) elements of the second super-diagonal of U.

IPIV
  IPIV is INTEGER array, dimension (N)
  The pivot indices; for 1 <= i <= n, row i of the matrix was
  interchanged with row IPIV(i).  IPIV(i) will always be either
  i or i+1; IPIV(i) = i indicates a row interchange was not required.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the matrix of right hand side vectors B.
  On exit, B is overwritten by the solution vectors X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

SYNOPSIS
   Functions/Subroutines
       subroutine dptsv (N, NRHS, D, E, B, LDB, INFO)
            DPTSV computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine dptsv (integer N, integer NRHS, double precision, dimension( * )
       D, double precision, dimension( * ) E, double precision, dimension(
       ldb, * ) B, integer LDB, integer INFO)
        DPTSV computes the solution to system of linear equations A * X = B
       for PT matrices

Purpose:
   DPTSV computes the solution to a real system of linear equations
   A*X = B, where A is an N-by-N symmetric positive definite tridiagonal
   matrix, and X and B are N-by-NRHS matrices.

   A is factored as A = L*D*L**T, and the factored form of A is then
   used to solve the system of equations.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the factorization A = L*D*L**T.

 E
   E is DOUBLE PRECISION array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**T factorization of
```

```
  A.  (E can also be regarded as the superdiagonal of the unit
  bidiagonal factor U from the U**T*D*U factorization of A.)

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
        positive definite, and the solution has not been
        computed.  The factorization has not been completed unless i = N.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dptsvx (FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND,
           FERR, BERR, WORK, INFO)
            DPTSVX computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine dptsvx (character FACT, integer N, integer NRHS, double
       precision, dimension( * ) D, double precision, dimension( * ) E, double
       precision, dimension( * ) DF, double precision, dimension( * ) EF,
       double precision, dimension( ldb, * ) B, integer LDB, double precision,
       dimension( ldx, * ) X, integer LDX, double precision RCOND, double
       precision, dimension( * ) FERR, double precision, dimension( * ) BERR,
       double precision, dimension( * ) WORK, integer INFO)
        DPTSVX computes the solution to system of linear equations A * X = B
```

```
      for PT matrices

Purpose:
   DPTSVX uses the factorization A = L*D*L**T to compute the solution
   to a real system of linear equations A*X = B, where A is an N-by-N
   symmetric positive definite tridiagonal matrix and X and B are
   N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the matrix A is factored as A = L*D*L**T, where L
      is a unit lower bidiagonal matrix and D is diagonal.  The
      factorization can also be regarded as having the form
      A = U**T*D*U.

   2. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  On entry, DF and EF contain the factored form of A.
      D, E, DF, and EF will not be modified.
   = 'N':  The matrix A will be copied to DF and EF and factored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.
```

```
D
  D is DOUBLE PRECISION array, dimension (N)
  The n diagonal elements of the tridiagonal matrix A.

E
  E is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF
  DF is DOUBLE PRECISION array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**T factorization of A.
  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**T factorization of A.

EF
  EF is DOUBLE PRECISION array, dimension (N-1)
  If FACT = 'F', then EF is an input argument and on entry
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**T factorization of A.
  If FACT = 'N', then EF is an output argument and on exit
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**T factorization of A.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is DOUBLE PRECISION array, dimension (LDX,NRHS)
  If INFO = 0 of INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
  The reciprocal condition number of the matrix A.  If RCOND
  is less than the machine precision (in particular, if
  RCOND = 0), the matrix is singular to working precision.
  This condition is indicated by a return code of INFO > 0.
```

```
 FERR
   FERR is DOUBLE PRECISION array, dimension (NRHS)
   The forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in any
   element of A or B that makes X(j) an exact solution).

 WORK
   WORK is DOUBLE PRECISION array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
   > 0:  if INFO = i, and i is
   <= N:  the leading minor of order i of A is
      not positive definite, so the factorization
      could not be completed, and the solution has not
      been computed. RCOND = 0 is returned.
   = N+1: U is nonsingular, but RCOND is less than machine
      precision, meaning that the matrix is singular
      to working precision.  Nevertheless, the
      solution and error bounds are computed because
      there are a number of situations where the
      computed solution can be more accurate than the
      value of RCOND would suggest.
