SYNOPSIS
   Functions/Subroutines
       subroutine sptsv (N, NRHS, D, E, B, LDB, INFO)
            SPTSV computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine sptsv (integer N, integer NRHS, real, dimension( * ) D, real,
       dimension( * ) E, real, dimension( ldb, * ) B, integer LDB, integer
       INFO)
        SPTSV computes the solution to system of linear equations A * X = B
       for PT matrices

Purpose:
   SPTSV computes the solution to a real system of linear equations
   A*X = B, where A is an N-by-N symmetric positive definite tridiagonal
   matrix, and X and B are N-by-NRHS matrices.

   A is factored as A = L*D*L**T, and the factored form of A is then
   used to solve the system of equations.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is REAL array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the factorization A = L*D*L**T.

 E
   E is REAL array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**T factorization of
```

```
  A.  (E can also be regarded as the superdiagonal of the unit
  bidiagonal factor U from the U**T*D*U factorization of A.)

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
        positive definite, and the solution has not been
        computed.  The factorization has not been completed unless i = N.
```

SYNOPSIS
   Functions/Subroutines
       subroutine sptsvx (FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND,
           FERR, BERR, WORK, INFO)
            SPTSVX computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine sptsvx (character FACT, integer N, integer NRHS, real,
       dimension( * ) D, real, dimension( * ) E, real, dimension( * ) DF,
       real, dimension( * ) EF, real, dimension( ldb, * ) B, integer LDB,
       real, dimension( ldx, * ) X, integer LDX, real RCOND, real, dimension(
       * ) FERR, real, dimension( * ) BERR, real, dimension( * ) WORK, integer
       INFO)
        SPTSVX computes the solution to system of linear equations A * X = B
       for PT matrices
```

```
Purpose:
   SPTSVX uses the factorization A = L*D*L**T to compute the solution
   to a real system of linear equations A*X = B, where A is an N-by-N
   symmetric positive definite tridiagonal matrix and X and B are
   N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the matrix A is factored as A = L*D*L**T, where L
      is a unit lower bidiagonal matrix and D is diagonal.  The
      factorization can also be regarded as having the form
      A = U**T*D*U.

   2. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of A has been
   supplied on entry.
   = 'F':  On entry, DF and EF contain the factored form of A.
           D, E, DF, and EF will not be modified.
   = 'N':  The matrix A will be copied to DF and EF and factored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrices B and X.  NRHS >= 0.

 D
```

```
  D is REAL array, dimension (N)
  The n diagonal elements of the tridiagonal matrix A.

E
  E is REAL array, dimension (N-1)
  The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF
  DF is REAL array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**T factorization of A.
  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**T factorization of A.

EF
  EF is REAL array, dimension (N-1)
  If FACT = 'F', then EF is an input argument and on entry
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**T factorization of A.
  If FACT = 'N', then EF is an output argument and on exit
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**T factorization of A.

B
  B is REAL array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is REAL array, dimension (LDX,NRHS)
  If INFO = 0 of INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The reciprocal condition number of the matrix A.  If RCOND
  is less than the machine precision (in particular, if
  RCOND = 0), the matrix is singular to working precision.
  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
```

```
  The forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in any
  element of A or B that makes X(j) an exact solution).

WORK
  WORK is REAL array, dimension (2*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  the leading minor of order i of A is
     not positive definite, so the factorization
     could not be completed, and the solution has not
     been computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine cptsv (N, NRHS, D, E, B, LDB, INFO)
            CPTSV computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine cptsv (integer N, integer NRHS, real, dimension( * ) D, complex,
       dimension( * ) E, complex, dimension( ldb, * ) B, integer LDB, integer
       INFO)
        CPTSV computes the solution to system of linear equations A * X = B
       for PT matrices

Purpose:
   CPTSV computes the solution to a complex system of linear equations
   A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal
   matrix, and X and B are N-by-NRHS matrices.

   A is factored as A = L*D*L**H, and the factored form of A is then
   used to solve the system of equations.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is REAL array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the factorization A = L*D*L**H.

 E
   E is COMPLEX array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**H factorization of
```

```
  A.  E can also be regarded as the superdiagonal of the unit
  bidiagonal factor U from the U**H*D*U factorization of A.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
        positive definite, and the solution has not been
        computed.  The factorization has not been completed unless i = N.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cptsvx (FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND,
           FERR, BERR, WORK, RWORK, INFO)
            CPTSVX computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine cptsvx (character FACT, integer N, integer NRHS, real,
       dimension( * ) D, complex, dimension( * ) E, real, dimension( * ) DF,
       complex, dimension( * ) EF, complex, dimension( ldb, * ) B, integer
       LDB, complex, dimension( ldx, * ) X, integer LDX, real RCOND, real,
```

```
      dimension( * ) FERR, real, dimension( * ) BERR, complex, dimension( * )
      WORK, real, dimension( * ) RWORK, integer INFO)
       CPTSVX computes the solution to system of linear equations A * X = B
      for PT matrices

Purpose:
   CPTSVX uses the factorization A = L*D*L**H to compute the solution
   to a complex system of linear equations A*X = B, where A is an
   N-by-N Hermitian positive definite tridiagonal matrix and X and B
   are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also  provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the matrix A is factored as A = L*D*L**H, where L
      is a unit lower bidiagonal matrix and D is diagonal.  The
      factorization can also be regarded as having the form
      A = U**H*D*U.

   2. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix
   A is supplied on entry.
   = 'F':  On entry, DF and EF contain the factored form of A.
           D, E, DF, and EF will not be modified.
   = 'N':  The matrix A will be copied to DF and EF and factored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
```

```
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

D
  D is REAL array, dimension (N)
  The n diagonal elements of the tridiagonal matrix A.

E
  E is COMPLEX array, dimension (N-1)
  The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF
  DF is REAL array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**H factorization of A.
  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**H factorization of A.

EF
  EF is COMPLEX array, dimension (N-1)
  If FACT = 'F', then EF is an input argument and on entry
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**H factorization of A.
  If FACT = 'N', then EF is an output argument and on exit
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**H factorization of A.

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is REAL
  The reciprocal condition number of the matrix A.  If RCOND
  is less than the machine precision (in particular, if
```

```
  RCOND = 0), the matrix is singular to working precision.
  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is REAL array, dimension (NRHS)
  The forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in any
  element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (N)

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  the leading minor of order i of A is
     not positive definite, so the factorization
     could not be completed, and the solution has not
     been computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine zptsv (N, NRHS, D, E, B, LDB, INFO)
            ZPTSV computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine zptsv (integer N, integer NRHS, double precision, dimension( * )
       D, complex*16, dimension( * ) E, complex*16, dimension( ldb, * ) B,
       integer LDB, integer INFO)
        ZPTSV computes the solution to system of linear equations A * X = B
       for PT matrices

Purpose:
   ZPTSV computes the solution to a complex system of linear equations
   A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal
   matrix, and X and B are N-by-NRHS matrices.

   A is factored as A = L*D*L**H, and the factored form of A is then
   used to solve the system of equations.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the factorization A = L*D*L**H.

 E
   E is COMPLEX*16 array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**H factorization of
```

```
  A.  E can also be regarded as the superdiagonal of the unit
  bidiagonal factor U from the U**H*D*U factorization of A.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  On entry, the N-by-NRHS right hand side matrix B.
  On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, the leading minor of order i is not
     positive definite, and the solution has not been
     computed.  The factorization has not been completed unless i = N.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zptsvx (FACT, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, RCOND,
           FERR, BERR, WORK, RWORK, INFO)
            ZPTSVX computes the solution to system of linear equations A * X =
           B for PT matrices

Function/Subroutine Documentation
   subroutine zptsvx (character FACT, integer N, integer NRHS, double
       precision, dimension( * ) D, complex*16, dimension( * ) E, double
       precision, dimension( * ) DF, complex*16, dimension( * ) EF,
       complex*16, dimension( ldb, * ) B, integer LDB, complex*16, dimension(
```

```
      ldx, * ) X, integer LDX, double precision RCOND, double precision,
      dimension( * ) FERR, double precision, dimension( * ) BERR, complex*16,
      dimension( * ) WORK, double precision, dimension( * ) RWORK, integer
      INFO)
       ZPTSVX computes the solution to system of linear equations A * X = B
      for PT matrices

Purpose:
   ZPTSVX uses the factorization A = L*D*L**H to compute the solution
   to a complex system of linear equations A*X = B, where A is an
   N-by-N Hermitian positive definite tridiagonal matrix and X and B
   are N-by-NRHS matrices.

   Error bounds on the solution and a condition estimate are also provided.

Description:

   The following steps are performed:

   1. If FACT = 'N', the matrix A is factored as A = L*D*L**H, where L
      is a unit lower bidiagonal matrix and D is diagonal.  The
      factorization can also be regarded as having the form
      A = U**H*D*U.

   2. If the leading i-by-i principal minor is not positive definite,
      then the routine returns with INFO = i. Otherwise, the factored
      form of A is used to estimate the condition number of the matrix
      A.  If the reciprocal of the condition number is less than machine
      precision, INFO = N+1 is returned as a warning, but the routine
      still goes on to solve for X and compute error bounds as
      described below.

   3. The system of equations is solved for X using the factored form of A.

   4. Iterative refinement is applied to improve the computed solution
      matrix and calculate error bounds and backward error estimates for it.

Parameters:

 FACT
   FACT is CHARACTER*1
   Specifies whether or not the factored form of the matrix
   A is supplied on entry.
   = 'F':  On entry, DF and EF contain the factored form of A.
           D, E, DF, and EF will not be modified.
   = 'N':  The matrix A will be copied to DF and EF and factored.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.
```

```
NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrices B and X.  NRHS >= 0.

D
  D is DOUBLE PRECISION array, dimension (N)
  The n diagonal elements of the tridiagonal matrix A.

E
  E is COMPLEX*16 array, dimension (N-1)
  The (n-1) subdiagonal elements of the tridiagonal matrix A.

DF
  DF is DOUBLE PRECISION array, dimension (N)
  If FACT = 'F', then DF is an input argument and on entry
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**H factorization of A.
  If FACT = 'N', then DF is an output argument and on exit
  contains the n diagonal elements of the diagonal matrix D
  from the L*D*L**H factorization of A.

EF
  EF is COMPLEX*16 array, dimension (N-1)
  If FACT = 'F', then EF is an input argument and on entry
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**H factorization of A.
  If FACT = 'N', then EF is an output argument and on exit
  contains the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the L*D*L**H factorization of A.

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The N-by-NRHS right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

RCOND
  RCOND is DOUBLE PRECISION
```

```
  The reciprocal condition number of the matrix A.  If RCOND
  is less than the machine precision (in particular, if
  RCOND = 0), the matrix is singular to working precision.
  This condition is indicated by a return code of INFO > 0.

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in any
  element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX*16 array, dimension (N)

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  if INFO = i, and i is
  <= N:  the leading minor of order i of A is
     not positive definite, so the factorization
     could not be completed, and the solution has not
     been computed. RCOND = 0 is returned.
  = N+1: U is nonsingular, but RCOND is less than machine
     precision, meaning that the matrix is singular
     to working precision.  Nevertheless, the
     solution and error bounds are computed because
     there are a number of situations where the
     computed solution can be more accurate than the
     value of RCOND would suggest.

SYNOPSIS
   Functions/Subroutines
       subroutine dptcon (N, D, E, ANORM, RCOND, WORK, INFO)
           DPTCON

Function/Subroutine Documentation
   subroutine dptcon (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision ANORM, double precision
       RCOND, double precision, dimension( * ) WORK, integer INFO)
       DPTCON

Purpose:
   DPTCON computes the reciprocal of the condition number (in the
   1-norm) of a real symmetric positive definite tridiagonal matrix
   using the factorization A = L*D*L**T or A = U**T*D*U computed by
   DPTTRF.

   Norm(inv(A)) is computed by a direct method, and the reciprocal of
   the condition number is computed as
      RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization of A, as computed by DPTTRF.

 E
   E is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) off-diagonal elements of the unit bidiagonal factor
   U or L from the factorization of A,  as computed by DPTTRF.

 ANORM
   ANORM is DOUBLE PRECISION
   The 1-norm of the original matrix A.

 RCOND
   RCOND is DOUBLE PRECISION
```

```
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the
  1-norm of inv(A) computed in this routine.

WORK
  WORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dpteqr (COMPZ, N, D, E, Z, LDZ, WORK, INFO)
           DPTEQR

Function/Subroutine Documentation
   subroutine dpteqr (character COMPZ, integer N, double precision, dimension(
       * ) D, double precision, dimension( * ) E, double precision, dimension(
       ldz, * ) Z, integer LDZ, double precision, dimension( * ) WORK, integer
       INFO)
       DPTEQR

Purpose:
   DPTEQR computes all eigenvalues and, optionally, eigenvectors of a
   symmetric positive definite tridiagonal matrix by first factoring the
   matrix using DPTTRF, and then calling DBDSQR to compute the singular
   values of the bidiagonal factor.

   This routine computes the eigenvalues of the positive definite
   tridiagonal matrix to high relative accuracy.  This means that if the
   eigenvalues range over many orders of magnitude in size, then the
   small eigenvalues and corresponding eigenvectors will be computed
   more accurately than, for example, with the standard QR method.

   The eigenvectors of a full or band symmetric positive definite matrix
   can also be found if DSYTRD, DSPTRD, or DSBTRD has been used to
   reduce this matrix to tridiagonal form. (The reduction to tridiagonal
   form, however, may preclude the possibility of obtaining high
   relative accuracy in the small eigenvalues of the original matrix, if
   these eigenvalues range over many orders of magnitude.)

Parameters:

 COMPZ
   COMPZ is CHARACTER*1
   = 'N':  Compute eigenvalues only.
   = 'V':  Compute eigenvectors of original symmetric
```

```
     matrix also.  Array Z contains the orthogonal
     matrix used to reduce the original matrix to tridiagonal form.
  = 'I':  Compute eigenvectors of tridiagonal matrix also.

N
  N is INTEGER
  The order of the matrix.  N >= 0.

D
  D is DOUBLE PRECISION array, dimension (N)
  On entry, the n diagonal elements of the tridiagonal matrix.
  On normal exit, D contains the eigenvalues, in descending order.

E
  E is DOUBLE PRECISION array, dimension (N-1)
  On entry, the (n-1) subdiagonal elements of the tridiagonal matrix.
  On exit, E has been destroyed.

Z
  Z is DOUBLE PRECISION array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the orthogonal matrix used in the
  reduction to tridiagonal form.
  On exit, if COMPZ = 'V', the orthonormal eigenvectors of the
  original symmetric matrix;
  if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix.
  If INFO > 0 on exit, Z contains the eigenvectors associated
  with only the stored eigenvalues.
  If  COMPZ = 'N', then Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, and i is:
  <= N  the Cholesky factorization of the matrix could
     not be performed because the i-th principal minor
     was not positive definite.
  > N   the SVD algorithm failed to converge;
     if INFO = N+i, i off-diagonal elements of the
     bidiagonal factor did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dptrfs (N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR, BERR,
           WORK, INFO)
           DPTRFS

Function/Subroutine Documentation
   subroutine dptrfs (integer N, integer NRHS, double precision, dimension( *
       ) D, double precision, dimension( * ) E, double precision, dimension( *
       ) DF, double precision, dimension( * ) EF, double precision, dimension(
       ldb, * ) B, integer LDB, double precision, dimension( ldx, * ) X,
       integer LDX, double precision, dimension( * ) FERR, double precision,
       dimension( * ) BERR, double precision, dimension( * ) WORK, integer
       INFO)
       DPTRFS

Purpose:
   DPTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive definite
   and tridiagonal, and provides error bounds and backward error
   estimates for the solution.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the tridiagonal matrix A.

 E
   E is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) subdiagonal elements of the tridiagonal matrix A.

 DF
   DF is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization computed by DPTTRF.
```

```
 EF
   EF is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) subdiagonal elements of the unit bidiagonal factor
   L from the factorization computed by DPTTRF.

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   The right hand side matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 X
   X is DOUBLE PRECISION array, dimension (LDX,NRHS)
   On entry, the solution matrix X, as computed by DPTTRS.
   On exit, the improved solution matrix X.

 LDX
   LDX is INTEGER
   The leading dimension of the array X.  LDX >= max(1,N).

 FERR
   FERR is DOUBLE PRECISION array, dimension (NRHS)
   The forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).

 BERR
   BERR is DOUBLE PRECISION array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is DOUBLE PRECISION array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.

SYNOPSIS
   Functions/Subroutines
       subroutine dpttrf (N, D, E, INFO)
           DPTTRF

Function/Subroutine Documentation
   subroutine dpttrf (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) E, integer INFO)
       DPTTRF

Purpose:
   DPTTRF computes the L*D*L**T factorization of a real symmetric
   positive definite tridiagonal matrix A.  The factorization may also
   be regarded as having the form A = U**T*D*U.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the L*D*L**T factorization of A.

 E
   E is DOUBLE PRECISION array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**T factorization of A.
   E can also be regarded as the superdiagonal of the unit
   bidiagonal factor U from the U**T*D*U factorization of A.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, the leading minor of order k is not
      positive definite; if k < N, the factorization could not
      be completed, while if k = N, the factorization was
      completed, but D(N) <= 0.

SYNOPSIS
   Functions/Subroutines
       subroutine dpttrs (N, NRHS, D, E, B, LDB, INFO)
           DPTTRS

Function/Subroutine Documentation
   subroutine dpttrs (integer N, integer NRHS, double precision, dimension( *
       ) D, double precision, dimension( * ) E, double precision, dimension(
       ldb, * ) B, integer LDB, integer INFO)
       DPTTRS

Purpose:
   DPTTRS solves a tridiagonal system of the form
      A * X = B
   using the L*D*L**T factorization of A computed by DPTTRF.  D is a
   diagonal matrix specified in the vector D, L is a unit bidiagonal
   matrix whose subdiagonal is specified in the vector E, and X and B
   are N by NRHS matrices.

Parameters:

 N
   N is INTEGER
   The order of the tridiagonal matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   L*D*L**T factorization of A.

 E
   E is DOUBLE PRECISION array, dimension (N-1)
   The (n-1) subdiagonal elements of the unit bidiagonal factor
   L from the L*D*L**T factorization of A.  E can also be regarded
   as the superdiagonal of the unit bidiagonal factor U from the
   factorization A = U**T*D*U.

 B
```

```
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side vectors B for the system of linear equations.
  On exit, the solution vectors, X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine dptts2 (N, NRHS, D, E, B, LDB)
           DPTTS2 solves a tridiagonal system of the form AX=B using the L D
           LH factorization computed by spttrf.

Function/Subroutine Documentation
   subroutine dptts2 (integer N, integer NRHS, double precision, dimension( *
       ) D, double precision, dimension( * ) E, double precision, dimension(
       ldb, * ) B, integer LDB)
       DPTTS2 solves a tridiagonal system of the form AX=B using the L D LH
       factorization computed by spttrf.

Purpose:
   DPTTS2 solves a tridiagonal system of the form
      A * X = B
   using the L*D*L**T factorization of A computed by DPTTRF.  D is a
   diagonal matrix specified in the vector D, L is a unit bidiagonal
   matrix whose subdiagonal is specified in the vector E, and X and B
   are N by NRHS matrices.

Parameters:

 N
```

```
  N is INTEGER
  The order of the tridiagonal matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

D
  D is DOUBLE PRECISION array, dimension (N)
  The n diagonal elements of the diagonal matrix D from the
  L*D*L**T factorization of A.

E
  E is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) subdiagonal elements of the unit bidiagonal factor
  L from the L*D*L**T factorization of A.  E can also be regarded
  as the superdiagonal of the unit bidiagonal factor U from the
  factorization A = U**T*D*U.

B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side vectors B for the system of linear equations.
  On exit, the solution vectors, X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

SYNOPSIS
   Functions/Subroutines
       subroutine sptcon (N, D, E, ANORM, RCOND, WORK, INFO)
           SPTCON

Function/Subroutine Documentation
   subroutine sptcon (integer N, real, dimension( * ) D, real, dimension( * )
       E, real ANORM, real RCOND, real, dimension( * ) WORK, integer INFO)
       SPTCON

Purpose:
   SPTCON computes the reciprocal of the condition number (in the
   1-norm) of a real symmetric positive definite tridiagonal matrix
   using the factorization A = L*D*L**T or A = U**T*D*U computed by
   SPTTRF.

   Norm(inv(A)) is computed by a direct method, and the reciprocal of
   the condition number is computed as
      RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization of A, as computed by SPTTRF.

 E
   E is REAL array, dimension (N-1)
   The (n-1) off-diagonal elements of the unit bidiagonal factor
   U or L from the factorization of A,  as computed by SPTTRF.

 ANORM
   ANORM is REAL
   The 1-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
```

```
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the
   1-norm of inv(A) computed in this routine.

 WORK
   WORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine spteqr (COMPZ, N, D, E, Z, LDZ, WORK, INFO)
           SPTEQR

Function/Subroutine Documentation
   subroutine spteqr (character COMPZ, integer N, real, dimension( * ) D,
       real, dimension( * ) E, real, dimension( ldz, * ) Z, integer LDZ, real,
       dimension( * ) WORK, integer INFO)
       SPTEQR

Purpose:
   SPTEQR computes all eigenvalues and, optionally, eigenvectors of a
   symmetric positive definite tridiagonal matrix by first factoring the
   matrix using SPTTRF, and then calling SBDSQR to compute the singular
   values of the bidiagonal factor.

   This routine computes the eigenvalues of the positive definite
   tridiagonal matrix to high relative accuracy.  This means that if the
   eigenvalues range over many orders of magnitude in size, then the
   small eigenvalues and corresponding eigenvectors will be computed
   more accurately than, for example, with the standard QR method.

   The eigenvectors of a full or band symmetric positive definite matrix
   can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to
   reduce this matrix to tridiagonal form. (The reduction to tridiagonal
   form, however, may preclude the possibility of obtaining high
   relative accuracy in the small eigenvalues of the original matrix, if
   these eigenvalues range over many orders of magnitude.)

Parameters:

 COMPZ
   COMPZ is CHARACTER*1
   = 'N':  Compute eigenvalues only.
   = 'V':  Compute eigenvectors of original symmetric
      matrix also.  Array Z contains the orthogonal
```

```
     matrix used to reduce the original matrix to tridiagonal form.
  = 'I':  Compute eigenvectors of tridiagonal matrix also.

N
  N is INTEGER
  The order of the matrix.  N >= 0.

D
  D is REAL array, dimension (N)
  On entry, the n diagonal elements of the tridiagonal matrix.
  On normal exit, D contains the eigenvalues, in descending order.

E
  E is REAL array, dimension (N-1)
  On entry, the (n-1) subdiagonal elements of the tridiagonal matrix.
  On exit, E has been destroyed.

Z
  Z is REAL array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the orthogonal matrix used in the
  reduction to tridiagonal form.
  On exit, if COMPZ = 'V', the orthonormal eigenvectors of the
  original symmetric matrix;
  if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix.
  If INFO > 0 on exit, Z contains the eigenvectors associated
  with only the stored eigenvalues.
  If  COMPZ = 'N', then Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK
  WORK is REAL array, dimension (4*N)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
   Functions/Subroutines
       subroutine sptrfs (N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR, BERR,
           WORK, INFO)
           SPTRFS

Function/Subroutine Documentation
   subroutine sptrfs (integer N, integer NRHS, real, dimension( * ) D, real,
       dimension( * ) E, real, dimension( * ) DF, real, dimension( * ) EF,
       real, dimension( ldb, * ) B, integer LDB, real, dimension( ldx, * ) X,
       integer LDX, real, dimension( * ) FERR, real, dimension( * ) BERR,
       real, dimension( * ) WORK, integer INFO)
       SPTRFS

Purpose:
   SPTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is symmetric positive definite
   and tridiagonal, and provides error bounds and backward error
   estimates for the solution.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the tridiagonal matrix A.

 E
   E is REAL array, dimension (N-1)
   The (n-1) subdiagonal elements of the tridiagonal matrix A.

 DF
   DF is REAL array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization computed by SPTTRF.

 EF
   EF is REAL array, dimension (N-1)
   The (n-1) subdiagonal elements of the unit bidiagonal factor
   L from the factorization computed by SPTTRF.
```

```
 B
   B is REAL array, dimension (LDB,NRHS)
   The right hand side matrix B.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 X
   X is REAL array, dimension (LDX,NRHS)
   On entry, the solution matrix X, as computed by SPTTRS.
   On exit, the improved solution matrix X.

 LDX
   LDX is INTEGER
   The leading dimension of the array X.  LDX >= max(1,N).

 FERR
   FERR is REAL array, dimension (NRHS)
   The forward error bound for each solution vector
   X(j) (the j-th column of the solution matrix X).
   If XTRUE is the true solution corresponding to X(j), FERR(j)
   is an estimated upper bound for the magnitude of the largest
   element in (X(j) - XTRUE) divided by the magnitude of the
   largest element in X(j).

 BERR
   BERR is REAL array, dimension (NRHS)
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is REAL array, dimension (2*N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine spttrf (N, D, E, INFO)
           SPTTRF

Function/Subroutine Documentation
   subroutine spttrf (integer N, real, dimension( * ) D, real, dimension( * )
       E, integer INFO)
       SPTTRF

Purpose:
   SPTTRF computes the L*D*L**T factorization of a real symmetric
   positive definite tridiagonal matrix A.  The factorization may also
   be regarded as having the form A = U**T*D*U.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is REAL array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the L*D*L**T factorization of A.

 E
   E is REAL array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**T factorization of A.
   E can also be regarded as the superdiagonal of the unit
   bidiagonal factor U from the U**T*D*U factorization of A.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, the leading minor of order k is not
      positive definite; if k < N, the factorization could not
      be completed, while if k = N, the factorization was
      completed, but D(N) <= 0.

SYNOPSIS
   Functions/Subroutines
       subroutine spttrs (N, NRHS, D, E, B, LDB, INFO)
           SPTTRS

Function/Subroutine Documentation
   subroutine spttrs (integer N, integer NRHS, real, dimension( * ) D, real,
       dimension( * ) E, real, dimension( ldb, * ) B, integer LDB, integer
       INFO)
       SPTTRS

Purpose:
   SPTTRS solves a tridiagonal system of the form
      A * X = B
   using the L*D*L**T factorization of A computed by SPTTRF.  D is a
   diagonal matrix specified in the vector D, L is a unit bidiagonal
   matrix whose subdiagonal is specified in the vector E, and X and B
   are N by NRHS matrices.

Parameters:

 N
   N is INTEGER
   The order of the tridiagonal matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   L*D*L**T factorization of A.

 E
   E is REAL array, dimension (N-1)
   The (n-1) subdiagonal elements of the unit bidiagonal factor
   L from the L*D*L**T factorization of A.  E can also be regarded
   as the superdiagonal of the unit bidiagonal factor U from the
   factorization A = U**T*D*U.

 B
```

```
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side vectors B for the system of linear equations.
  On exit, the solution vectors, X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine sptts2 (N, NRHS, D, E, B, LDB)
           SPTTS2 solves a tridiagonal system of the form AX=B using the L D
           LH factorization computed by spttrf.

Function/Subroutine Documentation
   subroutine sptts2 (integer N, integer NRHS, real, dimension( * ) D, real,
       dimension( * ) E, real, dimension( ldb, * ) B, integer LDB)
       SPTTS2 solves a tridiagonal system of the form AX=B using the L D LH
       factorization computed by spttrf.

Purpose:
   SPTTS2 solves a tridiagonal system of the form
      A * X = B
   using the L*D*L**T factorization of A computed by SPTTRF.  D is a
   diagonal matrix specified in the vector D, L is a unit bidiagonal
   matrix whose subdiagonal is specified in the vector E, and X and B
   are N by NRHS matrices.

Parameters:

 N
   N is INTEGER
```

```
  The order of the tridiagonal matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

D
  D is REAL array, dimension (N)
  The n diagonal elements of the diagonal matrix D from the
  L*D*L**T factorization of A.

E
  E is REAL array, dimension (N-1)
  The (n-1) subdiagonal elements of the unit bidiagonal factor
  L from the L*D*L**T factorization of A.  E can also be regarded
  as the superdiagonal of the unit bidiagonal factor U from the
  factorization A = U**T*D*U.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side vectors B for the system of linear equations.
  On exit, the solution vectors, X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

SYNOPSIS
   Functions/Subroutines
       subroutine cptcon (N, D, E, ANORM, RCOND, RWORK, INFO)
           CPTCON

Function/Subroutine Documentation
   subroutine cptcon (integer N, real, dimension( * ) D, complex, dimension( *
       ) E, real ANORM, real RCOND, real, dimension( * ) RWORK, integer INFO)
       CPTCON

Purpose:
   CPTCON computes the reciprocal of the condition number (in the
   1-norm) of a complex Hermitian positive definite tridiagonal matrix
   using the factorization A = L*D*L**H or A = U**H*D*U computed by CPTTRF.

   Norm(inv(A)) is computed by a direct method, and the reciprocal of
   the condition number is computed as
      RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization of A, as computed by CPTTRF.

 E
   E is COMPLEX array, dimension (N-1)
   The (n-1) off-diagonal elements of the unit bidiagonal factor
   U or L from the factorization of A, as computed by CPTTRF.

 ANORM
   ANORM is REAL
   The 1-norm of the original matrix A.

 RCOND
   RCOND is REAL
   The reciprocal of the condition number of the matrix A,
   computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the
```

```
  1-norm of inv(A) computed in this routine.

RWORK
  RWORK is REAL array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine cpteqr (COMPZ, N, D, E, Z, LDZ, WORK, INFO)
           CPTEQR

Function/Subroutine Documentation
   subroutine cpteqr (character COMPZ, integer N, real, dimension( * ) D,
       real, dimension( * ) E, complex, dimension( ldz, * ) Z, integer LDZ,
       real, dimension( * ) WORK, integer INFO)
       CPTEQR

Purpose:
   CPTEQR computes all eigenvalues and, optionally, eigenvectors of a
   symmetric positive definite tridiagonal matrix by first factoring the
   matrix using SPTTRF and then calling CBDSQR to compute the singular
   values of the bidiagonal factor.

   This routine computes the eigenvalues of the positive definite
   tridiagonal matrix to high relative accuracy.  This means that if the
   eigenvalues range over many orders of magnitude in size, then the
   small eigenvalues and corresponding eigenvectors will be computed
   more accurately than, for example, with the standard QR method.

   The eigenvectors of a full or band positive definite Hermitian matrix
   can also be found if CHETRD, CHPTRD, or CHBTRD has been used to
   reduce this matrix to tridiagonal form.  (The reduction to
   tridiagonal form, however, may preclude the possibility of obtaining
   high relative accuracy in the small eigenvalues of the original
   matrix, if these eigenvalues range over many orders of magnitude.)

Parameters:

 COMPZ
   COMPZ is CHARACTER*1
   = 'N':  Compute eigenvalues only.
   = 'V':  Compute eigenvectors of original Hermitian
      matrix also.  Array Z contains the unitary matrix
```

```
     used to reduce the original matrix to tridiagonal form.
  = 'I':  Compute eigenvectors of tridiagonal matrix also.

N
  N is INTEGER
  The order of the matrix.  N >= 0.

D
  D is REAL array, dimension (N)
  On entry, the n diagonal elements of the tridiagonal matrix.
  On normal exit, D contains the eigenvalues, in descending order.

E
  E is REAL array, dimension (N-1)
  On entry, the (n-1) subdiagonal elements of the tridiagonal matrix.
  On exit, E has been destroyed.

Z
  Z is COMPLEX array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the unitary matrix used in the
  reduction to tridiagonal form.
  On exit, if COMPZ = 'V', the orthonormal eigenvectors of the
  original Hermitian matrix;
  if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix.
  If INFO > 0 on exit, Z contains the eigenvectors associated
  with only the stored eigenvalues.
  If  COMPZ = 'N', then Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK
  WORK is REAL array, dimension (4*N)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, and i is:
  <= N  the Cholesky factorization of the matrix could
     not be performed because the i-th principal minor
     was not positive definite.
  > N   the SVD algorithm failed to converge;
     if INFO = N+i, i off-diagonal elements of the
     bidiagonal factor did not converge to zero.

SYNOPSIS
   Functions/Subroutines
       subroutine cptrfs (UPLO, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR,
           BERR, WORK, RWORK, INFO)
           CPTRFS

Function/Subroutine Documentation
   subroutine cptrfs (character UPLO, integer N, integer NRHS, real,
       dimension( * ) D, complex, dimension( * ) E, real, dimension( * ) DF,
       complex, dimension( * ) EF, complex, dimension( ldb, * ) B, integer
       LDB, complex, dimension( ldx, * ) X, integer LDX, real, dimension( * )
       FERR, real, dimension( * ) BERR, complex, dimension( * ) WORK, real,
       dimension( * ) RWORK, integer INFO)
       CPTRFS

Purpose:
   CPTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is Hermitian positive definite
   and tridiagonal, and provides error bounds and backward error
   estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the superdiagonal or the subdiagonal of the
   tridiagonal matrix A is stored and the form of the
   factorization:
   = 'U':  E is the superdiagonal of A, and A = U**H*D*U;
   = 'L':  E is the subdiagonal of A, and A = L*D*L**H.
   (The two forms are equivalent if A is real.)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is REAL array, dimension (N)
   The n real diagonal elements of the tridiagonal matrix A.
```

```
E
  E is COMPLEX array, dimension (N-1)
  The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DF
  DF is REAL array, dimension (N)
  The n diagonal elements of the diagonal matrix D from
  the factorization computed by CPTTRF.

EF
  EF is COMPLEX array, dimension (N-1)
  The (n-1) off-diagonal elements of the unit bidiagonal
  factor U or L from the factorization computed by CPTTRF (see UPLO).

B
  B is COMPLEX array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by CPTTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is REAL array, dimension (NRHS)
  The forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).

BERR
  BERR is REAL array, dimension (NRHS)
  The componentwise relative backward error of each solution
  vector X(j) (i.e., the smallest relative change in
  any element of A or B that makes X(j) an exact solution).

WORK
  WORK is COMPLEX array, dimension (N)

RWORK
```

```
   RWORK is REAL array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cpttrf (N, D, E, INFO)
           CPTTRF

Function/Subroutine Documentation
   subroutine cpttrf (integer N, real, dimension( * ) D, complex, dimension( *
       ) E, integer INFO)
       CPTTRF

Purpose:
   CPTTRF computes the L*D*L**H factorization of a complex Hermitian
   positive definite tridiagonal matrix A.  The factorization may also
   be regarded as having the form A = U**H *D*U.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is REAL array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the L*D*L**H factorization of A.

 E
   E is COMPLEX array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**H factorization of A.
   E can also be regarded as the superdiagonal of the unit
   bidiagonal factor U from the U**H *D*U factorization of A.

 INFO
   INFO is INTEGER
```

```
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, the leading minor of order k is not
      positive definite; if k < N, the factorization could not
      be completed, while if k = N, the factorization was
      completed, but D(N) <= 0.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cpttrs (UPLO, N, NRHS, D, E, B, LDB, INFO)
           CPTTRS

Function/Subroutine Documentation
   subroutine cpttrs (character UPLO, integer N, integer NRHS, real,
       dimension( * ) D, complex, dimension( * ) E, complex, dimension( ldb, *
       ) B, integer LDB, integer INFO)
       CPTTRS

Purpose:
   CPTTRS solves a tridiagonal system of the form
      A * X = B
   using the factorization A = U**H*D*U or A = L*D*L**H computed by CPTTRF.
   D is a diagonal matrix specified in the vector D, U (or L) is a unit
   bidiagonal matrix whose superdiagonal (subdiagonal) is specified in
   the vector E, and X and B are N by NRHS matrices.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies the form of the factorization and whether the
   vector E is the superdiagonal of the upper bidiagonal factor
   U or the subdiagonal of the lower bidiagonal factor L.
```

```
  = 'U':  A = U**H*D*U, E is the superdiagonal of U
  = 'L':  A = L*D*L**H, E is the subdiagonal of L

N
  N is INTEGER
  The order of the tridiagonal matrix A.  N >= 0.

NRHS
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

D
  D is REAL array, dimension (N)
  The n diagonal elements of the diagonal matrix D from the
  factorization A = U**H*D*U or A = L*D*L**H.

E
  E is COMPLEX array, dimension (N-1)
  If UPLO = 'U', the (n-1) superdiagonal elements of the unit
  bidiagonal factor U from the factorization A = U**H*D*U.
  If UPLO = 'L', the (n-1) subdiagonal elements of the unit
  bidiagonal factor L from the factorization A = L*D*L**H.

B
  B is REAL array, dimension (LDB,NRHS)
  On entry, the right hand side vectors B for the system of linear equations.
  On exit, the solution vectors, X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

INFO
  INFO is INTEGER
  = 0: successful exit
  < 0: if INFO = -k, the k-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine cptts2 (IUPLO, N, NRHS, D, E, B, LDB)
           CPTTS2 solves a tridiagonal system of the form AX=B using the L D
           LH factorization computed by spttrf.

Function/Subroutine Documentation
   subroutine cptts2 (integer IUPLO, integer N, integer NRHS, real, dimension(
       * ) D, complex, dimension( * ) E, complex, dimension( ldb, * ) B,
       integer LDB)
       CPTTS2 solves a tridiagonal system of the form AX=B using the L D LH
       factorization computed by spttrf.

Purpose:
   CPTTS2 solves a tridiagonal system of the form
     A * X = B
```

```
  using the factorization A = U**H*D*U or A = L*D*L**H computed by CPTTRF.
  D is a diagonal matrix specified in the vector D, U (or L) is a unit
  bidiagonal matrix whose superdiagonal (subdiagonal) is specified in
  the vector E, and X and B are N by NRHS matrices.

Parameters:

 IUPLO
   IUPLO is INTEGER
   Specifies the form of the factorization and whether the
   vector E is the superdiagonal of the upper bidiagonal factor
   U or the subdiagonal of the lower bidiagonal factor L.
   = 1:  A = U**H *D*U, E is the superdiagonal of U
   = 0:  A = L*D*L**H, E is the subdiagonal of L

 N
   N is INTEGER
   The order of the tridiagonal matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is REAL array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization A = U**H *D*U or A = L*D*L**H.

 E
   E is COMPLEX array, dimension (N-1)
   If IUPLO = 1, the (n-1) superdiagonal elements of the unit
   bidiagonal factor U from the factorization A = U**H*D*U.
   If IUPLO = 0, the (n-1) subdiagonal elements of the unit
   bidiagonal factor L from the factorization A = L*D*L**H.

 B
   B is REAL array, dimension (LDB,NRHS)
   On entry, the right hand side vectors B for the system of linear equations.
   On exit, the solution vectors, X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

SYNOPSIS
   Functions/Subroutines
       subroutine zptcon (N, D, E, ANORM, RCOND, RWORK, INFO)
           ZPTCON

Function/Subroutine Documentation
   subroutine zptcon (integer N, double precision, dimension( * ) D,
       complex*16, dimension( * ) E, double precision ANORM, double precision
       RCOND, double precision, dimension( * ) RWORK, integer INFO)
       ZPTCON

Purpose:
   ZPTCON computes the reciprocal of the condition number (in the
   1-norm) of a complex Hermitian positive definite tridiagonal matrix
   using the factorization A = L*D*L**H or A = U**H*D*U computed by
   ZPTTRF.

   Norm(inv(A)) is computed by a direct method, and the reciprocal of
   the condition number is computed as
       RCOND = 1 / (ANORM * norm(inv(A))).

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization of A, as computed by ZPTTRF.

 E
   E is COMPLEX*16 array, dimension (N-1)
   The (n-1) off-diagonal elements of the unit bidiagonal factor
   U or L from the factorization of A, as computed by ZPTTRF.

 ANORM
   ANORM is DOUBLE PRECISION
   The 1-norm of the original matrix A.

 RCOND
   RCOND is DOUBLE PRECISION
```

```
  The reciprocal of the condition number of the matrix A,
  computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the
  1-norm of inv(A) computed in this routine.

RWORK
  RWORK is DOUBLE PRECISION array, dimension (N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpteqr (COMPZ, N, D, E, Z, LDZ, WORK, INFO)
           ZPTEQR

Function/Subroutine Documentation
   subroutine zpteqr (character COMPZ, integer N, double precision, dimension(
       * ) D, double precision, dimension( * ) E, complex*16, dimension( ldz,
       * ) Z, integer LDZ, double precision, dimension( * ) WORK, integer
       INFO)
       ZPTEQR

Purpose:
   ZPTEQR computes all eigenvalues and, optionally, eigenvectors of a
   symmetric positive definite tridiagonal matrix by first factoring the
   matrix using DPTTRF and then calling ZBDSQR to compute the singular
   values of the bidiagonal factor.

   This routine computes the eigenvalues of the positive definite
   tridiagonal matrix to high relative accuracy.  This means that if the
   eigenvalues range over many orders of magnitude in size, then the
   small eigenvalues and corresponding eigenvectors will be computed
   more accurately than, for example, with the standard QR method.

   The eigenvectors of a full or band positive definite Hermitian matrix
   can also be found if ZHETRD, ZHPTRD, or ZHBTRD has been used to
   reduce this matrix to tridiagonal form.  (The reduction to
   tridiagonal form, however, may preclude the possibility of obtaining
   high relative accuracy in the small eigenvalues of the original
   matrix, if these eigenvalues range over many orders of magnitude.)

Parameters:

 COMPZ
```

```
  COMPZ is CHARACTER*1
  = 'N':  Compute eigenvalues only.
  = 'V':  Compute eigenvectors of original Hermitian
     matrix also.  Array Z contains the unitary matrix
     used to reduce the original matrix to tridiagonal form.
  = 'I':  Compute eigenvectors of tridiagonal matrix also.

N
  N is INTEGER
  The order of the matrix.  N >= 0.

D
  D is DOUBLE PRECISION array, dimension (N)
  On entry, the n diagonal elements of the tridiagonal matrix.
  On normal exit, D contains the eigenvalues, in descending order.

E
  E is DOUBLE PRECISION array, dimension (N-1)
  On entry, the (n-1) subdiagonal elements of the tridiagonal matrix.
  On exit, E has been destroyed.

Z
  Z is COMPLEX*16 array, dimension (LDZ, N)
  On entry, if COMPZ = 'V', the unitary matrix used in the
  reduction to tridiagonal form.
  On exit, if COMPZ = 'V', the orthonormal eigenvectors of the
  original Hermitian matrix;
  if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix.
  If INFO > 0 on exit, Z contains the eigenvectors associated
  with only the stored eigenvalues.
  If  COMPZ = 'N', then Z is not referenced.

LDZ
  LDZ is INTEGER
  The leading dimension of the array Z.  LDZ >= 1, and if
  COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = i, and i is:
  <= N  the Cholesky factorization of the matrix could
     not be performed because the i-th principal minor
     was not positive definite.
  > N   the SVD algorithm failed to converge;
     if INFO = N+i, i off-diagonal elements of the
```

```
      bidiagonal factor did not converge to zero.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zptrfs (UPLO, N, NRHS, D, E, DF, EF, B, LDB, X, LDX, FERR,
           BERR, WORK, RWORK, INFO)
           ZPTRFS

Function/Subroutine Documentation
   subroutine zptrfs (character UPLO, integer N, integer NRHS, double
       precision, dimension( * ) D, complex*16, dimension( * ) E, double
       precision, dimension( * ) DF, complex*16, dimension( * ) EF,
       complex*16, dimension( ldb, * ) B, integer LDB, complex*16, dimension(
       ldx, * ) X, integer LDX, double precision, dimension( * ) FERR, double
       precision, dimension( * ) BERR, complex*16, dimension( * ) WORK, double
       precision, dimension( * ) RWORK, integer INFO)
       ZPTRFS

Purpose:
   ZPTRFS improves the computed solution to a system of linear
   equations when the coefficient matrix is Hermitian positive definite
   and tridiagonal, and provides error bounds and backward error
   estimates for the solution.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies whether the superdiagonal or the subdiagonal of the
   tridiagonal matrix A is stored and the form of the factorization:
   = 'U':  E is the superdiagonal of A, and A = U**H*D*U;
   = 'L':  E is the subdiagonal of A, and A = L*D*L**H.
   (The two forms are equivalent if A is real.)

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 NRHS
```

```
  NRHS is INTEGER
  The number of right hand sides, i.e., the number of columns
  of the matrix B.  NRHS >= 0.

D
  D is DOUBLE PRECISION array, dimension (N)
  The n real diagonal elements of the tridiagonal matrix A.

E
  E is COMPLEX*16 array, dimension (N-1)
  The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DF
  DF is DOUBLE PRECISION array, dimension (N)
  The n diagonal elements of the diagonal matrix D from
  the factorization computed by ZPTTRF.

EF
  EF is COMPLEX*16 array, dimension (N-1)
  The (n-1) off-diagonal elements of the unit bidiagonal
  factor U or L from the factorization computed by ZPTTRF (see UPLO).

B
  B is COMPLEX*16 array, dimension (LDB,NRHS)
  The right hand side matrix B.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

X
  X is COMPLEX*16 array, dimension (LDX,NRHS)
  On entry, the solution matrix X, as computed by ZPTTRS.
  On exit, the improved solution matrix X.

LDX
  LDX is INTEGER
  The leading dimension of the array X.  LDX >= max(1,N).

FERR
  FERR is DOUBLE PRECISION array, dimension (NRHS)
  The forward error bound for each solution vector
  X(j) (the j-th column of the solution matrix X).
  If XTRUE is the true solution corresponding to X(j), FERR(j)
  is an estimated upper bound for the magnitude of the largest
  element in (X(j) - XTRUE) divided by the magnitude of the
  largest element in X(j).

BERR
  BERR is DOUBLE PRECISION array, dimension (NRHS)
```

```
   The componentwise relative backward error of each solution
   vector X(j) (i.e., the smallest relative change in
   any element of A or B that makes X(j) an exact solution).

 WORK
   WORK is COMPLEX*16 array, dimension (N)

 RWORK
   RWORK is DOUBLE PRECISION array, dimension (N)

 INFO
   INFO is INTEGER
   = 0:  successful exit
   < 0:  if INFO = -i, the i-th argument had an illegal value

Internal Parameters:

   ITMAX is the maximum number of steps of iterative refinement.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpttrf (N, D, E, INFO)
           ZPTTRF

Function/Subroutine Documentation
   subroutine zpttrf (integer N, double precision, dimension( * ) D,
       complex*16, dimension( * ) E, integer INFO)
       ZPTTRF

Purpose:
   ZPTTRF computes the L*D*L**H factorization of a complex Hermitian
   positive definite tridiagonal matrix A.  The factorization may also
   be regarded as having the form A = U**H *D*U.

Parameters:

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry, the n diagonal elements of the tridiagonal matrix
   A.  On exit, the n diagonal elements of the diagonal matrix
   D from the L*D*L**H factorization of A.
```

```
 E
   E is COMPLEX*16 array, dimension (N-1)
   On entry, the (n-1) subdiagonal elements of the tridiagonal
   matrix A.  On exit, the (n-1) subdiagonal elements of the
   unit bidiagonal factor L from the L*D*L**H factorization of A.
   E can also be regarded as the superdiagonal of the unit
   bidiagonal factor U from the U**H *D*U factorization of A.

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
   > 0: if INFO = k, the leading minor of order k is not
      positive definite; if k < N, the factorization could not
      be completed, while if k = N, the factorization was
      completed, but D(N) <= 0.
```

SYNOPSIS
   Functions/Subroutines
       subroutine zpttrs (UPLO, N, NRHS, D, E, B, LDB, INFO)
           ZPTTRS

Function/Subroutine Documentation
   subroutine zpttrs (character UPLO, integer N, integer NRHS, double
       precision, dimension( * ) D, complex*16, dimension( * ) E, complex*16,
       dimension( ldb, * ) B, integer LDB, integer INFO)
       ZPTTRS

Purpose:
   ZPTTRS solves a tridiagonal system of the form
      A * X = B
   using the factorization A = U**H *D* U or A = L*D*L**H computed by ZPTTRF.
   D is a diagonal matrix specified in the vector D, U (or L) is a unit
```

```
  bidiagonal matrix whose superdiagonal (subdiagonal) is specified in
  the vector E, and X and B are N by NRHS matrices.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies the form of the factorization and whether the
   vector E is the superdiagonal of the upper bidiagonal factor
   U or the subdiagonal of the lower bidiagonal factor L.
   = 'U':  A = U**H *D*U, E is the superdiagonal of U
   = 'L':  A = L*D*L**H, E is the subdiagonal of L

 N
   N is INTEGER
   The order of the tridiagonal matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization A = U**H *D*U or A = L*D*L**H.

 E
   E is COMPLEX*16 array, dimension (N-1)
   If UPLO = 'U', the (n-1) superdiagonal elements of the unit
   bidiagonal factor U from the factorization A = U**H*D*U.
   If UPLO = 'L', the (n-1) subdiagonal elements of the unit
   bidiagonal factor L from the factorization A = L*D*L**H.

 B
   B is DOUBLE PRECISION array, dimension (LDB,NRHS)
   On entry, the right hand side vectors B for the system of linear equations.
   On exit, the solution vectors, X.

 LDB
   LDB is INTEGER
   The leading dimension of the array B.  LDB >= max(1,N).

 INFO
   INFO is INTEGER
   = 0: successful exit
   < 0: if INFO = -k, the k-th argument had an illegal value
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine zptts2 (IUPLO, N, NRHS, D, E, B, LDB)
          ZPTTS2 solves a tridiagonal system of the form AX=B using the L D
          LH factorization computed by spttrf.

Function/Subroutine Documentation
   subroutine zptts2 (integer IUPLO, integer N, integer NRHS, double
       precision, dimension( * ) D, complex*16, dimension( * ) E, complex*16,
       dimension( ldb, * ) B, integer LDB)
       ZPTTS2 solves a tridiagonal system of the form AX=B using the L D LH
       factorization computed by spttrf.

Purpose:
   ZPTTS2 solves a tridiagonal system of the form
      A * X = B
   using the factorization A = U**H *D*U or A = L*D*L**H computed by ZPTTRF.
   D is a diagonal matrix specified in the vector D, U (or L) is a unit
   bidiagonal matrix whose superdiagonal (subdiagonal) is specified in
   the vector E, and X and B are N by NRHS matrices.

Parameters:

 IUPLO
   IUPLO is INTEGER
   Specifies the form of the factorization and whether the
   vector E is the superdiagonal of the upper bidiagonal factor
   U or the subdiagonal of the lower bidiagonal factor L.
   = 1:  A = U**H *D*U, E is the superdiagonal of U
   = 0:  A = L*D*L**H, E is the subdiagonal of L

 N
   N is INTEGER
   The order of the tridiagonal matrix A.  N >= 0.

 NRHS
   NRHS is INTEGER
   The number of right hand sides, i.e., the number of columns
   of the matrix B.  NRHS >= 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The n diagonal elements of the diagonal matrix D from the
   factorization A = U**H *D*U or A = L*D*L**H.

 E
   E is COMPLEX*16 array, dimension (N-1)
   If IUPLO = 1, the (n-1) superdiagonal elements of the unit
   bidiagonal factor U from the factorization A = U**H*D*U.
   If IUPLO = 0, the (n-1) subdiagonal elements of the unit
   bidiagonal factor L from the factorization A = L*D*L**H.
```

```
B
  B is DOUBLE PRECISION array, dimension (LDB,NRHS)
  On entry, the right hand side vectors B for the system of
  linear equations.
  On exit, the solution vectors, X.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,N).

SYNOPSIS
   Functions/Subroutines
       logical function disnan (DIN)
           DISNAN tests input for NaN.

Function/Subroutine Documentation
   logical function disnan (double precision DIN)
       DISNAN tests input for NaN.

Purpose:
   DISNAN returns .TRUE. if its argument is NaN, and .FALSE.
   otherwise.  To be replaced by the Fortran 2003 intrinsic in the future.

Parameters:

 DIN
   DIN is DOUBLE PRECISION
   Input to test for NaN.

SYNOPSIS
   Functions/Subroutines
       subroutine dlabad (SMALL, LARGE)
           DLABAD

Function/Subroutine Documentation
   subroutine dlabad (double precision SMALL, double precision LARGE)
       DLABAD

Purpose:
   DLABAD takes as input the values computed by DLAMCH for underflow and
   overflow, and returns the square root of each of these values if the
   log of LARGE is sufficiently large.  This subroutine is intended to
   identify machines with a large exponent range, such as the Crays, and
   redefine the underflow and overflow limits to be the square roots of
   the values computed by DLAMCH.  This subroutine is needed because
   DLAMCH does not compensate for poor arithmetic in the upper half of
   the exponent range, as is found on a Cray.

Parameters:

 SMALL
   SMALL is DOUBLE PRECISION
   On entry, the underflow threshold as computed by DLAMCH.
   On exit, if LOG10(LARGE) is sufficiently large, the square
   root of SMALL, otherwise unchanged.

 LARGE
   LARGE is DOUBLE PRECISION
   On entry, the overflow threshold as computed by DLAMCH.
   On exit, if LOG10(LARGE) is sufficiently large, the square
   root of LARGE, otherwise unchanged.

======================================================================
Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dlacpy (UPLO, M, N, A, LDA, B, LDB)
           DLACPY copies all or part of one two-dimensional array to another.

Function/Subroutine Documentation
   subroutine dlacpy (character UPLO, integer M, integer N, double precision,
       dimension( lda, * ) A, integer LDA, double precision, dimension( ldb, *
       ) B, integer LDB)
       DLACPY copies all or part of one two-dimensional array to another.

Purpose:
   DLACPY copies all or part of a two-dimensional matrix A to another matrix B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies the part of the matrix A to be copied to B.
   = 'U':      Upper triangular part
   = 'L':      Lower triangular part
   Otherwise:  All of the matrix A

 M
```

```
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The m by n matrix A.  If UPLO = 'U', only the upper triangle
  or trapezoid is accessed; if UPLO = 'L', only the lower
  triangle or trapezoid is accessed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is DOUBLE PRECISION array, dimension (LDB,N)
  On exit, B = A in the locations specified by UPLO.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,M).

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dladiv (A, B, C, D, P, Q)
           DLADIV performs complex division in real arithmetic, avoiding
           unnecessary overflow.
       subroutine dladiv1 (A, B, C, D, P, Q)
       double precision function dladiv2 (A, B, C, D, R, T)

Function/Subroutine Documentation
   subroutine dladiv (double precision A, double precision B, double precision
       C, double precision D, double precision P, double precision Q)
       DLADIV performs complex division in real arithmetic, avoiding
       unnecessary overflow.

Purpose:
   DLADIV performs complex division in  real arithmetic
```

```
                    a + i*b
          p + i*q = ---------
                    c + i*d

   The algorithm is due to Michael Baudin and Robert L. Smith
   and can be found in the paper
   "A Robust Complex Division in Scilab"

Parameters:

 A
   A is DOUBLE PRECISION

 B
   B is DOUBLE PRECISION

 C
   C is DOUBLE PRECISION

 D
   D is DOUBLE PRECISION
   The scalars a, b, c, and d in the above expression.

 P
   P is DOUBLE PRECISION

 Q
   Q is DOUBLE PRECISION
   The scalars p and q in the above expression.

   subroutine dladiv1 (double precision A, double precision B, double
       precision C, double precision D, double precision P, double precision
       Q)
   double precision function dladiv2 (double precision A, double precision B,
       double precision C, double precision D, double precision R, double
       precision T)
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dlae2 (A, B, C, RT1, RT2)
           DLAE2 computes the eigenvalues of a 2-by-2 symmetric matrix.

Function/Subroutine Documentation
   subroutine dlae2 (double precision A, double precision B, double precision
       C, double precision RT1, double precision RT2)
       DLAE2 computes the eigenvalues of a 2-by-2 symmetric matrix.

Purpose:
   DLAE2  computes the eigenvalues of a 2-by-2 symmetric matrix
      [  A   B  ]
      [  B   C  ].
   On return, RT1 is the eigenvalue of larger absolute value, and RT2
   is the eigenvalue of smaller absolute value.

Parameters:

 A
   A is DOUBLE PRECISION
   The (1,1) element of the 2-by-2 matrix.

 B
   B is DOUBLE PRECISION
   The (1,2) and (2,1) elements of the 2-by-2 matrix.

 C
   C is DOUBLE PRECISION
   The (2,2) element of the 2-by-2 matrix.

 RT1
   RT1 is DOUBLE PRECISION
   The eigenvalue of larger absolute value.

 RT2
   RT2 is DOUBLE PRECISION
   The eigenvalue of smaller absolute value.

Further Details:

   RT1 is accurate to a few ulps barring over/underflow.
```

```
RT2 may be inaccurate if there is massive cancellation in the
determinant A*C-B*B; higher precision or correctly rounded or
correctly truncated arithmetic would be needed to compute RT2
accurately in all cases.

Overflow is possible only if RT1 is within a factor of 5 of overflow.
Underflow is harmless if the input data is 0 or exceeds
underflow_threshold / macheps.
```

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine dlaebz (IJOB, NITMAX, N, MMAX, MINP, NBMIN, ABSTOL, RELTOL,
           PIVMIN, D, E, E2, NVAL, AB, C, MOUT, NAB, WORK, IWORK, INFO)
           DLAEBZ computes the number of eigenvalues of a real symmetric
           tridiagonal matrix which are less than or equal to a given value,
           and performs other tasks required by the routine sstebz.

Function/Subroutine Documentation
   subroutine dlaebz (integer IJOB, integer NITMAX, integer N, integer MMAX,
       integer MINP, integer NBMIN, double precision ABSTOL, double precision
       RELTOL, double precision PIVMIN, double precision, dimension( * ) D,
       double precision, dimension( * ) E, double precision, dimension( * )
       E2, integer, dimension( * ) NVAL, double precision, dimension( mmax, *
       ) AB, double precision, dimension( * ) C, integer MOUT, integer,
       dimension( mmax, * ) NAB, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
       DLAEBZ computes the number of eigenvalues of a real symmetric
       tridiagonal matrix which are less than or equal to a given value, and
       performs other tasks required by the routine sstebz.

Purpose:
   DLAEBZ contains the iteration loops which compute and use the
   function N(w), which is the count of eigenvalues of a symmetric
   tridiagonal matrix T less than or equal to its argument  w.  It
   performs a choice of two types of loops:

   IJOB=1, followed by
   IJOB=2: It takes as input a list of intervals and returns a list of
      sufficiently small intervals whose union contains the same
      eigenvalues as the union of the original intervals.
      The input intervals are (AB(j,1),AB(j,2)], j=1,...,MINP.
      The output interval (AB(j,1),AB(j,2)] will contain
      eigenvalues NAB(j,1)+1,...,NAB(j,2), where 1 <= j <= MOUT.

   IJOB=3: It performs a binary search in each input interval
      (AB(j,1),AB(j,2)] for a point  w(j)  such that
      N(w(j))=NVAL(j), and uses  C(j)  as the starting point of
      the search.  If such a w(j) is found, then on output
      AB(j,1)=AB(j,2)=w.  If no such w(j) is found, then on output
      (AB(j,1),AB(j,2)] will be a small interval containing the
      point where N(w) jumps through NVAL(j), unless that point
      lies outside the initial interval.

   Note that the intervals are in all cases half-open intervals,
   i.e., of the form  (a,b] , which includes  b  but not  a .

   To avoid underflow, the matrix should be scaled so that its largest
   element is no greater than  overflow**(1/2) * underflow**(1/4)
   in absolute value.  To assure the most accurate computation
   of small eigenvalues, the matrix should be scaled to be
```

```
  not much smaller than that, either.

  See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal
  Matrix", Report CS41, Computer Science Dept., Stanford
  University, July 21, 1966

  Note: the arguments are, in general, *not* checked for unreasonable
  values.

Parameters:

 IJOB
   IJOB is INTEGER
   Specifies what is to be done:
   = 1:  Compute NAB for the initial intervals.
   = 2:  Perform bisection iteration to find eigenvalues of T.
   = 3:  Perform bisection iteration to invert N(w), i.e.,
         to find a point which has a specified number of
         eigenvalues of T to its left.
   Other values will cause DLAEBZ to return with INFO=-1.

 NITMAX
   NITMAX is INTEGER
   The maximum number of "levels" of bisection to be
   performed, i.e., an interval of width W will not be made
   smaller than 2^(-NITMAX) * W.  If not all intervals
   have converged after NITMAX iterations, then INFO is set
   to the number of non-converged intervals.

 N
   N is INTEGER
   The dimension n of the tridiagonal matrix T.  It must be at least 1.

 MMAX
   MMAX is INTEGER
   The maximum number of intervals.  If more than MMAX intervals
   are generated, then DLAEBZ will quit with INFO=MMAX+1.

 MINP
   MINP is INTEGER
   The initial number of intervals.  It may not be greater than MMAX.

 NBMIN
   NBMIN is INTEGER
   The smallest number of intervals that should be processed
   using a vector loop.  If zero, then only the scalar loop will be used.

 ABSTOL
   ABSTOL is DOUBLE PRECISION
   The minimum (absolute) width of an interval.  When an
```

```
  interval is narrower than ABSTOL, or than RELTOL times the
  larger (in magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  This must be at least zero.

RELTOL
  RELTOL is DOUBLE PRECISION
  The minimum relative width of an interval.  When an interval
  is narrower than ABSTOL, or than RELTOL times the larger (in
  magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  Note: this should
  always be at least radix*machine epsilon.

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum absolute value of a "pivot" in the Sturm sequence loop.
  This must be at least  max |e(j)**2|*safe_min  and at
  least safe_min, where safe_min is at least
  the smallest number that can divide one without overflow.

D
  D is DOUBLE PRECISION array, dimension (N)
  The diagonal elements of the tridiagonal matrix T.

E
  E is DOUBLE PRECISION array, dimension (N)
  The offdiagonal elements of the tridiagonal matrix T in
  positions 1 through N-1.  E(N) is arbitrary.

E2
  E2 is DOUBLE PRECISION array, dimension (N)
  The squares of the offdiagonal elements of the tridiagonal
  matrix T.  E2(N) is ignored.

NVAL
  NVAL is INTEGER array, dimension (MINP)
  If IJOB=1 or 2, not referenced.
  If IJOB=3, the desired values of N(w).  The elements of NVAL
  will be reordered to correspond with the intervals in AB.
  Thus, NVAL(j) on output will not, in general be the same as
  NVAL(j) on input, but it will correspond with the interval
  (AB(j,1),AB(j,2)] on output.

AB
  AB is DOUBLE PRECISION array, dimension (MMAX,2)
  The endpoints of the intervals.  AB(j,1) is  a(j), the left
  endpoint of the j-th interval, and AB(j,2) is b(j), the
  right endpoint of the j-th interval.  The input intervals
  will, in general, be modified, split, and reordered by the calculation.

C
```

```
  C is DOUBLE PRECISION array, dimension (MMAX)
  If IJOB=1, ignored.
  If IJOB=2, workspace.
  If IJOB=3, then on input C(j) should be initialized to the
  first search point in the binary search.

MOUT
  MOUT is INTEGER
  If IJOB=1, the number of eigenvalues in the intervals.
  If IJOB=2 or 3, the number of intervals output.
  If IJOB=3, MOUT will equal MINP.

NAB
  NAB is INTEGER array, dimension (MMAX,2)
  If IJOB=1, then on output NAB(i,j) will be set to N(AB(i,j)).
  If IJOB=2, then on input, NAB(i,j) should be set.  It must
     satisfy the condition:
     N(AB(i,1)) <= NAB(i,1) <= NAB(i,2) <= N(AB(i,2)),
     which means that in interval i only eigenvalues
     NAB(i,1)+1,...,NAB(i,2) will be considered.  Usually,
     NAB(i,j)=N(AB(i,j)), from a previous call to DLAEBZ with IJOB=1.

  On output, NAB(i,j) will contain
  max(na(k),min(nb(k),N(AB(i,j)))), where k is the index of
  the input interval that the output interval
  (AB(j,1),AB(j,2)] came from, and na(k) and nb(k) are the
  the input values of NAB(k,1) and NAB(k,2).
  If IJOB=3, then on output, NAB(i,j) contains N(AB(i,j)),
  unless N(w) > NVAL(i) for all search points  w , in which
  case NAB(i,1) will not be modified, i.e., the output
  value will be the same as the input value (modulo
  reorderings -- see NVAL and AB), or unless N(w) < NVAL(i)
  for all search points  w , in which case NAB(i,2) will
  not be modified.  Normally, NAB should be set to some
  distinctive value(s) before DLAEBZ is called.

WORK
  WORK is DOUBLE PRECISION array, dimension (MMAX)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (MMAX)
  Workspace.

INFO
  INFO is INTEGER
  = 0:       All intervals converged.
  = 1--MMAX: The last INFO intervals did not converge.
  = MMAX+1:  More than MMAX intervals were generated.
```

```
Further Details:

   This routine is intended to be called only by other LAPACK
   routines, thus the interface is less user-friendly.  It is intended
   for two purposes:

   (a) finding eigenvalues.  In this case, DLAEBZ should have one or
       more initial intervals set up in AB, and DLAEBZ should be called
       with IJOB=1.  This sets up NAB, and also counts the eigenvalues.
       Intervals with no eigenvalues would usually be thrown out at
       this point.  Also, if not all the eigenvalues in an interval i
       are desired, NAB(i,1) can be increased or NAB(i,2) decreased.
       For example, set NAB(i,1)=NAB(i,2)-1 to get the largest
       eigenvalue.  DLAEBZ is then called with IJOB=2 and MMAX
       no smaller than the value of MOUT returned by the call with
       IJOB=1.  After this (IJOB=2) call, eigenvalues NAB(i,1)+1
       through NAB(i,2) are approximately AB(i,1) (or AB(i,2)) to the
       tolerance specified by ABSTOL and RELTOL.

   (b) finding an interval (a',b'] containing eigenvalues w(f),...,w(l).
       In this case, start with a Gershgorin interval  (a,b).  Set up
       AB to contain 2 search intervals, both initially (a,b).  One
       NVAL element should contain  f-1  and the other should contain l,
       while C should contain a and b, resp.  NAB(i,1) should be -1
       and NAB(i,2) should be N+1, to flag an error if the desired
       interval does not lie in (a,b).  DLAEBZ is then called with IJOB=3.
       On exit, if w(f-1) < w(f), then one of the intervals --
       j -- will have AB(j,1)=AB(j,2) and NAB(j,1)=NAB(j,2)=f-1, while
       if, to the specified tolerance, w(f-k)=...=w(f+r), k > 0 and r >= 0,
       then the interval will have  N(AB(j,1))=NAB(j,1)=f-k and
       N(AB(j,2))=NAB(j,2)=f+r.  The cases w(l) < w(l+1) and
       w(l-r)=...=w(l+k) are handled similarly.

====================================================================
dlaev2 examples
====================================================================

====================================================================
Man Page Details
====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dlaev2 (A, B, C, RT1, RT2, CS1, SN1)
           DLAEV2 computes the eigenvalues and eigenvectors of a 2-by-2
           symmetric/Hermitian matrix.

Function/Subroutine Documentation
   subroutine dlaev2 (double precision A, double precision B, double precision
       C, double precision RT1, double precision RT2, double precision CS1,
       double precision SN1)
       DLAEV2 computes the eigenvalues and eigenvectors of a 2-by-2
       symmetric/Hermitian matrix.

Purpose:
   DLAEV2 computes the eigendecomposition of a 2-by-2 symmetric matrix
      [  A   B  ]
      [  B   C  ].
   On return, RT1 is the eigenvalue of larger absolute value, RT2 is the
   eigenvalue of smaller absolute value, and (CS1,SN1) is the unit right
   eigenvector for RT1, giving the decomposition

      [ CS1  SN1 ] [  A   B  ] [ CS1 -SN1 ]  =  [ RT1  0  ]
      [-SN1  CS1 ] [  B   C  ] [ SN1  CS1 ]     [  0  RT2 ].

Parameters:

 A
   A is DOUBLE PRECISION
   The (1,1) element of the 2-by-2 matrix.

 B
   B is DOUBLE PRECISION
   The (1,2) element and the conjugate of the (2,1) element of
   the 2-by-2 matrix.

 C
   C is DOUBLE PRECISION
```

```
   The (2,2) element of the 2-by-2 matrix.

 RT1
   RT1 is DOUBLE PRECISION
   The eigenvalue of larger absolute value.

 RT2
   RT2 is DOUBLE PRECISION
   The eigenvalue of smaller absolute value.

 CS1
   CS1 is DOUBLE PRECISION

 SN1
   SN1 is DOUBLE PRECISION
   The vector (CS1, SN1) is a unit right eigenvector for RT1.

Further Details:
   RT1 is accurate to a few ulps barring over/underflow.

   RT2 may be inaccurate if there is massive cancellation in the
   determinant A*C-B*B; higher precision or correctly rounded or
   correctly truncated arithmetic would be needed to compute RT2
   accurately in all cases.

   CS1 and SN1 are accurate to a few ulps barring over/underflow.

   Overflow is possible only if RT1 is within a factor of 5 of overflow.
   Underflow is harmless if the input data is 0 or exceeds
   underflow_threshold / macheps.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlagts (JOB, N, A, B, C, D, IN, Y, TOL, INFO)
           DLAGTS solves the system of equations (T-I)x = y or (T-I)Tx =
           y,where T is a general tridiagonal matrix and  a scalar, using the
           LU factorization computed by slagtf.

Function/Subroutine Documentation
   subroutine dlagts (integer JOB, integer N, double precision, dimension( * )
       A, double precision, dimension( * ) B, double precision, dimension( * )
       C, double precision, dimension( * ) D, integer, dimension( * ) IN,
       double precision, dimension( * ) Y, double precision TOL, integer INFO)
       DLAGTS solves the system of equations (T-I)x = y or (T-I)Tx = y,where
       T is a general tridiagonal matrix and  a scalar, using the LU
       factorization computed by slagtf.

Purpose:
   DLAGTS may be used to solve one of the systems of equations

      (T - lambda*I)*x = y   or   (T - lambda*I)**T*x = y,

   where T is an n by n tridiagonal matrix, for x, following the
   factorization of (T - lambda*I) as

      (T - lambda*I) = P*L*U ,

   by routine DLAGTF. The choice of equation to be solved is
```

```
  controlled by the argument JOB, and in each case there is an option
  to perturb zero or very small diagonal elements of U, this option
  being intended for use in applications such as inverse iteration.

Parameters:

 JOB
   JOB is INTEGER
   Specifies the job to be performed by DLAGTS as follows:
   =  1: The equations  (T - lambda*I)x = y  are to be solved,
      but diagonal elements of U are not to be perturbed.
   = -1: The equations  (T - lambda*I)x = y  are to be solved
      and, if overflow would otherwise occur, the diagonal
      elements of U are to be perturbed. See argument TOL below.
   =  2: The equations  (T - lambda*I)**Tx = y  are to be solved,
      but diagonal elements of U are not to be perturbed.
   = -2: The equations  (T - lambda*I)**Tx = y  are to be solved
      and, if overflow would otherwise occur, the diagonal
      elements of U are to be perturbed. See argument TOL below.

 N
   N is INTEGER
   The order of the matrix T.

 A
   A is DOUBLE PRECISION array, dimension (N)
   On entry, A must contain the diagonal elements of U as
   returned from DLAGTF.

 B
   B is DOUBLE PRECISION array, dimension (N-1)
   On entry, B must contain the first super-diagonal elements of
   U as returned from DLAGTF.

 C
   C is DOUBLE PRECISION array, dimension (N-1)
   On entry, C must contain the sub-diagonal elements of L as
   returned from DLAGTF.

 D
   D is DOUBLE PRECISION array, dimension (N-2)
   On entry, D must contain the second super-diagonal elements
   of U as returned from DLAGTF.

 IN
   IN is INTEGER array, dimension (N)
   On entry, IN must contain details of the matrix P as returned from DLAGTF.

 Y
   Y is DOUBLE PRECISION array, dimension (N)
```

```
  On entry, the right hand side vector y.
  On exit, Y is overwritten by the solution vector x.

TOL
  TOL is DOUBLE PRECISION
  On entry, with  JOB .lt. 0, TOL should be the minimum
  perturbation to be made to very small diagonal elements of U.
  TOL should normally be chosen as about eps*norm(U), where eps
  is the relative machine precision, but if TOL is supplied as
  non-positive, then it is reset to eps*max( abs( u(i,j) ) ).
  If  JOB .gt. 0  then TOL is not referenced.

  On exit, TOL is changed as described above, only if TOL is
  non-positive on entry. Otherwise TOL is unchanged.

INFO
  INFO is INTEGER
  = 0   : successful exit
  .lt. 0: if INFO = -i, the i-th argument had an illegal value
  .gt. 0: overflow would occur when computing the INFO(th)
          element of the solution vector x. This can only occur
          when JOB is supplied as positive and either means
          that a diagonal element of U is very small, or that
          the elements of the right-hand side vector y are very large.
```

SYNOPSIS
   Functions/Subroutines
       logical function dlaisnan (DIN1, DIN2)
           DLAISNAN tests input for NaN by comparing two arguments for
           inequality.

Function/Subroutine Documentation
   logical function dlaisnan (double precision DIN1, double precision DIN2)
       DLAISNAN tests input for NaN by comparing two arguments for inequality.

Purpose:
   This routine is not for general use.  It exists solely to avoid
   over-optimization in DISNAN.

   DLAISNAN checks for NaNs by comparing its two arguments for
   inequality.  NaN is the only floating-point value where NaN != NaN
```

```
   returns .TRUE.  To check for NaNs, pass the same variable as both
   arguments.

   A compiler must assume that the two arguments are
   not the same variable, and the test will not be optimized away.
   Interprocedural or whole-program optimization may delete this
   test.  The ISNAN functions will be replaced by the correct
   Fortran 03 intrinsic once the intrinsic is widely available.

Parameters:

 DIN1
   DIN1 is DOUBLE PRECISION

 DIN2
   DIN2 is DOUBLE PRECISION
   Two numbers to compare for inequality.

subroutine dlamc1(Integer BETA, Integer T, Logical RND, Logical IEEE1)

Purpose:
   DLAMC1 determines the machine parameters given by BETA, T, RND, and IEEE1
```

```
BETA
  The base of the machine.

T
  The number of (BETA) digits in the mantissa

RND
  Specifies whether proper rounding (RND=.TRUE.) or chopping (RND=.FALSE.)
  occurs in addition. This may not be a reliable guide to the way in
  which the machine performs its arithmetic.

IEEE1
  Specifies whether rounding appears to be done in the
  'round to nearest' style.

subroutine dlamc2(Integer BETA, Integer T, Logical RND,
                  Double Precision EPS, Integer EMIN,
                  Double Precision RMIN, Integer EMAX,
                  Double Precision RMAX)
Purpose:
   DLAMC2 determines the machine parameters specified in its argument list.

 BETA
   The base of the machine

 T
   The number of (BETA) digits in the mantissa.

 RND
   Specifies whether proper rounding (RND=.TRUE.) or chopping
   (RND=.FALSE.) occurs in addition. This may not be a reliable guide
   to the way in which the machine performs its arithmetic.

 EPS
   The smallest positive number such that
      fl(1.0-EPS) .LT 1.0,
   where fl denotes the computed value.

 EMIN
   The minimum exponent before (gradual) underflow occurs.
```

```
RMIN
  The smallest normalized number for the machine, given by
     BASE**(EMIN-1)
  where BASE is the floating point value of BETA

EMAX
  The maximum exponent before overflow occurs.

RMAX
  The largest positive number for the machine, given by
     BASE**EMAX*(1-EPS)
  where BASE is the floating point value of BETA

SYNOPSIS
   Functions/Subroutines
       double precision function dlamch (CMACH)

   double precision function dlamch (character CMACH)
       DLAMCH
```

```
Purpose:
   DLAMCH determines double precision machine parameters.

Parameters:

 CMACH
   Specifies the value to be returned by DLAMCH:
   = 'E' or 'e',   DLAMCH := eps
   = 'S' or 's ,   DLAMCH := sfmin
   = 'B' or 'b',   DLAMCH := base
   = 'P' or 'p',   DLAMCH := eps*base
   = 'N' or 'n',   DLAMCH := t
   = 'R' or 'r',   DLAMCH := rnd
   = 'M' or 'm',   DLAMCH := emin
   = 'U' or 'u',   DLAMCH := rmin
   = 'L' or 'l',   DLAMCH := emax
   = 'O' or 'o',   DLAMCH := rmax
   where
   eps   = relative machine precision
   sfmin = safe minimum, such that 1/sfmin does not overflow
   base  = base of the machine
   prec  = eps*base
   t     = number of (base) digits in the mantissa
   rnd   = 1.0 when rounding occurs in addition, 0.0 otherwise
   emin  = minimum exponent before (gradual) underflow
   rmin  = underflow threshold - base**(emin-1)
   emax  = largest exponent before overflow
   rmax  = overflow threshold  - (base**emax)*(1-eps)

SYNOPSIS
   Functions/Subroutines
       integer function dlaneg (N, D, LLD, SIGMA, PIVMIN, R)
           DLANEG computes the Sturm count.
```

```
Function/Subroutine Documentation
   integer function dlaneg (integer N, double precision, dimension( * ) D,
       double precision, dimension( * ) LLD, double precision SIGMA, double
       precision PIVMIN, integer R)
       DLANEG computes the Sturm count.

Purpose:
   DLANEG computes the Sturm count, the number of negative pivots
   encountered while factoring tridiagonal T - sigma I = L D L^T.
   This implementation works directly on the factors without forming
   the tridiagonal matrix T.  The Sturm count is also the number of
   eigenvalues of T less than sigma.

   This routine is called from DLARRB.

   The current routine does not use the PIVMIN parameter but rather
   requires IEEE-754 propagation of Infinities and NaNs.  This
   routine also has no input range restrictions but does require
   default exception handling such that x/0 produces Inf when x is
   non-zero, and Inf/Inf produces NaN.  For more information, see:

   Marques, Riedy, and Voemel, "Benefits of IEEE-754 Features in
   Modern Symmetric Tridiagonal Eigensolvers," SIAM Journal on
   Scientific Computing, v28, n5, 2006.  DOI 10.1137/050641624
   (Tech report version in LAWN 172 with the same title.)

Parameters:

 N
   N is INTEGER
   The order of the matrix.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The N diagonal elements of the diagonal matrix D.

 LLD
   LLD is DOUBLE PRECISION array, dimension (N-1)
   The (N-1) elements L(i)*L(i)*D(i).

 SIGMA
   SIGMA is DOUBLE PRECISION
   Shift amount in T - sigma I = L D L^T.

 PIVMIN
   PIVMIN is DOUBLE PRECISION
   The minimum pivot in the Sturm sequence.  May be used
   when zero pivots are encountered on non-IEEE-754 architectures.

 R
```

```
R is INTEGER
The twist index for the twisted factorization that is used
for the negcount.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       double precision function dlanst (NORM, N, D, E)
           DLANST returns the value of the 1-norm, or the Frobenius norm, or
           the infinity norm, or the element of largest absolute value of a
           real symmetric tridiagonal matrix.

Function/Subroutine Documentation
   double precision function dlanst (character NORM, integer N, double
       precision, dimension( * ) D, double precision, dimension( * ) E)
       DLANST returns the value of the 1-norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a real
       symmetric tridiagonal matrix.

Purpose:
   DLANST  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   real symmetric tridiagonal matrix A.

 Returns:

   DLANST

        DLANST = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                 (
                 ( norm1(A),         NORM = '1', 'O' or 'o'
                 (
                 ( normI(A),         NORM = 'I' or 'i'
                 (
                 ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in DLANST as described above.

 N
   N is INTEGER
   The order of the matrix A.  N >= 0.  When N = 0, DLANST is set to zero.

 D
   D is DOUBLE PRECISION array, dimension (N)
```

```
  The diagonal elements of A.

 E
  E is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) sub-diagonal or super-diagonal elements of A.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlarnv (IDIST, ISEED, N, X)
           DLARNV returns a vector of random numbers from a uniform or normal
           distribution.

Function/Subroutine Documentation
   subroutine dlarnv (integer IDIST, integer, dimension( 4 ) ISEED, integer N,
       double precision, dimension( * ) X)
       DLARNV returns a vector of random numbers from a uniform or normal
       distribution.

Purpose:
   DLARNV returns a vector of n random real numbers from a uniform or
   normal distribution.

Parameters:

 IDIST
   IDIST is INTEGER
   Specifies the distribution of the random numbers:
   = 1:  uniform (0,1)
   = 2:  uniform (-1,1)
   = 3:  normal (0,1)

 ISEED
   ISEED is INTEGER array, dimension (4)
   On entry, the seed of the random number generator; the array
   elements must be between 0 and 4095, and ISEED(4) must be odd.
   On exit, the seed is updated.

 N
   N is INTEGER
   The number of random numbers to be generated.

 X
   X is DOUBLE PRECISION array, dimension (N)
   The generated random numbers.

Further Details:

   This routine calls the auxiliary routine DLARUV to generate random
   real numbers from a uniform (0,1) distribution, in batches of up to
   128 using vectorisable code. The Box-Muller method is used to
   transform numbers from a uniform to a normal distribution.

SYNOPSIS
   Functions/Subroutines
       subroutine dlarra (N, D, E, E2, SPLTOL, TNRM, NSPLIT, ISPLIT, INFO)
           DLARRA computes the splitting points with the specified threshold.

Function/Subroutine Documentation
   subroutine dlarra (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision, dimension( * ) E2,
       double precision SPLTOL, double precision TNRM, integer NSPLIT,
       integer, dimension( * ) ISPLIT, integer INFO)
       DLARRA computes the splitting points with the specified threshold.

Purpose:
   Compute the splitting points with threshold SPLTOL.
   DLARRA sets any "small" off-diagonal elements to zero.

Parameters:

 N
   N is INTEGER
   The order of the matrix. N > 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry, the N diagonal elements of the tridiagonal matrix T.
```

```
E
  E is DOUBLE PRECISION array, dimension (N)
  On entry, the first (N-1) entries contain the subdiagonal
  elements of the tridiagonal matrix T; E(N) need not be set.
  On exit, the entries E( ISPLIT( I ) ), 1 <= I <= NSPLIT,
  are set to zero, the other entries of E are untouched.

E2
  E2 is DOUBLE PRECISION array, dimension (N)
  On entry, the first (N-1) entries contain the SQUARES of the
  subdiagonal elements of the tridiagonal matrix T;
  E2(N) need not be set.
  On exit, the entries E2( ISPLIT( I ) ),
  1 <= I <= NSPLIT, have been set to zero

SPLTOL
  SPLTOL is DOUBLE PRECISION
  The threshold for splitting. Two criteria can be used:
  SPLTOL<0 : criterion based on absolute off-diagonal value
  SPLTOL>0 : criterion that preserves relative accuracy

TNRM
  TNRM is DOUBLE PRECISION
  The norm of the matrix.

NSPLIT
  NSPLIT is INTEGER
  The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT
  ISPLIT is INTEGER array, dimension (N)
  The splitting points, at which T breaks up into blocks.
  The first block consists of rows/columns 1 to ISPLIT(1),
  the second of rows/columns ISPLIT(1)+1 through ISPLIT(2),
  etc., and the NSPLIT-th consists of rows/columns
  ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

INFO
  INFO is INTEGER
  = 0:  successful exit
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlarrb (N, D, LLD, IFIRST, ILAST, RTOL1, RTOL2, OFFSET, W,
```

```
          WGAP, WERR, WORK, IWORK, PIVMIN, SPDIAM, TWIST, INFO)
          DLARRB provides limited bisection to locate eigenvalues for more
          accuracy.

Function/Subroutine Documentation
   subroutine dlarrb (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) LLD, integer IFIRST, integer ILAST, double
       precision RTOL1, double precision RTOL2, integer OFFSET, double
       precision, dimension( * ) W, double precision, dimension( * ) WGAP,
       double precision, dimension( * ) WERR, double precision, dimension( * )
       WORK, integer, dimension( * ) IWORK, double precision PIVMIN, double
       precision SPDIAM, integer TWIST, integer INFO)
       DLARRB provides limited bisection to locate eigenvalues for more
       accuracy.

Purpose:
   Given the relatively robust representation(RRR) L D L^T, DLARRB
   does "limited" bisection to refine the eigenvalues of L D L^T,
   W( IFIRST-OFFSET ) through W( ILAST-OFFSET ), to more accuracy. Initial
   guesses for these eigenvalues are input in W, the corresponding estimate
   of the error in these guesses and their gaps are input in WERR
   and WGAP, respectively. During bisection, intervals
   [left, right] are maintained by storing their mid-points and
   semi-widths in the arrays W and WERR respectively.

Parameters:

 N
   N is INTEGER
   The order of the matrix.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The N diagonal elements of the diagonal matrix D.

 LLD
   LLD is DOUBLE PRECISION array, dimension (N-1)
   The (N-1) elements L(i)*L(i)*D(i).

 IFIRST
   IFIRST is INTEGER
   The index of the first eigenvalue to be computed.

 ILAST
   ILAST is INTEGER
   The index of the last eigenvalue to be computed.

 RTOL1
   RTOL1 is DOUBLE PRECISION
```

```
RTOL2
  RTOL2 is DOUBLE PRECISION
  Tolerance for the convergence of the bisection intervals.
  An interval [LEFT,RIGHT] has converged if
  RIGHT-LEFT.LT.MAX( RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|) )
  where GAP is the (estimated) distance to the nearest eigenvalue.

OFFSET
  OFFSET is INTEGER
  Offset for the arrays W, WGAP and WERR, i.e., the IFIRST-OFFSET
  through ILAST-OFFSET elements of these arrays are to be used.

W
  W is DOUBLE PRECISION array, dimension (N)
  On input, W( IFIRST-OFFSET ) through W( ILAST-OFFSET ) are
  estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST.
  On output, these estimates are refined.

WGAP
  WGAP is DOUBLE PRECISION array, dimension (N-1)
  On input, the (estimated) gaps between consecutive
  eigenvalues of L D L^T, i.e., WGAP(I-OFFSET) is the gap between
  eigenvalues I and I+1. Note that if IFIRST.EQ.ILAST
  then WGAP(IFIRST-OFFSET) must be set to ZERO.
  On output, these gaps are refined.

WERR
  WERR is DOUBLE PRECISION array, dimension (N)
  On input, WERR( IFIRST-OFFSET ) through WERR( ILAST-OFFSET ) are
  the errors in the estimates of the corresponding elements in W.
  On output, these errors are refined.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (2*N)
  Workspace.

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot in the Sturm sequence.

SPDIAM
  SPDIAM is DOUBLE PRECISION
  The spectral diameter of the matrix.

TWIST
  TWIST is INTEGER
```

```
  The twist index for the twisted factorization that is used
  for the negcount.
  TWIST = N: Compute negcount from L D L^T - LAMBDA I = L+ D+ L+^T
  TWIST = 1: Compute negcount from L D L^T - LAMBDA I = U- D- U-^T
  TWIST = R: Compute negcount from L D L^T - LAMBDA I = N(r) D(r) N(r)

INFO
  INFO is INTEGER
  Error flag.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlarrc (JOBT, N, VL, VU, D, E, PIVMIN, EIGCNT, LCNT, RCNT,
           INFO)
           DLARRC computes the number of eigenvalues of the symmetric
           tridiagonal matrix.

Function/Subroutine Documentation
   subroutine dlarrc (character JOBT, integer N, double precision VL, double
       precision VU, double precision, dimension( * ) D, double precision,
       dimension( * ) E, double precision PIVMIN, integer EIGCNT, integer
       LCNT, integer RCNT, integer INFO)
       DLARRC computes the number of eigenvalues of the symmetric tridiagonal
       matrix.

Purpose:
   Find the number of eigenvalues of the symmetric tridiagonal matrix T
   that are in the interval (VL,VU] if JOBT = 'T', and of L D L^T
   if JOBT = 'L'.

Parameters:

 JOBT
   JOBT is CHARACTER*1
   = 'T':  Compute Sturm count for matrix T.
   = 'L':  Compute Sturm count for matrix L D L^T.

 N
   N is INTEGER
   The order of the matrix. N > 0.

 VL
   VL is DOUBLE PRECISION

 VU
   VU is DOUBLE PRECISION
   The lower and upper bounds for the eigenvalues.

 D
   D is DOUBLE PRECISION array, dimension (N)
   JOBT = 'T': The N diagonal elements of the tridiagonal matrix T.
   JOBT = 'L': The N diagonal elements of the diagonal matrix D.
```

```
E
  E is DOUBLE PRECISION array, dimension (N)
  JOBT = 'T': The N-1 offdiagonal elements of the matrix T.
  JOBT = 'L': The N-1 offdiagonal elements of the matrix L.

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot in the Sturm sequence for T.

EIGCNT
  EIGCNT is INTEGER
  The number of eigenvalues of the symmetric tridiagonal matrix T
  that are in the interval (VL,VU]

LCNT
  LCNT is INTEGER

RCNT
  RCNT is INTEGER
  The left and right negcounts of the interval.

INFO
  INFO is INTEGER
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlarrd (RANGE, ORDER, N, VL, VU, IL, IU, GERS, RELTOL, D, E,
           E2, PIVMIN, NSPLIT, ISPLIT, M, W, WERR, WL, WU, IBLOCK, INDEXW,
           WORK, IWORK, INFO)
           DLARRD computes the eigenvalues of a symmetric tridiagonal matrix
           to suitable accuracy.

Function/Subroutine Documentation
   subroutine dlarrd (character RANGE, character ORDER, integer N, double
       precision VL, double precision VU, integer IL, integer IU, double
       precision, dimension( * ) GERS, double precision RELTOL, double
       precision, dimension( * ) D, double precision, dimension( * ) E, double
       precision, dimension( * ) E2, double precision PIVMIN, integer NSPLIT,
       integer, dimension( * ) ISPLIT, integer M, double precision, dimension(
       * ) W, double precision, dimension( * ) WERR, double precision WL,
       double precision WU, integer, dimension( * ) IBLOCK, integer,
       dimension( * ) INDEXW, double precision, dimension( * ) WORK, integer,
       dimension( * ) IWORK, integer INFO)
       DLARRD computes the eigenvalues of a symmetric tridiagonal matrix to
       suitable accuracy.

Purpose:
   DLARRD computes the eigenvalues of a symmetric tridiagonal
   matrix T to suitable accuracy. This is an auxiliary code to be
   called from DSTEMR.
   The user may ask for all eigenvalues, all eigenvalues
   in the half-open interval (VL, VU], or the IL-th through IU-th
   eigenvalues.

   To avoid overflow, the matrix must be scaled so that its
   largest element is no greater than
   overflow**(1/2) * underflow**(1/4)
   in absolute value, and for greatest
   accuracy, it should not be much smaller than that.

Parameters:

 RANGE
   RANGE is CHARACTER*1
   = 'A': ("All")   all eigenvalues will be found.
   = 'V': ("Value") all eigenvalues in the half-open interval
          (VL, VU] will be found.
   = 'I': ("Index") the IL-th through IU-th eigenvalues (of the
          entire matrix) will be found.

 ORDER
   ORDER is CHARACTER*1
   = 'B': ("By Block") the eigenvalues will be grouped by
        split-off block (see IBLOCK, ISPLIT) and
```

```
        ordered from smallest to largest within the block.
  = 'E': ("Entire matrix")
        the eigenvalues for the entire matrix
        will be ordered from smallest to largest.

N
  N is INTEGER
  The order of the tridiagonal matrix T.  N >= 0.

VL
  VL is DOUBLE PRECISION

VU
  VU is DOUBLE PRECISION
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues.  Eigenvalues less than or equal
  to VL, or greater than VU, will not be returned.  VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

GERS
  GERS is DOUBLE PRECISION array, dimension (2*N)
  The N Gerschgorin intervals (the i-th Gerschgorin interval
  is (GERS(2*i-1), GERS(2*i)).

RELTOL
  RELTOL is DOUBLE PRECISION
  The minimum relative width of an interval.  When an interval
  is narrower than RELTOL times the larger (in
  magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  Note: this should
  always be at least radix*machine epsilon.

D
  D is DOUBLE PRECISION array, dimension (N)
  The n diagonal elements of the tridiagonal matrix T.

E
  E is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) off-diagonal elements of the tridiagonal matrix T.
```

```
E2
  E2 is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot allowed in the Sturm sequence for T.

NSPLIT
  NSPLIT is INTEGER
  The number of diagonal blocks in the matrix T.
  1 <= NSPLIT <= N.

ISPLIT
  ISPLIT is INTEGER array, dimension (N)
  The splitting points, at which T breaks up into submatrices.
  The first submatrix consists of rows/columns 1 to ISPLIT(1),
  the second of rows/columns ISPLIT(1)+1 through ISPLIT(2),
  etc., and the NSPLIT-th consists of rows/columns
  ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.
  (Only the first NSPLIT elements will actually be used, but
  since the user cannot know a priori what value NSPLIT will
  have, N words must be reserved for ISPLIT.)

M
  M is INTEGER
  The actual number of eigenvalues found. 0 <= M <= N.
  (See also the description of INFO=2,3.)

W
  W is DOUBLE PRECISION array, dimension (N)
  On exit, the first M elements of W will contain the
  eigenvalue approximations. DLARRD computes an interval
  I_j = (a_j, b_j] that includes eigenvalue j. The eigenvalue
  approximation is given as the interval midpoint
  W(j)= ( a_j + b_j)/2. The corresponding error is bounded by
  WERR(j) = abs( a_j - b_j)/2

WERR
  WERR is DOUBLE PRECISION array, dimension (N)
  The error bound on the corresponding eigenvalue approximation in W.

WL
  WL is DOUBLE PRECISION

WU
  WU is DOUBLE PRECISION
  The interval (WL, WU] contains all the wanted eigenvalues.
  If RANGE='V', then WL=VL and WU=VU.
  If RANGE='A', then WL and WU are the global Gerschgorin bounds
```

```
        on the spectrum.
  If RANGE='I', then WL and WU are computed by DLAEBZ from the
        index range specified.

 IBLOCK
  IBLOCK is INTEGER array, dimension (N)
  At each row/column j where E(j) is zero or small, the
  matrix T is considered to split into a block diagonal
  matrix.  On exit, if INFO = 0, IBLOCK(i) specifies to which
  block (from 1 to the number of blocks) the eigenvalue W(i)
  belongs.  (DLARRD may use the remaining N-M elements as workspace.)

 INDEXW
  INDEXW is INTEGER array, dimension (N)
  The indices of the eigenvalues within each block (submatrix);
  for example, INDEXW(i)= j and IBLOCK(i)=k imply that the
  i-th eigenvalue W(i) is the j-th eigenvalue in block k.

 WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)

 IWORK
  IWORK is INTEGER array, dimension (3*N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  some or all of the eigenvalues failed to converge or
        were not computed:
  =1 or 3: Bisection failed to converge for some
        eigenvalues; these eigenvalues are flagged by a
        negative block number.  The effect is that the
        eigenvalues may not be as accurate as the
        absolute and relative tolerances.  This is
        generally caused by unexpectedly inaccurate arithmetic.
  =2 or 3: RANGE='I' only: Not all of the eigenvalues
        IL:IU were found.
        Effect: M < IU+1-IL
        Cause:  non-monotonic arithmetic, causing the
           Sturm sequence to be non-monotonic.
        Cure:   recalculate, using RANGE='A', and pick
           out eigenvalues IL:IU.  In some cases,
           increasing the PARAMETER "FUDGE" may make things work.
  = 4:    RANGE='I', and the Gershgorin interval
        initially used was too small.  No eigenvalues were computed.
        Probable cause: your machine has sloppy floating-point arithmetic.
        Cure: Increase the PARAMETER "FUDGE", recompile, and try again.

Internal Parameters:
```

```
 FUDGE   DOUBLE PRECISION, default = 2
   A "fudge factor" to widen the Gershgorin intervals.  Ideally,
   a value of 1 should work, but on machines with sloppy
   arithmetic, this needs to be larger.  The default for
   publicly released versions should be large enough to handle
   the worst machine around.  Note that this has no effect
   on accuracy of the solution.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlarre (RANGE, N, VL, VU, IL, IU, D, E, E2, RTOL1, RTOL2,
           SPLTOL, NSPLIT, ISPLIT, M, W, WERR, WGAP, IBLOCK, INDEXW, GERS,
           PIVMIN, WORK, IWORK, INFO)
           DLARRE given the tridiagonal matrix T, sets small off-diagonal
           elements to zero and for each unreduced block Ti, finds base
           representations and eigenvalues.

Function/Subroutine Documentation
   subroutine dlarre (character RANGE, integer N, double precision VL, double
       precision VU, integer IL, integer IU, double precision, dimension( * )
       D, double precision, dimension( * ) E, double precision, dimension( * )
       E2, double precision RTOL1, double precision RTOL2, double precision
       SPLTOL, integer NSPLIT, integer, dimension( * ) ISPLIT, integer M,
       double precision, dimension( * ) W, double precision, dimension( * )
       WERR, double precision, dimension( * ) WGAP, integer, dimension( * )
       IBLOCK, integer, dimension( * ) INDEXW, double precision, dimension( *
       ) GERS, double precision PIVMIN, double precision, dimension( * ) WORK,
       integer, dimension( * ) IWORK, integer INFO)
       DLARRE given the tridiagonal matrix T, sets small off-diagonal elements
       to zero and for each unreduced block Ti, finds base representations and
       eigenvalues.

Purpose:
   To find the desired eigenvalues of a given real symmetric
   tridiagonal matrix T, DLARRE sets any "small" off-diagonal
   elements to zero, and for each unreduced block T_i, it finds
   (a) a suitable shift at one end of the block's spectrum,
```

```
   (b) the base representation, T_i - sigma_i I = L_i D_i L_i^T, and
   (c) eigenvalues of each L_i D_i L_i^T.
   The representations and eigenvalues found are then used by
   DSTEMR to compute the eigenvectors of T.
   The accuracy varies depending on whether bisection is used to
   find a few eigenvalues or the dqds algorithm (subroutine DLASQ2) to
   conpute all and then discard any unwanted one.
   As an added benefit, DLARRE also outputs the n
   Gerschgorin intervals for the matrices L_i D_i L_i^T.

Parameters:

 RANGE
   RANGE is CHARACTER*1
   = 'A': ("All")   all eigenvalues will be found.
   = 'V': ("Value") all eigenvalues in the half-open interval
          (VL, VU] will be found.
   = 'I': ("Index") the IL-th through IU-th eigenvalues (of the
          entire matrix) will be found.

 N
   N is INTEGER
   The order of the matrix. N > 0.

 VL
   VL is DOUBLE PRECISION

 VU
   VU is DOUBLE PRECISION
   If RANGE='V', the lower and upper bounds for the eigenvalues.
   Eigenvalues less than or equal to VL, or greater than VU,
   will not be returned.  VL < VU.
   If RANGE='I' or ='A', DLARRE computes bounds on the desired
   part of the spectrum.

 IL
   IL is INTEGER

 IU
   IU is INTEGER
   If RANGE='I', the indices (in ascending order) of the
   smallest and largest eigenvalues to be returned.
   1 <= IL <= IU <= N.

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry, the N diagonal elements of the tridiagonal matrix T.
   On exit, the N diagonal elements of the diagonal matrices D_i.

 E
```

```
  E is DOUBLE PRECISION array, dimension (N)
  On entry, the first (N-1) entries contain the subdiagonal
  elements of the tridiagonal matrix T; E(N) need not be set.
  On exit, E contains the subdiagonal elements of the unit
  bidiagonal matrices L_i. The entries E( ISPLIT( I ) ),
  1 <= I <= NSPLIT, contain the base points sigma_i on output.

E2
  E2 is DOUBLE PRECISION array, dimension (N)
  On entry, the first (N-1) entries contain the SQUARES of the
  subdiagonal elements of the tridiagonal matrix T;
  E2(N) need not be set.
  On exit, the entries E2( ISPLIT( I ) ),
  1 <= I <= NSPLIT, have been set to zero

RTOL1
  RTOL1 is DOUBLE PRECISION

RTOL2
  RTOL2 is DOUBLE PRECISION
  Parameters for bisection.
  An interval [LEFT,RIGHT] has converged if
  RIGHT-LEFT.LT.MAX( RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|) )

SPLTOL
  SPLTOL is DOUBLE PRECISION
  The threshold for splitting.

NSPLIT
  NSPLIT is INTEGER
  The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT
  ISPLIT is INTEGER array, dimension (N)
  The splitting points, at which T breaks up into blocks.
  The first block consists of rows/columns 1 to ISPLIT(1),
  the second of rows/columns ISPLIT(1)+1 through ISPLIT(2),
  etc., and the NSPLIT-th consists of rows/columns
  ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

M
  M is INTEGER
  The total number of eigenvalues (of all L_i D_i L_i^T) found.

W
  W is DOUBLE PRECISION array, dimension (N)
  The first M elements contain the eigenvalues. The
  eigenvalues of each of the blocks, L_i D_i L_i^T, are
  sorted in ascending order ( DLARRE may use the
  remaining N-M elements as workspace).
```

```
WERR
  WERR is DOUBLE PRECISION array, dimension (N)
  The error bound on the corresponding eigenvalue in W.

WGAP
  WGAP is DOUBLE PRECISION array, dimension (N)
  The separation from the right neighbor eigenvalue in W.
  The gap is only with respect to the eigenvalues of the same block
  as each block has its own representation tree.
  Exception: at the right end of a block we store the left gap

IBLOCK
  IBLOCK is INTEGER array, dimension (N)
  The indices of the blocks (submatrices) associated with the
  corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue
  W(i) belongs to the first block from the top, =2 if W(i)
  belongs to the second block, etc.

INDEXW
  INDEXW is INTEGER array, dimension (N)
  The indices of the eigenvalues within each block (submatrix);
  for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the
  i-th eigenvalue W(i) is the 10-th eigenvalue in block 2

GERS
  GERS is DOUBLE PRECISION array, dimension (2*N)
  The N Gerschgorin intervals (the i-th Gerschgorin interval
  is (GERS(2*i-1), GERS(2*i)).

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot in the Sturm sequence for T.

WORK
  WORK is DOUBLE PRECISION array, dimension (6*N)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (5*N)
  Workspace.

INFO
  INFO is INTEGER
  = 0:  successful exit
  > 0:  A problem occured in DLARRE.
  < 0:  One of the called subroutines signaled an internal problem.
        Needs inspection of the corresponding parameter IINFO
        for further information.
```

```
   =-1:  Problem in DLARRD.
   = 2:  No base representation could be found in MAXTRY iterations.
         Increasing MAXTRY and recompilation might be a remedy.
   =-3:  Problem in DLARRB when computing the refined root
         representation for DLASQ2.
   =-4:  Problem in DLARRB when preforming bisection on the
         desired part of the spectrum.
   =-5:  Problem in DLASQ2.
   =-6:  Problem in DLASQ2.

Further Details:

   The base representations are required to suffer very little
   element growth and consequently define all their eigenvalues to
   high relative accuracy.

SYNOPSIS
   Functions/Subroutines
       subroutine dlarrf (N, D, L, LD, CLSTRT, CLEND, W, WGAP, WERR, SPDIAM,
           CLGAPL, CLGAPR, PIVMIN, SIGMA, DPLUS, LPLUS, WORK, INFO)
           DLARRF finds a new relatively robust representation such that at
           least one of the eigenvalues is relatively isolated.

Function/Subroutine Documentation
   subroutine dlarrf (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) L, double precision, dimension( * ) LD,
       integer CLSTRT, integer CLEND, double precision, dimension( * ) W,
       double precision, dimension( * ) WGAP, double precision, dimension( * )
       WERR, double precision SPDIAM, double precision CLGAPL, double
       precision CLGAPR, double precision PIVMIN, double precision SIGMA,
       double precision, dimension( * ) DPLUS, double precision, dimension( *
       ) LPLUS, double precision, dimension( * ) WORK, integer INFO)
```

```
      DLARRF finds a new relatively robust representation such that at least
      one of the eigenvalues is relatively isolated.

Purpose:
   Given the initial representation L D L^T and its cluster of close
   eigenvalues (in a relative measure), W( CLSTRT ), W( CLSTRT+1 ), ...
   W( CLEND ), DLARRF finds a new relatively robust representation
   L D L^T - SIGMA I = L(+) D(+) L(+)^T such that at least one of the
   eigenvalues of L(+) D(+) L(+)^T is relatively isolated.

Parameters:

 N
   N is INTEGER
   The order of the matrix (subblock, if the matrix splitted).

 D
   D is DOUBLE PRECISION array, dimension (N)
   The N diagonal elements of the diagonal matrix D.

 L
   L is DOUBLE PRECISION array, dimension (N-1)
   The (N-1) subdiagonal elements of the unit bidiagonal matrix L.

 LD
   LD is DOUBLE PRECISION array, dimension (N-1)
   The (N-1) elements L(i)*D(i).

 CLSTRT
   CLSTRT is INTEGER
   The index of the first eigenvalue in the cluster.

 CLEND
   CLEND is INTEGER
   The index of the last eigenvalue in the cluster.

 W
   W is DOUBLE PRECISION array, dimension
   dimension is >=  (CLEND-CLSTRT+1)
   The eigenvalue APPROXIMATIONS of L D L^T in ascending order.
   W( CLSTRT ) through W( CLEND ) form the cluster of relatively
   close eigenalues.

 WGAP
   WGAP is DOUBLE PRECISION array, dimension
   dimension is >=  (CLEND-CLSTRT+1)
   The separation from the right neighbor eigenvalue in W.

 WERR
   WERR is DOUBLE PRECISION array, dimension
```

```
  dimension is  >=  (CLEND-CLSTRT+1)
  WERR contain the semiwidth of the uncertainty
  interval of the corresponding eigenvalue APPROXIMATION in W

SPDIAM
  SPDIAM is DOUBLE PRECISION
  estimate of the spectral diameter obtained from the
  Gerschgorin intervals

CLGAPL
  CLGAPL is DOUBLE PRECISION

CLGAPR
  CLGAPR is DOUBLE PRECISION
  absolute gap on each end of the cluster.
  Set by the calling routine to protect against shifts too close
  to eigenvalues outside the cluster.

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot allowed in the Sturm sequence.

SIGMA
  SIGMA is DOUBLE PRECISION
  The shift used to form L(+) D(+) L(+)^T.

DPLUS
  DPLUS is DOUBLE PRECISION array, dimension (N)
  The N diagonal elements of the diagonal matrix D(+).

LPLUS
  LPLUS is DOUBLE PRECISION array, dimension (N-1)
  The first (N-1) elements of LPLUS contain the subdiagonal
  elements of the unit bidiagonal matrix L(+).

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)
  Workspace.

INFO
  INFO is INTEGER
  Signals processing OK (=0) or failure (=1)
```

*     Note that we cannot guarantee that for any of the shifts tried,
*     the factorization has a small or even moderate element growth.
*     There could be Ritz values at both ends of the cluster and despite
*     backing off, there are examples where all factorizations tried
*     (in IEEE mode, allowing zero pivots & infinities) have INFINITE
*     element growth.
*     For this reason, we should use PIVMIN in this subroutine so that at
*     least the L D L^T factorization exists. It can be checked afterwards
*     whether the element growth caused bad residuals/orthogonality.

*     Decide whether the code should accept the best among all
*     representations despite large element growth or signal INFO=1
*     Setting NOFAIL to .FALSE. for quick fix for bug 113

SYNOPSIS
   Functions/Subroutines
       subroutine dlarrj (N, D, E2, IFIRST, ILAST, RTOL, OFFSET, W, WERR,
           WORK, IWORK, PIVMIN, SPDIAM, INFO)
           DLARRJ performs refinement of the initial estimates of the
           eigenvalues of the matrix T.

Function/Subroutine Documentation
   subroutine dlarrj (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) E2, integer IFIRST, integer ILAST, double
       precision RTOL, integer OFFSET, double precision, dimension( * ) W,
       double precision, dimension( * ) WERR, double precision, dimension( * )
       WORK, integer, dimension( * ) IWORK, double precision PIVMIN, double
       precision SPDIAM, integer INFO)
       DLARRJ performs refinement of the initial estimates of the eigenvalues
       of the matrix T.
```

```
Purpose:
   Given the initial eigenvalue approximations of T, DLARRJ
   does  bisection to refine the eigenvalues of T,
   W( IFIRST-OFFSET ) through W( ILAST-OFFSET ), to more accuracy. Initial
   guesses for these eigenvalues are input in W, the corresponding estimate
   of the error in these guesses in WERR. During bisection, intervals
   [left, right] are maintained by storing their mid-points and
   semi-widths in the arrays W and WERR respectively.

Parameters:

 N
   N is INTEGER
   The order of the matrix.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The N diagonal elements of T.

 E2
   E2 is DOUBLE PRECISION array, dimension (N-1)
   The Squares of the (N-1) subdiagonal elements of T.

 IFIRST
   IFIRST is INTEGER
   The index of the first eigenvalue to be computed.

 ILAST
   ILAST is INTEGER
   The index of the last eigenvalue to be computed.

 RTOL
   RTOL is DOUBLE PRECISION
   Tolerance for the convergence of the bisection intervals.
   An interval [LEFT,RIGHT] has converged if
   RIGHT-LEFT.LT.RTOL*MAX(|LEFT|,|RIGHT|).

 OFFSET
   OFFSET is INTEGER
   Offset for the arrays W and WERR, i.e., the IFIRST-OFFSET
   through ILAST-OFFSET elements of these arrays are to be used.

 W
   W is DOUBLE PRECISION array, dimension (N)
   On input, W( IFIRST-OFFSET ) through W( ILAST-OFFSET ) are
   estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST.
   On output, these estimates are refined.

 WERR
```

```
  WERR is DOUBLE PRECISION array, dimension (N)
  On input, WERR( IFIRST-OFFSET ) through WERR( ILAST-OFFSET ) are
  the errors in the estimates of the corresponding elements in W.
  On output, these errors are refined.

WORK
  WORK is DOUBLE PRECISION array, dimension (2*N)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (2*N)
  Workspace.

PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot in the Sturm sequence for T.

SPDIAM
  SPDIAM is DOUBLE PRECISION
  The spectral diameter of T.

INFO
  INFO is INTEGER
  Error flag.

SYNOPSIS
   Functions/Subroutines
       subroutine dlarrk (N, IW, GL, GU, D, E2, PIVMIN, RELTOL, W, WERR, INFO)
           DLARRK computes one eigenvalue of a symmetric tridiagonal matrix T
           to suitable accuracy.

Function/Subroutine Documentation
   subroutine dlarrk (integer N, integer IW, double precision GL, double
       precision GU, double precision, dimension( * ) D, double precision,
       dimension( * ) E2, double precision PIVMIN, double precision RELTOL,
       double precision W, double precision WERR, integer INFO)
       DLARRK computes one eigenvalue of a symmetric tridiagonal matrix T to
       suitable accuracy.

Purpose:
   DLARRK computes one eigenvalue of a symmetric tridiagonal
   matrix T to suitable accuracy. This is an auxiliary code to be
   called from DSTEMR.

   To avoid overflow, the matrix must be scaled so that its
   largest element is no greater than
      overflow**(1/2) * underflow**(1/4)
   in absolute value, and for greatest
   accuracy, it should not be much smaller than that.

Parameters:

 N
   N is INTEGER
   The order of the tridiagonal matrix T.  N >= 0.

 IW
   IW is INTEGER
   The index of the eigenvalues to be returned.

 GL
   GL is DOUBLE PRECISION

 GU
   GU is DOUBLE PRECISION
   An upper and a lower bound on the eigenvalue.

 D
   D is DOUBLE PRECISION array, dimension (N)
```

```
  The n diagonal elements of the tridiagonal matrix T.

 E2
  E2 is DOUBLE PRECISION array, dimension (N-1)
  The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

 PIVMIN
  PIVMIN is DOUBLE PRECISION
  The minimum pivot allowed in the Sturm sequence for T.

 RELTOL
  RELTOL is DOUBLE PRECISION
  The minimum relative width of an interval.  When an interval
  is narrower than RELTOL times the larger (in
  magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  Note: this should
  always be at least radix*machine epsilon.

 W
  W is DOUBLE PRECISION

 WERR
  WERR is DOUBLE PRECISION
  The error bound on the corresponding eigenvalue approximation in W.

 INFO
  INFO is INTEGER
  = 0:       Eigenvalue converged
  = -1:      Eigenvalue did NOT converge

Internal Parameters:

 FUDGE   DOUBLE PRECISION, default = 2
  A "fudge factor" to widen the Gershgorin intervals.
```

   Functions/Subroutines
       subroutine dlarrr (N, D, E, INFO)
           DLARRR performs tests to decide whether the symmetric tridiagonal
           matrix T warrants expensive computations which guarantee high
```

```
          relative accuracy in the eigenvalues.

Function/Subroutine Documentation
   subroutine dlarrr (integer N, double precision, dimension( * ) D, double
       precision, dimension( * ) E, integer INFO)
       DLARRR performs tests to decide whether the symmetric tridiagonal
       matrix T warrants expensive computations which guarantee high relative
       accuracy in the eigenvalues.

Purpose:
   Perform tests to decide whether the symmetric tridiagonal matrix T
   warrants expensive computations which guarantee high relative accuracy
   in the eigenvalues.

Parameters:

 N
   N is INTEGER
   The order of the matrix. N > 0.

 D
   D is DOUBLE PRECISION array, dimension (N)
   The N diagonal elements of the tridiagonal matrix T.

 E
   E is DOUBLE PRECISION array, dimension (N)
   On entry, the first (N-1) entries contain the subdiagonal
   elements of the tridiagonal matrix T; E(N) is set to ZERO.

 INFO
   INFO is INTEGER
   INFO = 0(default) : the matrix warrants computations preserving
       relative accuracy.
   INFO = 1          : the matrix warrants computations guaranteeing
       only absolute accuracy.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlartg (F, G, CS, SN, R)
           DLARTG generates a plane rotation with real cosine and real sine.

Function/Subroutine Documentation
   subroutine dlartg (double precision F, double precision G, double precision
       CS, double precision SN, double precision R)
       DLARTG generates a plane rotation with real cosine and real sine.

Purpose:
   DLARTG generate a plane rotation so that

      [  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
      [ -SN  CS  ]     [ G ]     [ 0 ]
```

```
   This is a slower, more accurate version of the BLAS1 routine DROTG,
   with the following other differences:
    F and G are unchanged on return.
     If G=0, then CS=1 and SN=0.
     If F=0 and (G .ne. 0), then CS=0 and SN=1 without doing any
   floating point operations (saves work in DBDSQR when
   there are zeros on the diagonal).

   If F exceeds G in magnitude, CS will be positive.

Parameters:

 F
   F is DOUBLE PRECISION
   The first component of vector to be rotated.

 G
   G is DOUBLE PRECISION
   The second component of vector to be rotated.

 CS
   CS is DOUBLE PRECISION
   The cosine of the rotation.

 SN
   SN is DOUBLE PRECISION
   The sine of the rotation.

 R
   R is DOUBLE PRECISION
   The nonzero component of the rotated vector.

   This version has a few statements commented out for thread safety
   (machine parameters are computed on each entry). 10 feb 03, SJH.

SYNOPSIS
   Functions/Subroutines
       subroutine dlartgp (F, G, CS, SN, R)
           DLARTGP generates a plane rotation so that the diagonal is
           nonnegative.

Function/Subroutine Documentation
   subroutine dlartgp (double precision F, double precision G, double
       precision CS, double precision SN, double precision R)
       DLARTGP generates a plane rotation so that the diagonal is nonnegative.

Purpose:
   DLARTGP generates a plane rotation so that

   [  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
   [ -SN  CS  ]     [ G ]     [ 0 ]

   This is a slower, more accurate version of the Level 1 BLAS routine DROTG,
   with the following other differences:
    F and G are unchanged on return.
     If G=0, then CS=(+/-)1 and SN=0.
     If F=0 and (G .ne. 0), then CS=0 and SN=(+/-)1.

   The sign is chosen so that R >= 0.

Parameters:

 F
   F is DOUBLE PRECISION
   The first component of vector to be rotated.

 G
   G is DOUBLE PRECISION
   The second component of vector to be rotated.

 CS
   CS is DOUBLE PRECISION
   The cosine of the rotation.

 SN
   SN is DOUBLE PRECISION
   The sine of the rotation.

 R
   R is DOUBLE PRECISION
   The nonzero component of the rotated vector.

   This version has a few statements commented out for thread safety
   (machine parameters are computed on each entry). 10 feb 03, SJH.

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine dlaruv (ISEED, N, X)
           DLARUV returns a vector of n random real numbers from a uniform
           distribution.

Function/Subroutine Documentation
   subroutine dlaruv (integer, dimension( 4 ) ISEED, integer N, double
       precision, dimension( n ) X)
       DLARUV returns a vector of n random real numbers from a uniform
       distribution.

Purpose:
   DLARUV returns a vector of n random real numbers from a uniform (0,1)
   distribution (n <= 128).

   This is an auxiliary routine called by DLARNV and ZLARNV.

Parameters:

 ISEED
   ISEED is INTEGER array, dimension (4)
   On entry, the seed of the random number generator; the array
   elements must be between 0 and 4095, and ISEED(4) must be odd.
   On exit, the seed is updated.

 N
   N is INTEGER
   The number of random numbers to be generated. N <= 128.

 X
   X is DOUBLE PRECISION array, dimension (N)
   The generated random numbers.

Further Details:

   This routine uses a multiplicative congruential method with modulus
   2**48 and multiplier 33952834046453 (see G.S.Fishman,
   'Multiplicative congruential random number generators with modulus
   2**b: an exhaustive analysis for b = 32 and a partial analysis for
   b = 48', Math. Comp. 189, pp 331-344, 1990).

   48-bit integers are stored in 4 integer array elements with 12 bits
   per element. Hence the routine is portable across machines with
   integers of 32 bits or more.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlas2 (F, G, H, SSMIN, SSMAX)
           DLAS2 computes singular values of a 2-by-2 triangular matrix.

Function/Subroutine Documentation
   subroutine dlas2 (double precision F, double precision G, double precision
       H, double precision SSMIN, double precision SSMAX)
       DLAS2 computes singular values of a 2-by-2 triangular matrix.

Purpose:
   DLAS2  computes the singular values of the 2-by-2 matrix
     [  F   G  ]
     [  0   H  ].
   On return, SSMIN is the smaller singular value and SSMAX is the
   larger singular value.

Parameters:

 F
   F is DOUBLE PRECISION
   The (1,1) element of the 2-by-2 matrix.

 G
   G is DOUBLE PRECISION
   The (1,2) element of the 2-by-2 matrix.

 H
   H is DOUBLE PRECISION
   The (2,2) element of the 2-by-2 matrix.

 SSMIN
   SSMIN is DOUBLE PRECISION
   The smaller singular value.

 SSMAX
   SSMAX is DOUBLE PRECISION
   The larger singular value.

Further Details:

   Barring over/underflow, all output quantities are correct to within
```

```
a few units in the last place (ulps), even in the absence of a guard
digit in addition/subtraction.

In IEEE arithmetic, the code works correctly if one matrix element is
infinite.

Overflow will not occur unless the largest singular value itself
overflows, or is within a few ulps of overflow. (On machines with
partial overflow, like the Cray, overflow may occur if the largest
singular value is within a factor of 2 of overflow.)

Underflow is harmless if underflow is gradual. Otherwise, results
may correspond to a matrix modified by perturbations of size near
the underflow threshold.

SYNOPSIS
   Functions/Subroutines
       subroutine dlascl (TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO)
           DLASCL multiplies a general rectangular matrix by a real scalar
           defined as cto/cfrom.

Function/Subroutine Documentation
   subroutine dlascl (character TYPE, integer KL, integer KU, double precision
       CFROM, double precision CTO, integer M, integer N, double precision,
       dimension( lda, * ) A, integer LDA, integer INFO)
       DLASCL multiplies a general rectangular matrix by a real scalar defined
       as cto/cfrom.

Purpose:
   DLASCL multiplies the M by N real matrix A by the real scalar
   CTO/CFROM.  This is done without over/underflow as long as the final
   result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that
   A may be full, upper triangular, lower triangular, upper Hessenberg,
   or banded.

Parameters:

 TYPE
   TYPE is CHARACTER*1
   TYPE indices the storage type of the input matrix.
   = 'G':  A is a full matrix.
   = 'L':  A is a lower triangular matrix.
   = 'U':  A is an upper triangular matrix.
   = 'H':  A is an upper Hessenberg matrix.
   = 'B':  A is a symmetric band matrix with lower bandwidth KL
      and upper bandwidth KU and with the only the lower half stored.
   = 'Q':  A is a symmetric band matrix with lower bandwidth KL
      and upper bandwidth KU and with the only the upper half stored.
   = 'Z':  A is a band matrix with lower bandwidth KL and upper
      bandwidth KU. See DGBTRF for storage details.

 KL
   KL is INTEGER
   The lower bandwidth of A.  Referenced only if TYPE = 'B', 'Q' or 'Z'.

 KU
   KU is INTEGER
   The upper bandwidth of A.  Referenced only if TYPE = 'B', 'Q' or 'Z'.

 CFROM
   CFROM is DOUBLE PRECISION

 CTO
   CTO is DOUBLE PRECISION
```

```
  The matrix A is multiplied by CTO/CFROM. A(I,J) is computed
  without over/underflow if the final result CTO*A(I,J)/CFROM
  can be represented without over/underflow.  CFROM must be nonzero.

M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The matrix to be multiplied by CTO/CFROM.  See TYPE for the storage type.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

INFO
  INFO is INTEGER
  0  - successful exit
  < 0 - if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine dlasd0 (N, SQRE, D, E, U, LDU, VT, LDVT, SMLSIZ, IWORK,
           WORK, INFO)
           DLASD0 computes the singular values of a real upper bidiagonal n-
           by-m matrix B with diagonal d and off-diagonal e. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasd0 (integer N, integer SQRE, double precision, dimension( *
       ) D, double precision, dimension( * ) E, double precision, dimension(
       ldu, * ) U, integer LDU, double precision, dimension( ldvt, * ) VT,
       integer LDVT, integer SMLSIZ, integer, dimension( * ) IWORK, double
       precision, dimension( * ) WORK, integer INFO)
       DLASD0 computes the singular values of a real upper bidiagonal n-by-m
       matrix B with diagonal d and off-diagonal e. Used by sbdsdc.

Purpose:
   Using a divide and conquer approach, DLASD0 computes the singular
   value decomposition (SVD) of a real upper bidiagonal N-by-M
   matrix B with diagonal D and offdiagonal E, where M = N + SQRE.
   The algorithm computes orthogonal matrices U and VT such that
   B = U * S * VT. The singular values S are overwritten on D.

   A related subroutine, DLASDA, computes only the singular values,
   and optionally, the singular vectors in compact form.

Parameters:

 N
   N is INTEGER
   On entry, the row dimension of the upper bidiagonal matrix.
   This is also the dimension of the main diagonal array D.

 SQRE
   SQRE is INTEGER
   Specifies the column dimension of the bidiagonal matrix.
   = 0: The bidiagonal matrix has column dimension M = N;
   = 1: The bidiagonal matrix has column dimension M = N+1;

 D
   D is DOUBLE PRECISION array, dimension (N)
   On entry D contains the main diagonal of the bidiagonal matrix.
   On exit D, if INFO = 0, contains its singular values.

 E
   E is DOUBLE PRECISION array, dimension (M-1)
   Contains the subdiagonal entries of the bidiagonal matrix.
   On exit, E has been destroyed.

 U
   U is DOUBLE PRECISION array, dimension at least (LDQ, N)
```

```
  On exit, U contains the left singular vectors.

LDU
  LDU is INTEGER
  On entry, leading dimension of U.

VT
  VT is DOUBLE PRECISION array, dimension at least (LDVT, M)
  On exit, VT**T contains the right singular vectors.

LDVT
  LDVT is INTEGER
  On entry, leading dimension of VT.

SMLSIZ
  SMLSIZ is INTEGER
  On entry, maximum size of the subproblems at the
  bottom of the computation tree.

IWORK
  IWORK is INTEGER work array.
  Dimension must be at least (8 * N)

WORK
  WORK is DOUBLE PRECISION work array.
  Dimension must be at least (3 * M**2 + 2 * M)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasd1 (NL, NR, SQRE, D, ALPHA, BETA, U, LDU, VT, LDVT,
           IDXQ, IWORK, WORK, INFO)
           DLASD1 computes the SVD of an upper bidiagonal matrix B of the
           specified size. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasd1 (integer NL, integer NR, integer SQRE, double precision,
       dimension( * ) D, double precision ALPHA, double precision BETA, double
       precision, dimension( ldu, * ) U, integer LDU, double precision,
       dimension( ldvt, * ) VT, integer LDVT, integer, dimension( * ) IDXQ,
       integer, dimension( * ) IWORK, double precision, dimension( * ) WORK,
       integer INFO)
       DLASD1 computes the SVD of an upper bidiagonal matrix B of the
       specified size. Used by sbdsdc.

Purpose:
   DLASD1 computes the SVD of an upper bidiagonal N-by-M matrix B,
   where N = NL + NR + 1 and M = N + SQRE. DLASD1 is called from DLASD0.

   A related subroutine DLASD7 handles the case in which the singular
   values (and the singular vectors in factored form) are desired.

   DLASD1 computes the SVD as follows:

                     ( D1(in)    0    0       0 )
         B = U(in) * (   Z1**T   a   Z2**T    b ) * VT(in)
                     (   0       0   D2(in)   0 )

           = U(out) * ( D(out) 0) * VT(out)

   where Z**T = (Z1**T a Z2**T b) = u**T VT**T, and u is a vector of
   dimension M with ALPHA and BETA in the NL+1 and NL+2 th entries and zeros
   elsewhere; and the entry b is empty if SQRE = 0.

   The left singular vectors of the original matrix are stored in U, and
   the transpose of the right singular vectors are stored in VT, and the
   singular values are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple singular values or when there are zeros in
```

```
  the Z vector.  For each such occurence the dimension of the
  secular equation problem is reduced by one.  This stage is
  performed by the routine DLASD2.

  The second stage consists of calculating the updated
  singular values. This is done by finding the square roots of the
  roots of the secular equation via the routine DLASD4 (as called
  by DLASD3). This routine also calculates the singular vectors of
  the current problem.

  The final stage consists of computing the updated singular vectors
  directly using the updated singular values.  The singular vectors
  for the current problem are multiplied with the singular vectors
  from the overall problem.

Parameters:

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has row dimension N = NL + NR + 1,
   and column dimension M = N + SQRE.

 D
   D is DOUBLE PRECISION array, dimension (N = NL+NR+1).
   On entry D(1:NL,1:NL) contains the singular values of the
   upper block; and D(NL+2:N) contains the singular values of
   the lower block. On exit D(1:N) contains the singular values
   of the modified matrix.

 ALPHA
   ALPHA is DOUBLE PRECISION
   Contains the diagonal element associated with the added row.

 BETA
   BETA is DOUBLE PRECISION
   Contains the off-diagonal element associated with the added row.

 U
   U is DOUBLE PRECISION array, dimension(LDU,N)
```

```
  On entry U(1:NL, 1:NL) contains the left singular vectors of
  the upper block; U(NL+2:N, NL+2:N) contains the left singular
  vectors of the lower block. On exit U contains the left
  singular vectors of the bidiagonal matrix.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= max( 1, N ).

VT
  VT is DOUBLE PRECISION array, dimension(LDVT,M)
  where M = N + SQRE.
  On entry VT(1:NL+1, 1:NL+1)**T contains the right singular
  vectors of the upper block; VT(NL+2:M, NL+2:M)**T contains
  the right singular vectors of the lower block. On exit
  VT**T contains the right singular vectors of the bidiagonal matrix.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= max( 1, M ).

IDXQ
  IDXQ is INTEGER array, dimension(N)
  This contains the permutation which will reintegrate the
  subproblem just solved back into sorted order, i.e.
  D( IDXQ( I = 1, N ) ) will be in ascending order.

IWORK
  IWORK is INTEGER array, dimension( 4 * N )

       integer, dimension( * ) IDX, integer, dimension( * ) IDXC, integer,
       dimension( * ) IDXQ, integer, dimension( * ) COLTYP, integer INFO)
       DLASD2 merges the two sets of singular values together into a single
       sorted set. Used by sbdsdc.

Purpose:
   DLASD2 merges the two sets of singular values together into a single
   sorted set.  Then it tries to deflate the size of the problem.
   There are two ways in which deflation can occur:  when two or more
   singular values are close together or if there is a tiny entry in the
   Z vector.  For each such occurrence the order of the related secular
   equation problem is reduced by one.
```

```
  DLASD2 is called from DLASD1.

Parameters:

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has N = NL + NR + 1 rows and
   M = N + SQRE >= N columns.

 K
   K is INTEGER
   Contains the dimension of the non-deflated matrix,
   This is the order of the related secular equation. 1 <= K <=N.

 D
   D is DOUBLE PRECISION array, dimension(N)
   On entry D contains the singular values of the two submatrices
   to be combined.  On exit D contains the trailing (N-K) updated
   singular values (those which were deflated) sorted into increasing order.

 Z
   Z is DOUBLE PRECISION array, dimension(N)
   On exit Z contains the updating row vector in the secular equation.

 ALPHA
   ALPHA is DOUBLE PRECISION
   Contains the diagonal element associated with the added row.

 BETA
   BETA is DOUBLE PRECISION
   Contains the off-diagonal element associated with the added row.

 U
   U is DOUBLE PRECISION array, dimension(LDU,N)
   On entry U contains the left singular vectors of two
   submatrices in the two square blocks with corners at (1,1),
   (NL, NL), and (NL+2, NL+2), (N,N).
   On exit U contains the trailing (N-K) updated left singular
   vectors (those which were deflated) in its last N-K columns.
```

```
LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= N.

VT
  VT is DOUBLE PRECISION array, dimension(LDVT,M)
  On entry VT**T contains the right singular vectors of two
  submatrices in the two square blocks with corners at (1,1),
  (NL+1, NL+1), and (NL+2, NL+2), (M,M).
  On exit VT**T contains the trailing (N-K) updated right singular
  vectors (those which were deflated) in its last N-K columns.
  In case SQRE =1, the last row of VT spans the right null space.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= M.

DSIGMA
  DSIGMA is DOUBLE PRECISION array, dimension (N)
  Contains a copy of the diagonal elements (K-1 singular values
  and one zero) in the secular equation.

U2
  U2 is DOUBLE PRECISION array, dimension(LDU2,N)
  Contains a copy of the first K-1 left singular vectors which
  will be used by DLASD3 in a matrix multiply (DGEMM) to solve
  for the new left singular vectors. U2 is arranged into four
  blocks. The first block contains a column with 1 at NL+1 and
  zero everywhere else; the second block contains non-zero
  entries only at and above NL; the third contains non-zero
  entries only below NL+1; and the fourth is dense.

LDU2
  LDU2 is INTEGER
  The leading dimension of the array U2.  LDU2 >= N.

VT2
  VT2 is DOUBLE PRECISION array, dimension(LDVT2,N)
  VT2**T contains a copy of the first K right singular vectors
  which will be used by DLASD3 in a matrix multiply (DGEMM) to
  solve for the new right singular vectors. VT2 is arranged into
  three blocks. The first block contains a row that corresponds
  to the special 0 diagonal element in SIGMA; the second block
  contains non-zeros only at and before NL +1; the third block
  contains non-zeros only at and after  NL +2.

LDVT2
  LDVT2 is INTEGER
  The leading dimension of the array VT2.  LDVT2 >= M.
```

```
IDXP
  IDXP is INTEGER array dimension(N)
  This will contain the permutation used to place deflated
  values of D at the end of the array. On output IDXP(2:K)
  points to the nondeflated D-values and IDXP(K+1:N)
  points to the deflated singular values.

IDX
  IDX is INTEGER array dimension(N)
  This will contain the permutation used to sort the contents of
  D into ascending order.

IDXC
  IDXC is INTEGER array dimension(N)
  This will contain the permutation used to arrange the columns
  of the deflated U matrix into three groups:  the first group
  contains non-zero entries only at and above NL, the second
  contains non-zero entries only below NL+2, and the third is dense.

IDXQ
  IDXQ is INTEGER array dimension(N)
  This contains the permutation which separately sorts the two
  sub-problems in D into ascending order.  Note that entries in
  the first hlaf of this permutation must first be moved one
  position backward; and entries in the second half
  must first have NL+1 added to their values.

COLTYP
  COLTYP is INTEGER array dimension(N)
  As workspace, this will contain a label which will indicate
  which of the following types a column in the U2 matrix or a
  row in the VT2 matrix is:
  1 : non-zero in the upper half only
  2 : non-zero in the lower half only
  3 : dense
  4 : deflated

  On exit, it is an array of dimension 4, with COLTYP(I) being
  the dimension of the I-th type columns.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

SYNOPSIS
   Functions/Subroutines
       subroutine dlasd3 (NL, NR, SQRE, K, D, Q, LDQ, DSIGMA, U, LDU, U2,
           LDU2, VT, LDVT, VT2, LDVT2, IDXC, CTOT, Z, INFO)
           DLASD3 finds all square roots of the roots of the secular equation,
           as defined by the values in D and Z, and then updates the singular
           vectors by matrix multiplication. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasd3 (integer NL, integer NR, integer SQRE, integer K, double
       precision, dimension( * ) D, double precision, dimension( ldq, * ) Q,
       integer LDQ, double precision, dimension( * ) DSIGMA, double precision,
       dimension( ldu, * ) U, integer LDU, double precision, dimension( ldu2,
       * ) U2, integer LDU2, double precision, dimension( ldvt, * ) VT,
       integer LDVT, double precision, dimension( ldvt2, * ) VT2, integer
       LDVT2, integer, dimension( * ) IDXC, integer, dimension( * ) CTOT,
       double precision, dimension( * ) Z, integer INFO)
       DLASD3 finds all square roots of the roots of the secular equation, as
       defined by the values in D and Z, and then updates the singular vectors
       by matrix multiplication. Used by sbdsdc.

Purpose:
   DLASD3 finds all the square roots of the roots of the secular
   equation, as defined by the values in D and Z.  It makes the
   appropriate calls to DLASD4 and then updates the singular
   vectors by matrix multiplication.

   This code makes very mild assumptions about floating point
```

```
   arithmetic. It will work on machines with a guard digit in
   add/subtract, or on those binary machines without guard digits
   which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.
   It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

   DLASD3 is called from DLASD1.

Parameters:

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has N = NL + NR + 1 rows and
   M = N + SQRE >= N columns.

 K
   K is INTEGER
   The size of the secular equation, 1 =< K = < N.

 D
   D is DOUBLE PRECISION array, dimension(K)
   On exit the square roots of the roots of the secular equation,
   in ascending order.

 Q
   Q is DOUBLE PRECISION array, dimension at least (LDQ,K).

 LDQ
   LDQ is INTEGER
   The leading dimension of the array Q.  LDQ >= K.

 DSIGMA
   DSIGMA is DOUBLE PRECISION array, dimension(K)
   The first K elements of this array contain the old roots
   of the deflated updating problem.  These are the poles
   of the secular equation.

 U
   U is DOUBLE PRECISION array, dimension (LDU, N)
```

```
  The last N - K columns of this matrix contain the deflated
  left singular vectors.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= N.

U2
  U2 is DOUBLE PRECISION array, dimension (LDU2, N)
  The first K columns of this matrix contain the non-deflated
  left singular vectors for the split problem.

LDU2
  LDU2 is INTEGER
  The leading dimension of the array U2.  LDU2 >= N.

VT
  VT is DOUBLE PRECISION array, dimension (LDVT, M)
  The last M - K columns of VT**T contain the deflated
  right singular vectors.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= N.

VT2
  VT2 is DOUBLE PRECISION array, dimension (LDVT2, N)
  The first K columns of VT2**T contain the non-deflated
  right singular vectors for the split problem.

LDVT2
  LDVT2 is INTEGER
  The leading dimension of the array VT2.  LDVT2 >= N.

IDXC
  IDXC is INTEGER array, dimension ( N )
  The permutation used to arrange the columns of U (and rows of
  VT) into three groups:  the first group contains non-zero
  entries only at and above (or before) NL +1; the second
  contains non-zero entries only at and below (or after) NL+2;
  and the third is dense. The first column of U and the row of
  VT are treated separately, however.

  The rows of the singular vectors found by DLASD4
  must be likewise permuted before the matrix multiplies can take place.

CTOT
  CTOT is INTEGER array, dimension ( 4 )
  A count of the total number of the various types of columns
  in U (or rows in VT), as described in IDXC. The fourth column
```

```
  type is any column which has been deflated.

Z
  Z is DOUBLE PRECISION array, dimension (K)
  The first K elements of this array contain the components
  of the deflation-adjusted updating row vector.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasd4 (N, I, D, Z, DELTA, RHO, SIGMA, WORK, INFO)
           DLASD4 computes the square root of the i-th updated eigenvalue of a
           positive symmetric rank-one modification to a positive diagonal
           matrix. Used by dbdsdc.

Function/Subroutine Documentation
   subroutine dlasd4 (integer N, integer I, double precision, dimension( * )
       D, double precision, dimension( * ) Z, double precision, dimension( * )
       DELTA, double precision RHO, double precision SIGMA, double precision,
       dimension( * ) WORK, integer INFO)
       DLASD4 computes the square root of the i-th updated eigenvalue of a
       positive symmetric rank-one modification to a positive diagonal matrix.
       Used by dbdsdc.

Purpose:
   This subroutine computes the square root of the I-th updated
   eigenvalue of a positive symmetric rank-one modification to
   a positive diagonal matrix whose entries are given as the squares
   of the corresponding entries in the array d, and that

   0 <= D(i) < D(j)  for  i < j

   and that RHO > 0. This is arranged by the calling routine, and is
   no loss in generality.  The rank-one modified system is thus

   diag( D ) * diag( D ) +  RHO * Z * Z_transpose.

   where we assume the Euclidean norm of Z is 1.
```

```
   The method consists of approximating the rational functions in the
   secular equation by simpler interpolating rational functions.

Parameters:

 N
   N is INTEGER
   The length of all arrays.

 I
   I is INTEGER
   The index of the eigenvalue to be computed.  1 <= I <= N.

 D
   D is DOUBLE PRECISION array, dimension ( N )
   The original eigenvalues.  It is assumed that they are in
   order, 0 <= D(I) < D(J)  for I < J.

 Z
   Z is DOUBLE PRECISION array, dimension ( N )
   The components of the updating vector.

 DELTA
   DELTA is DOUBLE PRECISION array, dimension ( N )
   If N .ne. 1, DELTA contains (D(j) - sigma_I) in its  j-th
   component.  If N = 1, then DELTA(1) = 1.  The vector DELTA
   contains the information necessary to construct the
   (singular) eigenvectors.

 RHO
   RHO is DOUBLE PRECISION
   The scalar in the symmetric updating formula.

 SIGMA
   SIGMA is DOUBLE PRECISION
   The computed sigma_I, the I-th updated eigenvalue.

 WORK
   WORK is DOUBLE PRECISION array, dimension ( N )
   If N .ne. 1, WORK contains (D(j) + sigma_I) in its  j-th
   component.  If N = 1, then WORK( 1 ) = 1.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   > 0:  if INFO = 1, the updating process failed.

Internal Parameters:

   Logical variable ORGATI (origin-at-i?) is used for distinguishing
```

```
whether D(i) or D(i+1) is treated as the origin.

ORGATI = .true.    origin at i
ORGATI = .false.   origin at i+1

Logical variable SWTCH3 (switch-for-3-poles?) is for noting
if we are working with THREE poles!

MAXIT is the maximum number of iterations allowed for each
eigenvalue.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasd5 (I, D, Z, DELTA, RHO, DSIGMA, WORK)
           DLASD5 computes the square root of the i-th eigenvalue of a
           positive symmetric rank-one modification of a 2-by-2 diagonal
           matrix. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasd5 (integer I, double precision, dimension( 2 ) D, double
       precision, dimension( 2 ) Z, double precision, dimension( 2 ) DELTA,
       double precision RHO, double precision DSIGMA, double precision,
       dimension( 2 ) WORK)
       DLASD5 computes the square root of the i-th eigenvalue of a positive
       symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by
       sbdsdc.

Purpose:
   This subroutine computes the square root of the I-th eigenvalue
   of a positive symmetric rank-one modification of a 2-by-2 diagonal
   matrix

   diag( D ) * diag( D ) +  RHO * Z * transpose(Z) .

   The diagonal entries in the array D are assumed to satisfy
```

```
   0 <= D(i) < D(j)  for  i < j .

   We also assume RHO > 0 and that the Euclidean norm of the vector Z is one.

Parameters:

 I
   I is INTEGER
   The index of the eigenvalue to be computed.  I = 1 or I = 2.

 D
   D is DOUBLE PRECISION array, dimension ( 2 )
   The original eigenvalues.  We assume 0 <= D(1) < D(2).

 Z
   Z is DOUBLE PRECISION array, dimension ( 2 )
   The components of the updating vector.

 DELTA
   DELTA is DOUBLE PRECISION array, dimension ( 2 )
   Contains (D(j) - sigma_I) in its  j-th component.
   The vector DELTA contains the information necessary
   to construct the eigenvectors.

 RHO
   RHO is DOUBLE PRECISION
   The scalar in the symmetric updating formula.

 DSIGMA
   DSIGMA is DOUBLE PRECISION
   The computed sigma_I, the I-th updated eigenvalue.

 WORK
   WORK is DOUBLE PRECISION array, dimension ( 2 )
   WORK contains (D(j) + sigma_I) in its  j-th component.

SYNOPSIS
   Functions/Subroutines
       subroutine dlasd6 (ICOMPQ, NL, NR, SQRE, D, VF, VL, ALPHA, BETA, IDXQ,
           PERM, GIVPTR, GIVCOL, LDGCOL, GIVNUM, LDGNUM, POLES, DIFL, DIFR, Z,
           K, C, S, WORK, IWORK, INFO)
           DLASD6 computes the SVD of an updated upper bidiagonal matrix
           obtained by merging two smaller ones by appending a row. Used by
           sbdsdc.

       DLASD6 computes the SVD of an updated upper bidiagonal matrix obtained
       by merging two smaller ones by appending a row. Used by sbdsdc.

Purpose:
   DLASD6 computes the SVD of an updated upper bidiagonal matrix B
   obtained by merging two smaller ones by appending a row. This
   routine is used only for the problem which requires all singular
   values and optionally singular vector matrices in factored form.
   B is an N-by-M matrix with N = NL + NR + 1 and M = N + SQRE.
   A related subroutine, DLASD1, handles the case in which all singular
   values and singular vectors of the bidiagonal matrix are desired.

   DLASD6 computes the SVD as follows:

                         ( D1(in)    0    0       0 )
             B = U(in) * (   Z1**T   a   Z2**T    b ) * VT(in)
```

```
                        (   0       0   D2(in)   0 )

              = U(out) * ( D(out) 0) * VT(out)

  where Z**T = (Z1**T a Z2**T b) = u**T VT**T, and u is a vector of
  dimension M with ALPHA and BETA in the NL+1 and NL+2 th
  entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

  The singular values of B can be computed using D1, D2, the first
  components of all the right singular vectors of the lower block, and
  the last components of all the right singular vectors of the upper
  block. These components are stored and updated in VF and VL,
  respectively, in DLASD6. Hence U and VT are not explicitly
  referenced.

  The singular values are stored in D. The algorithm consists of two
  stages:

  The first stage consists of deflating the size of the problem
  when there are multiple singular values or if there is a zero
  in the Z vector. For each such occurence the dimension of the
  secular equation problem is reduced by one. This stage is
  performed by the routine DLASD7.

  The second stage consists of calculating the updated
  singular values. This is done by finding the roots of the
  secular equation via the routine DLASD4 (as called by DLASD8).
  This routine also updates VF and VL and computes the distances
  between the updated singular values and the old singular
  values.

  DLASD6 is called from DLASDA.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed in
   factored form:
   = 0: Compute singular values only.
   = 1: Compute singular vectors in factored form as well.

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.
```

```
SQRE
  SQRE is INTEGER
  = 0: the lower block is an NR-by-NR square matrix.
  = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

  The bidiagonal matrix has row dimension N = NL + NR + 1,
  and column dimension M = N + SQRE.

D
  D is DOUBLE PRECISION array, dimension ( NL+NR+1 ).
  On entry D(1:NL,1:NL) contains the singular values of the
  upper block, and D(NL+2:N) contains the singular values
  of the lower block. On exit D(1:N) contains the singular
  values of the modified matrix.

VF
  VF is DOUBLE PRECISION array, dimension ( M )
  On entry, VF(1:NL+1) contains the first components of all
  right singular vectors of the upper block; and VF(NL+2:M)
  contains the first components of all right singular vectors
  of the lower block. On exit, VF contains the first components
  of all right singular vectors of the bidiagonal matrix.

VL
  VL is DOUBLE PRECISION array, dimension ( M )
  On entry, VL(1:NL+1) contains the  last components of all
  right singular vectors of the upper block; and VL(NL+2:M)
  contains the last components of all right singular vectors of
  the lower block. On exit, VL contains the last components of
  all right singular vectors of the bidiagonal matrix.

ALPHA
  ALPHA is DOUBLE PRECISION
  Contains the diagonal element associated with the added row.

BETA
  BETA is DOUBLE PRECISION
  Contains the off-diagonal element associated with the added row.

IDXQ
  IDXQ is INTEGER array, dimension ( N )
  This contains the permutation which will reintegrate the
  subproblem just solved back into sorted order, i.e.
  D( IDXQ( I = 1, N ) ) will be in ascending order.

PERM
  PERM is INTEGER array, dimension ( N )
  The permutations (from deflation and sorting) to be applied
  to each block. Not referenced if ICOMPQ = 0.
```

```
GIVPTR
  GIVPTR is INTEGER
  The number of Givens rotations which took place in this
  subproblem. Not referenced if ICOMPQ = 0.

GIVCOL
  GIVCOL is INTEGER array, dimension ( LDGCOL, 2 )
  Each pair of numbers indicates a pair of columns to take place
  in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL
  LDGCOL is INTEGER
  leading dimension of GIVCOL, must be at least N.

GIVNUM
  GIVNUM is DOUBLE PRECISION array, dimension ( LDGNUM, 2 )
  Each number indicates the C or S value to be used in the
  corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM
  LDGNUM is INTEGER
  The leading dimension of GIVNUM and POLES, must be at least N.

POLES
  POLES is DOUBLE PRECISION array, dimension ( LDGNUM, 2 )
  On exit, POLES(1,*) is an array containing the new singular
  values obtained from solving the secular equation, and
  POLES(2,*) is an array containing the poles in the secular
  equation. Not referenced if ICOMPQ = 0.

DIFL
  DIFL is DOUBLE PRECISION array, dimension ( N )
  On exit, DIFL(I) is the distance between I-th updated
  (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR
  DIFR is DOUBLE PRECISION array,
     dimension ( LDGNUM, 2 ) if ICOMPQ = 1 and
     dimension ( N ) if ICOMPQ = 0.
  On exit, DIFR(I, 1) is the distance between I-th updated
  (undeflated) singular value and the I+1-th (undeflated) old singular value.

  If ICOMPQ = 1, DIFR(1:K,2) is an array containing the
  normalizing factors for the right singular vector matrix.

  See DLASD8 for details on DIFL and DIFR.

Z
  Z is DOUBLE PRECISION array, dimension ( M )
  The first elements of this array contain the components
```

```
  of the deflation-adjusted updating row vector.

K
  K is INTEGER
  Contains the dimension of the non-deflated matrix,
  This is the order of the related secular equation. 1 <= K <=N.

C
  C is DOUBLE PRECISION
  C contains garbage if SQRE =0 and the C-value of a Givens
  rotation related to the right null space if SQRE = 1.

S
  S is DOUBLE PRECISION
  S contains garbage if SQRE =0 and the S-value of a Givens
  rotation related to the right null space if SQRE = 1.

WORK
  WORK is DOUBLE PRECISION array, dimension ( 4 * M )

IWORK
  IWORK is INTEGER array, dimension ( 3 * N )

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

       DLASD7 merges the two sets of singular values together into a single
       sorted set. Then it tries to deflate the size of the problem. Used by
       sbdsdc.

Purpose:
   DLASD7 merges the two sets of singular values together into a single
   sorted set. Then it tries to deflate the size of the problem. There
   are two ways in which deflation can occur:  when two or more singular
```

```
  values are close together or if there is a tiny entry in the Z
  vector. For each such occurrence the order of the related
  secular equation problem is reduced by one.

  DLASD7 is called from DLASD6.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed
   in compact form, as follows:
   = 0: Compute singular values only.
   = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

 NL
   NL is INTEGER
   The row dimension of the upper block. NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block. NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has N = NL + NR + 1 rows and
   M = N + SQRE >= N columns.

 K
   K is INTEGER
   Contains the dimension of the non-deflated matrix, this is
   the order of the related secular equation. 1 <= K <=N.

 D
   D is DOUBLE PRECISION array, dimension ( N )
   On entry D contains the singular values of the two submatrices
   to be combined. On exit D contains the trailing (N-K) updated
   singular values (those which were deflated) sorted into increasing order.

 Z
   Z is DOUBLE PRECISION array, dimension ( M )
   On exit Z contains the updating row vector in the secular equation.

 ZW
   ZW is DOUBLE PRECISION array, dimension ( M )
   Workspace for Z.
```

```
VF
  VF is DOUBLE PRECISION array, dimension ( M )
  On entry, VF(1:NL+1) contains the first components of all
  right singular vectors of the upper block; and VF(NL+2:M)
  contains the first components of all right singular vectors
  of the lower block. On exit, VF contains the first components
  of all right singular vectors of the bidiagonal matrix.

VFW
  VFW is DOUBLE PRECISION array, dimension ( M )
  Workspace for VF.

VL
  VL is DOUBLE PRECISION array, dimension ( M )
  On entry, VL(1:NL+1) contains the  last components of all
  right singular vectors of the upper block; and VL(NL+2:M)
  contains the last components of all right singular vectors
  of the lower block. On exit, VL contains the last components
  of all right singular vectors of the bidiagonal matrix.

VLW
  VLW is DOUBLE PRECISION array, dimension ( M )
  Workspace for VL.

ALPHA
  ALPHA is DOUBLE PRECISION
  Contains the diagonal element associated with the added row.

BETA
  BETA is DOUBLE PRECISION
  Contains the off-diagonal element associated with the added row.

DSIGMA
  DSIGMA is DOUBLE PRECISION array, dimension ( N )
  Contains a copy of the diagonal elements (K-1 singular values
  and one zero) in the secular equation.

IDX
  IDX is INTEGER array, dimension ( N )
  This will contain the permutation used to sort the contents of
  D into ascending order.

IDXP
  IDXP is INTEGER array, dimension ( N )
  This will contain the permutation used to place deflated
  values of D at the end of the array. On output IDXP(2:K)
  points to the nondeflated D-values and IDXP(K+1:N)
  points to the deflated singular values.

IDXQ
```

```
  IDXQ is INTEGER array, dimension ( N )
  This contains the permutation which separately sorts the two
  sub-problems in D into ascending order.  Note that entries in
  the first half of this permutation must first be moved one
  position backward; and entries in the second half
  must first have NL+1 added to their values.

PERM
  PERM is INTEGER array, dimension ( N )
  The permutations (from deflation and sorting) to be applied
  to each singular block. Not referenced if ICOMPQ = 0.

GIVPTR
  GIVPTR is INTEGER
  The number of Givens rotations which took place in this
  subproblem. Not referenced if ICOMPQ = 0.

GIVCOL
  GIVCOL is INTEGER array, dimension ( LDGCOL, 2 )
  Each pair of numbers indicates a pair of columns to take place
  in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL
  LDGCOL is INTEGER
  The leading dimension of GIVCOL, must be at least N.

GIVNUM
  GIVNUM is DOUBLE PRECISION array, dimension ( LDGNUM, 2 )
  Each number indicates the C or S value to be used in the
  corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM
  LDGNUM is INTEGER
  The leading dimension of GIVNUM, must be at least N.

C
  C is DOUBLE PRECISION
  C contains garbage if SQRE =0 and the C-value of a Givens
  rotation related to the right null space if SQRE = 1.

S
  S is DOUBLE PRECISION
  S contains garbage if SQRE =0 and the S-value of a Givens
  rotation related to the right null space if SQRE = 1.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasd8 (ICOMPQ, K, D, Z, VF, VL, DIFL, DIFR, LDDIFR, DSIGMA,
           WORK, INFO)
           DLASD8 finds the square roots of the roots of the secular equation,
           and stores, for each element in D, the distance to its two nearest
           poles. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasd8 (integer ICOMPQ, integer K, double precision, dimension(
       * ) D, double precision, dimension( * ) Z, double precision, dimension(
       * ) VF, double precision, dimension( * ) VL, double precision,
       dimension( * ) DIFL, double precision, dimension( lddifr, * ) DIFR,
       integer LDDIFR, double precision, dimension( * ) DSIGMA, double
       precision, dimension( * ) WORK, integer INFO)
       DLASD8 finds the square roots of the roots of the secular equation, and
       stores, for each element in D, the distance to its two nearest poles.
       Used by sbdsdc.

Purpose:
   DLASD8 finds the square roots of the roots of the secular equation,
   as defined by the values in DSIGMA and Z. It makes the appropriate
   calls to DLASD4, and stores, for each  element in D, the distance
   to its two nearest poles (elements in DSIGMA). It also updates
   the arrays VF and VL, the first and last components of all the
   right singular vectors of the original bidiagonal matrix.

   DLASD8 is called from DLASD6.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed in
   factored form in the calling routine:
   = 0: Compute singular values only.
   = 1: Compute singular vectors in factored form as well.
```

```
K
  K is INTEGER
  The number of terms in the rational function to be solved
  by DLASD4.  K >= 1.

D
  D is DOUBLE PRECISION array, dimension ( K )
  On output, D contains the updated singular values.

Z
  Z is DOUBLE PRECISION array, dimension ( K )
  On entry, the first K elements of this array contain the
  components of the deflation-adjusted updating row vector.
  On exit, Z is updated.

VF
  VF is DOUBLE PRECISION array, dimension ( K )
  On entry, VF contains  information passed through DBEDE8.
  On exit, VF contains the first K components of the first
  components of all right singular vectors of the bidiagonal matrix.

VL
  VL is DOUBLE PRECISION array, dimension ( K )
  On entry, VL contains  information passed through DBEDE8.
  On exit, VL contains the first K components of the last
  components of all right singular vectors of the bidiagonal matrix.

DIFL
  DIFL is DOUBLE PRECISION array, dimension ( K )
  On exit, DIFL(I) = D(I) - DSIGMA(I).

DIFR
  DIFR is DOUBLE PRECISION array,
    dimension ( LDDIFR, 2 ) if ICOMPQ = 1 and
    dimension ( K ) if ICOMPQ = 0.
  On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not
  defined and will not be referenced.

  If ICOMPQ = 1, DIFR(1:K,2) is an array containing the
  normalizing factors for the right singular vector matrix.

LDDIFR
  LDDIFR is INTEGER
  The leading dimension of DIFR, must be at least K.

DSIGMA
  DSIGMA is DOUBLE PRECISION array, dimension ( K )
  On entry, the first K elements of this array contain the old
  roots of the deflated updating problem.  These are the poles
```

```
  of the secular equation.
  On exit, the elements of DSIGMA may be very slightly altered in value.

 WORK
  WORK is DOUBLE PRECISION array, dimension at least 3 * K

 INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine dlasda (ICOMPQ, SMLSIZ, N, SQRE, D, E, U, LDU, VT, K, DIFL,
          DIFR, Z, POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM, C, S, WORK,
          IWORK, INFO)
          DLASDA computes the singular value decomposition (SVD) of a real
          upper bidiagonal matrix with diagonal d and off-diagonal e. Used by
          sbdsdc.

       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       DLASDA computes the singular value decomposition (SVD) of a real upper
       bidiagonal matrix with diagonal d and off-diagonal e. Used by sbdsdc.

Purpose:
   Using a divide and conquer approach, DLASDA computes the singular
   value decomposition (SVD) of a real upper bidiagonal N-by-M matrix
   B with diagonal D and offdiagonal E, where M = N + SQRE. The
   algorithm computes the singular values in the SVD B = U * S * VT.
   The orthogonal matrices U and VT are optionally computed in
   compact form.

   A related subroutine, DLASD0, computes the singular values and
   the singular vectors in explicit form.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed
   in compact form, as follows
   = 0: Compute singular values only.
   = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

 SMLSIZ
   SMLSIZ is INTEGER
   The maximum size of the subproblems at the bottom of the computation tree.

 N
   N is INTEGER
   The row dimension of the upper bidiagonal matrix. This is
   also the dimension of the main diagonal array D.
```

```
SQRE
  SQRE is INTEGER
  Specifies the column dimension of the bidiagonal matrix.
  = 0: The bidiagonal matrix has column dimension M = N;
  = 1: The bidiagonal matrix has column dimension M = N + 1.

D
  D is DOUBLE PRECISION array, dimension ( N )
  On entry D contains the main diagonal of the bidiagonal
  matrix. On exit D, if INFO = 0, contains its singular values.

E
  E is DOUBLE PRECISION array, dimension ( M-1 )
  Contains the subdiagonal entries of the bidiagonal matrix.
  On exit, E has been destroyed.

U
  U is DOUBLE PRECISION array,
  dimension ( LDU, SMLSIZ ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, U contains the left
  singular vector matrices of all subproblems at the bottom level.

LDU
  LDU is INTEGER, LDU = > N.
  The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT
  VT is DOUBLE PRECISION array,
  dimension ( LDU, SMLSIZ+1 ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, VT**T contains the right
  singular vector matrices of all subproblems at the bottom level.

K
  K is INTEGER array,
  dimension ( N ) if ICOMPQ = 1 and dimension 1 if ICOMPQ = 0.
  If ICOMPQ = 1, on exit, K(I) is the dimension of the I-th
  secular equation on the computation tree.

DIFL
  DIFL is DOUBLE PRECISION array, dimension ( LDU, NLVL ),
  where NLVL = floor(log_2 (N/SMLSIZ))).

DIFR
  DIFR is DOUBLE PRECISION array,
     dimension ( LDU, 2 * NLVL ) if ICOMPQ = 1 and
     dimension ( N ) if ICOMPQ = 0.
  If ICOMPQ = 1, on exit, DIFL(1:N, I) and DIFR(1:N, 2 * I - 1)
  record distances between singular values on the I-th
  level and singular values on the (I -1)-th level, and
```

```
  DIFR(1:N, 2 * I ) contains the normalizing factors for
  the right singular vector matrix. See DLASD8 for details.

Z
  Z is DOUBLE PRECISION array,
     dimension ( LDU, NLVL ) if ICOMPQ = 1 and
     dimension ( N ) if ICOMPQ = 0.
  The first K elements of Z(1, I) contain the components of
  the deflation-adjusted updating row vector for subproblems
  on the I-th level.

POLES
  POLES is DOUBLE PRECISION array,
  dimension ( LDU, 2 * NLVL ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, POLES(1, 2*I - 1) and
  POLES(1, 2*I) contain  the new and old singular values
  involved in the secular equations on the I-th level.

GIVPTR
  GIVPTR is INTEGER array,
  dimension ( N ) if ICOMPQ = 1, and not referenced if
  ICOMPQ = 0. If ICOMPQ = 1, on exit, GIVPTR( I ) records
  the number of Givens rotations performed on the I-th
  problem on the computation tree.

GIVCOL
  GIVCOL is INTEGER array,
  dimension ( LDGCOL, 2 * NLVL ) if ICOMPQ = 1, and not
  referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I,
  GIVCOL(1, 2 *I - 1) and GIVCOL(1, 2 *I) record the locations
  of Givens rotations performed on the I-th level on the computation tree.

LDGCOL
  LDGCOL is INTEGER, LDGCOL = > N.
  The leading dimension of arrays GIVCOL and PERM.

PERM
  PERM is INTEGER array,
  dimension ( LDGCOL, NLVL ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, PERM(1, I) records
  permutations done on the I-th level of the computation tree.

GIVNUM
  GIVNUM is DOUBLE PRECISION array,
  dimension ( LDU,  2 * NLVL ) if ICOMPQ = 1, and not
  referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I,
  GIVNUM(1, 2 *I - 1) and GIVNUM(1, 2 *I) record the C- and S-
  values of Givens rotations performed on the I-th level on
  the computation tree.
```

```
C
  C is DOUBLE PRECISION array,
  dimension ( N ) if ICOMPQ = 1, and dimension 1 if ICOMPQ = 0.
  If ICOMPQ = 1 and the I-th subproblem is not square, on exit,
  C( I ) contains the C-value of a Givens rotation related to
  the right null space of the I-th subproblem.

S
  S is DOUBLE PRECISION array, dimension ( N ) if
  ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1
  and the I-th subproblem is not square, on exit, S( I )
  contains the S-value of a Givens rotation related to
  the right null space of the I-th subproblem.

WORK
  WORK is DOUBLE PRECISION array, dimension
  (6 * N + (SMLSIZ + 1)*(SMLSIZ + 1)).

IWORK
  IWORK is INTEGER array.
  Dimension must be at least (7 * N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine dlasdq (UPLO, SQRE, N, NCVT, NRU, NCC, D, E, VT, LDVT, U,
           LDU, C, LDC, WORK, INFO)
           DLASDQ computes the SVD of a real bidiagonal matrix with diagonal d
           and off-diagonal e. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasdq (character UPLO, integer SQRE, integer N, integer NCVT,
       integer NRU, integer NCC, double precision, dimension( * ) D, double
       precision, dimension( * ) E, double precision, dimension( ldvt, * ) VT,
       integer LDVT, double precision, dimension( ldu, * ) U, integer LDU,
       double precision, dimension( ldc, * ) C, integer LDC, double precision,
       dimension( * ) WORK, integer INFO)
       DLASDQ computes the SVD of a real bidiagonal matrix with diagonal d and
       off-diagonal e. Used by sbdsdc.
```

```
Purpose:
   DLASDQ computes the singular value decomposition (SVD) of a real
   (upper or lower) bidiagonal matrix with diagonal D and offdiagonal
   E, accumulating the transformations if desired. Letting B denote
   the input bidiagonal matrix, the algorithm computes orthogonal
   matrices Q and P such that B = Q * S * P**T (P**T denotes the transpose
   of P). The singular values S are overwritten on D.

   The input matrix U  is changed to U  * Q  if desired.
   The input matrix VT is changed to P**T * VT if desired.
   The input matrix C  is changed to Q**T * C  if desired.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the input bidiagonal matrix
   is upper or lower bidiagonal, and wether it is square are not.
   UPLO = 'U' or 'u'   B is upper bidiagonal.
   UPLO = 'L' or 'l'   B is lower bidiagonal.

 SQRE
   SQRE is INTEGER
   = 0: then the input matrix is N-by-N.
   = 1: then the input matrix is N-by-(N+1) if UPLU = 'U' and
        (N+1)-by-N if UPLU = 'L'.

   The bidiagonal matrix has
   N = NL + NR + 1 rows and
   M = N + SQRE >= N columns.

 N
   N is INTEGER
   On entry, N specifies the number of rows and columns
   in the matrix. N must be at least 0.

 NCVT
   NCVT is INTEGER
   On entry, NCVT specifies the number of columns of
   the matrix VT. NCVT must be at least 0.

 NRU
   NRU is INTEGER
   On entry, NRU specifies the number of rows of
   the matrix U. NRU must be at least 0.

 NCC
   NCC is INTEGER
   On entry, NCC specifies the number of columns of
```

```
  the matrix C. NCC must be at least 0.

D
  D is DOUBLE PRECISION array, dimension (N)
  On entry, D contains the diagonal entries of the
  bidiagonal matrix whose SVD is desired. On normal exit,
  D contains the singular values in ascending order.

E
  E is DOUBLE PRECISION array.
  dimension is (N-1) if SQRE = 0 and N if SQRE = 1.
  On entry, the entries of E contain the offdiagonal entries
  of the bidiagonal matrix whose SVD is desired. On normal
  exit, E will contain 0. If the algorithm does not converge,
  D and E will contain the diagonal and superdiagonal entries
  of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT
  VT is DOUBLE PRECISION array, dimension (LDVT, NCVT)
  On entry, contains a matrix which on exit has been
  premultiplied by P**T, dimension N-by-NCVT if SQRE = 0
  and (N+1)-by-NCVT if SQRE = 1 (not referenced if NCVT=0).

LDVT
  LDVT is INTEGER
  On entry, LDVT specifies the leading dimension of VT as
  declared in the calling (sub) program. LDVT must be at
  least 1. If NCVT is nonzero LDVT must also be at least N.

U
  U is DOUBLE PRECISION array, dimension (LDU, N)
  On entry, contains a  matrix which on exit has been
  postmultiplied by Q, dimension NRU-by-N if SQRE = 0
  and NRU-by-(N+1) if SQRE = 1 (not referenced if NRU=0).

LDU
  LDU is INTEGER
  On entry, LDU  specifies the leading dimension of U as
  declared in the calling (sub) program. LDU must be at least max( 1, NRU )

C
  C is DOUBLE PRECISION array, dimension (LDC, NCC)
  On entry, contains an N-by-NCC matrix which on exit
  has been premultiplied by Q**T  dimension N-by-NCC if SQRE = 0
  and (N+1)-by-NCC if SQRE = 1 (not referenced if NCC=0).

LDC
  LDC is INTEGER
  On entry, LDC  specifies the leading dimension of C as
  declared in the calling (sub) program. LDC must be at
```

```
  least 1. If NCC is nonzero, LDC must also be at least N.

 WORK
  WORK is DOUBLE PRECISION array, dimension (4*N)
  Workspace. Only referenced if one of NCVT, NRU, or NCC is
  nonzero, and if N is at least 2.

 INFO
  INFO is INTEGER
  On exit, a value of 0 indicates a successful exit.
  If INFO < 0, argument number -INFO is illegal.
  If INFO > 0, the algorithm did not converge, and INFO
  specifies how many superdiagonals did not converge.

SYNOPSIS
   Functions/Subroutines
       subroutine dlasdt (N, LVL, ND, INODE, NDIML, NDIMR, MSUB)
           DLASDT creates a tree of subproblems for bidiagonal divide and
           conquer. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine dlasdt (integer N, integer LVL, integer ND, integer, dimension(
       * ) INODE, integer, dimension( * ) NDIML, integer, dimension( * )
       NDIMR, integer MSUB)
       DLASDT creates a tree of subproblems for bidiagonal divide and conquer.
       Used by sbdsdc.

Purpose:
   DLASDT creates a tree of subproblems for bidiagonal divide and conquer.

Parameters:

 N
   N is INTEGER
   On entry, the number of diagonal elements of the bidiagonal matrix.

 LVL
   LVL is INTEGER
   On exit, the number of levels on the computation tree.
```

```
ND
  ND is INTEGER
  On exit, the number of nodes on the tree.

INODE
  INODE is INTEGER array, dimension ( N )
  On exit, centers of subproblems.

NDIML
  NDIML is INTEGER array, dimension ( N )
  On exit, row dimensions of left children.

NDIMR
  NDIMR is INTEGER array, dimension ( N )
  On exit, row dimensions of right children.

MSUB
  MSUB is INTEGER
  On entry, the maximum row dimension each subproblem at the
  bottom of the tree can be of.

==========================================================================

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine dlaset (UPLO, M, N, ALPHA, BETA, A, LDA)
          DLASET initializes the off-diagonal elements and the diagonal
          elements of a matrix to given values.

Function/Subroutine Documentation
   subroutine dlaset (character UPLO, integer M, integer N, double precision
       ALPHA, double precision BETA, double precision, dimension( lda, * ) A,
       integer LDA)
       DLASET initializes the off-diagonal elements and the diagonal elements
       of a matrix to given values.

Purpose:
   DLASET initializes an m-by-n matrix A to BETA on the diagonal and
   ALPHA on the offdiagonals.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies the part of the matrix A to be set.
   = 'U': Upper triangular part is set; the strictly lower
          triangular part of A is not changed.
   = 'L': Lower triangular part is set; the strictly upper
          triangular part of A is not changed.
   Otherwise:  All of the matrix A is set.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 ALPHA
   ALPHA is DOUBLE PRECISION
   The constant to which the offdiagonal elements are to be set.

 BETA
   BETA is DOUBLE PRECISION
   The constant to which the diagonal elements are to be set.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   On exit, the leading m-by-n submatrix of A is set as follows:

   if UPLO = 'U', A(i,j) = ALPHA, 1<=i<=j-1, 1<=j<=n,
   if UPLO = 'L', A(i,j) = ALPHA, j+1<=i<=m, 1<=j<=n,
   otherwise,     A(i,j) = ALPHA, 1<=i<=m, 1<=j<=n, i.ne.j,
```

```
  and, for all UPLO, A(i,i) = BETA, 1<=i<=min(m,n).

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SYNOPSIS
   Functions/Subroutines
       subroutine dlasr (SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA)
           DLASR applies a sequence of plane rotations to a general
           rectangular matrix.

Function/Subroutine Documentation
   subroutine dlasr (character SIDE, character PIVOT, character DIRECT,
       integer M, integer N, double precision, dimension( * ) C, double
       precision, dimension( * ) S, double precision, dimension( lda, * ) A,
       integer LDA)
       DLASR applies a sequence of plane rotations to a general rectangular
```

```
      matrix.

Purpose:
   DLASR applies a sequence of plane rotations to a real matrix A,
   from either the left or the right.

   When SIDE = 'L', the transformation takes the form

   A := P*A

   and when SIDE = 'R', the transformation takes the form

   A := A*P**T

   where P is an orthogonal matrix consisting of a sequence of z plane
   rotations, with z = M when SIDE = 'L' and z = N when SIDE = 'R',
   and P**T is the transpose of P.

   When DIRECT = 'F' (Forward sequence), then

   P = P(z-1) * ... * P(2) * P(1)

   and when DIRECT = 'B' (Backward sequence), then

   P = P(1) * P(2) * ... * P(z-1)

   where P(k) is a plane rotation matrix defined by the 2-by-2 rotation

   R(k) = (  c(k)  s(k) )
        = ( -s(k)  c(k) ).

   When PIVOT = 'V' (Variable pivot), the rotation is performed
   for the plane (k,k+1), i.e., P(k) has the form

          P(k) = (  1                                          )
                 (       ...                                   )
                 (              1                              )
                 (                   c(k)  s(k)                )
                 (                  -s(k)  c(k)                )
                 (                                1             )
                 (                                     ...      )
                 (                                          1  )

   where R(k) appears as a rank-2 modification to the identity matrix in
   rows and columns k and k+1.

   When PIVOT = 'T' (Top pivot), the rotation is performed for the
   plane (1,k+1), so P(k) has the form

          P(k) = (  c(k)                    s(k)                )
```

```
                ( 1                                    )
                (      ...                             )
                (             1                        )
                ( -s(k)            c(k)                )
                (                       1              )
                (                            ...       )
                (                                  1 )
```

where R(k) appears in rows and columns 1 and k+1.

Similarly, when PIVOT = 'B' (Bottom pivot), the rotation is performed for the plane (k,z), giving P(k) the form

```
       P(k) = ( 1                                     )
              (      ...                              )
              (             1                         )
              (                  c(k)            s(k) )
              (                        1              )
              (                             ...       )
              (                                  1    )
              (                 -s(k)            c(k) )
```

where R(k) appears in rows and columns k and z. The rotations are performed without ever forming P(k) explicitly.

Parameters:

SIDE
SIDE is CHARACTER*1
Specifies whether the plane rotation matrix P is applied to A on the left or the right.
= 'L': Left, compute A := P*A
= 'R': Right, compute A:= A*P**T

PIVOT
PIVOT is CHARACTER*1
Specifies the plane for which P(k) is a plane rotation matrix.
= 'V': Variable pivot, the plane (k,k+1)
= 'T': Top pivot, the plane (1,k+1)
= 'B': Bottom pivot, the plane (k,z)

DIRECT
DIRECT is CHARACTER*1
Specifies whether P is a forward or backward sequence of plane rotations.
= 'F': Forward, P = P(z-1)*...*P(2)*P(1)
= 'B': Backward, P = P(1)*P(2)*...*P(z-1)

M
M is INTEGER
The number of rows of the matrix A. If m <= 1, an immediate

```
  return is effected.

N
  N is INTEGER
  The number of columns of the matrix A.  If n <= 1, an
  immediate return is effected.

C
  C is DOUBLE PRECISION array, dimension
     (M-1) if SIDE = 'L'
     (N-1) if SIDE = 'R'
  The cosines c(k) of the plane rotations.

S
  S is DOUBLE PRECISION array, dimension
     (M-1) if SIDE = 'L'
     (N-1) if SIDE = 'R'
  The sines s(k) of the plane rotations.  The 2-by-2 plane
  rotation part of the matrix P(k), R(k), has the form
     R(k) = (  c(k)  s(k) )
            ( -s(k)  c(k) ).

A
  A is DOUBLE PRECISION array, dimension (LDA,N)
  The M-by-N matrix A.  On exit, A is overwritten by P*A if
  SIDE = 'R' or by A*P**T if SIDE = 'L'.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

SYNOPSIS
   Functions/Subroutines
       subroutine dlassq (N, X, INCX, SCALE, SUMSQ)
           DLASSQ updates a sum of squares represented in scaled form.

Function/Subroutine Documentation
   subroutine dlassq (integer N, double precision, dimension( * ) X, integer
       INCX, double precision SCALE, double precision SUMSQ)
       DLASSQ updates a sum of squares represented in scaled form.

Purpose:
   DLASSQ  returns the values  scl  and  smsq  such that

   ( scl**2 )*smsq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,

   where  x( i ) = X( 1 + ( i - 1 )*INCX ). The value of  sumsq  is
   assumed to be non-negative and  scl  returns the value

   scl = max( scale, abs( x( i ) ) ).

   scale and sumsq must be supplied in SCALE and SUMSQ and
   scl and smsq are overwritten on SCALE and SUMSQ respectively.

   The routine makes only one pass through the vector x.
```

```
Parameters:

 N
   N is INTEGER
   The number of elements to be used from the vector X.

 X
   X is DOUBLE PRECISION array, dimension (N)
   The vector for which a scaled sum of squares is computed.
   x( i )  = X( 1 + ( i - 1 )*INCX ), 1 <= i <= n.

 INCX
   INCX is INTEGER
   The increment between successive values of the vector X.
   INCX > 0.

 SCALE
   SCALE is DOUBLE PRECISION
   On entry, the value  scale  in the equation above.
   On exit, SCALE is overwritten with  scl , the scaling factor
   for the sum of squares.

 SUMSQ
   SUMSQ is DOUBLE PRECISION
   On entry, the value  sumsq  in the equation above.
   On exit, SUMSQ is overwritten with  smsq , the basic sum of
   squares from which  scl  has been factored out.

Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine dlasv2 (F, G, H, SSMIN, SSMAX, SNR, CSR, SNL, CSL)
           DLASV2 computes the singular value decomposition of a 2-by-2
           triangular matrix.

Function/Subroutine Documentation
   subroutine dlasv2 (double precision F, double precision G, double precision
       H, double precision SSMIN, double precision SSMAX, double precision
       SNR, double precision CSR, double precision SNL, double precision CSL)
```

```
      DLASV2 computes the singular value decomposition of a 2-by-2 triangular
      matrix.

Purpose:
   DLASV2 computes the singular value decomposition of a 2-by-2
   triangular matrix
     [  F   G  ]
     [  0   H  ].
   On return, abs(SSMAX) is the larger singular value, abs(SSMIN) is the
   smaller singular value, and (CSL,SNL) and (CSR,SNR) are the left and
   right singular vectors for abs(SSMAX), giving the decomposition

     [ CSL  SNL ] [  F   G  ] [ CSR -SNR ]  =  [ SSMAX   0   ]
     [-SNL  CSL ] [  0   H  ] [ SNR  CSR ]     [  0    SSMIN ].

Parameters:

 F
   F is DOUBLE PRECISION
   The (1,1) element of the 2-by-2 matrix.

 G
   G is DOUBLE PRECISION
   The (1,2) element of the 2-by-2 matrix.

 H
   H is DOUBLE PRECISION
   The (2,2) element of the 2-by-2 matrix.

 SSMIN
   SSMIN is DOUBLE PRECISION
   abs(SSMIN) is the smaller singular value.

 SSMAX
   SSMAX is DOUBLE PRECISION
   abs(SSMAX) is the larger singular value.

 SNL
   SNL is DOUBLE PRECISION

 CSL
   CSL is DOUBLE PRECISION
   The vector (CSL, SNL) is a unit left singular vector for the
   singular value abs(SSMAX).

 SNR
   SNR is DOUBLE PRECISION

 CSR
   CSR is DOUBLE PRECISION
```

```
   The vector (CSR, SNR) is a unit right singular vector for the
   singular value abs(SSMAX).

Further Details:

   Any input parameter may be aliased with any output parameter.

   Barring over/underflow and assuming a guard digit in subtraction, all
   output quantities are correct to within a few units in the last
   place (ulps).

   In IEEE arithmetic, the code works correctly if one matrix element is
   infinite.

   Overflow will not occur unless the largest singular value itself
   overflows or is within a few ulps of overflow. (On machines with
   partial overflow, like the Cray, overflow may occur if the largest
   singular value is within a factor of 2 of overflow.)

   Underflow is harmless if underflow is gradual. Otherwise, results
   may correspond to a matrix modified by perturbations of size near
   the underflow threshold.

SYNOPSIS
   Functions/Subroutines
       integer function ieeeck (ISPEC, ZERO, ONE)
           IEEECK

Function/Subroutine Documentation
   integer function ieeeck (integer ISPEC, real ZERO, real ONE)
       IEEECK

Purpose:
   IEEECK is called from the ILAENV to verify that Infinity and
   possibly NaN arithmetic is safe (i.e. will not trap).

Parameters:

 ISPEC
```

```
   ISPEC is INTEGER
   Specifies whether to test just for inifinity arithmetic
   or whether to test for infinity and NaN arithmetic.
   = 0: Verify infinity arithmetic only.
   = 1: Verify infinity and NaN arithmetic.

 ZERO
   ZERO is REAL
   Must contain the value 0.0
   This is passed to prevent the compiler from optimizing away this code.

 ONE
   ONE is REAL
   Must contain the value 1.0
   This is passed to prevent the compiler from optimizing away this code.

 RETURN VALUE:  INTEGER
   = 0:  Arithmetic failed to produce the correct answers
   = 1:  Arithmetic produced the correct answers
```

SYNOPSIS
   Functions/Subroutines
       integer function iladlc (M, N, A, LDA)
           ILADLC scans a matrix for its last non-zero column.

Function/Subroutine Documentation
   integer function iladlc (integer M, integer N, double precision, dimension(
       lda, * ) A, integer LDA)
       ILADLC scans a matrix for its last non-zero column.

Purpose:
   ILADLC scans A for its last non-zero column.

Parameters:

 M
   M is INTEGER
   The number of rows of the matrix A.

 N
   N is INTEGER
   The number of columns of the matrix A.

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
   The m by n matrix A.

 LDA
   LDA is INTEGER
   The leading dimension of the array A. LDA >= max(1,M).
```

=====================================================================

integer function ilaenv(Integer ISPEC, character*(*) NAME,
                        character*(*) OPTS, Integer N1, Integer N2,
                        Integer N3, Integer N4)

Purpose:
   ILAENV is called from the LAPACK routines to choose problem-dependent
   parameters for the local environment. See ISPEC for a description of
   the parameters.

   ILAENV returns an INTEGER
   if ILAENV >= 0: ILAENV returns the value of the parameter specified by ISPEC
   if ILAENV < 0: if ELAENV = 0k, the kth argument had an illegal value

   This version provides a set of parameters which should give good,
   but not optimal, performance on many of the currently available
   computers. Users are encouraged to modify this subroutine to set
   the tuning parameters for their particular machine using the option
   and problem size information in the arguments.

   This routine will not function correctly if it is converted to all
   lower case. Converting it to all upper case is allowed.

Parameters:

 ISPEC
   ISPEC is INTEGER
   Specifies the parameter to be returned as the value of ILAENV
   =1: the optimal blocksize; if this value is 1, an unblocked
       algorithm will give the best performance
   =2: the minimum block size for which the block routine
       should be used; if the usable block size is less than
       this value, an unblocked routine should be used.
   =3: the crossover point (in a block routine, for N less
       than this value, an unblocked routine should be used)
   =4: the number of shifts, used in the nonsymmetric
       eigenvalue routines (DEPRECATED)
   =5: the minimum column dimension for blocking to be used;
```

```
      rectangular blocks must have dimension at least k by n,
      where k is given by ILAENV(2,...) and m by ILAENV(5,...)
  =6: the crossover point for the SVD (when reducing an m by n
      matrix to bidiagonal form, if max(m,n)/min(m,n) excees
      this value, a QR factorization is used first to reduce
      the matrix to a triangular form)
  =7: the number of processors
  =8: the crossover point for the multishift QR method
      for nonsymmetric eigenvalue problems (DEPRECATED)
  =9: maximum size of the subproblems at the bottom of the
      computation tree in the divide-and-conquer algorithm
      (used by xGELSD and xGESDD)
  =10: ieee NaN arithmetic can be trusted not to trap
  =11: infinity arithmetic can be trusted not to trap
  12 <= ISPEC <= 16
       xHSEQR or related subroutines
       see IPARMQ for detailed explanation

NAME
  NAME is CHARACTER*(*)
  The name of the calling subroutine, in either upper case or lower case.

OPTS
  OPTS is CHARACTER*(*)
  The character options to the subroutine NAME, concatenated
  into a single character string. For example, UPLO='U',
  TRANS='T', and DIAG='N' for a triangular routine would
  be specified as OPTS='UTN'

N1
  N1 is Integer

N2
  N2 is Integer

N3
  N3 is Integer

N4
  N4 is Integer
  Problem dimensions for the subroutine NAME; these may not all be required
```

subroutine ilaver(Integer VERS_MAJOR, Integer VERS_MINOR, Integer VERS_PATCH)

Purpose:
   This subroutine returns the LAPACK version.

Parameter:

 VERS_MAJOR
   return the lapack major version

  VERS_MINOR
   return the lapack minor version from the major version

  VERS_PATCH
   return the lapack patch version from the minor version

SYNOPSIS
   Functions/Subroutines
       integer function iparmq (ISPEC, NAME, OPTS, N, ILO, IHI, LWORK)
           IPARMQ

Function/Subroutine Documentation
   integer function iparmq (integer ISPEC, character, dimension( * ) NAME,
       character, dimension( * ) OPTS, integer N, integer ILO, integer IHI,
       integer LWORK)
       IPARMQ

Purpose:
   This program sets problem and machine dependent parameters
   useful for xHSEQR and related subroutines for eigenvalue
   problems. It is called whenever
   IPARMQ is called with 12 <= ISPEC <= 16

Parameters:

 ISPEC
   ISPEC is integer scalar
   ISPEC specifies which tunable parameter IPARMQ should
   return.

   ISPEC=12: (INMIN)  Matrices of order nmin or less
      are sent directly to xLAHQR, the implicit
      double shift QR algorithm.  NMIN must be at least 11.

   ISPEC=13: (INWIN)  Size of the deflation window.
     This is best set greater than or equal to
      the number of simultaneous shifts NS.
      Larger matrices benefit from larger deflation windows.

   ISPEC=14: (INIBL) Determines when to stop nibbling and
      invest in an (expensive) multi-shift QR sweep.
      If the aggressive early deflation subroutine
      finds LD converged eigenvalues from an order
      NW deflation window and LD.GT.(NW*NIBBLE)/100,
      then the next QR sweep is skipped and early
      deflation is applied immediately to the
      remaining active diagonal block.  Setting
      IPARMQ(ISPEC=14) = 0 causes TTQRE to skip a
      multi-shift QR sweep whenever early deflation
      finds a converged eigenvalue.  Setting
      IPARMQ(ISPEC=14) greater than or equal to 100
      prevents TTQRE from skipping a multi-shift QR sweep.
```

```
  ISPEC=15: (NSHFTS) The number of simultaneous shifts in
     a multi-shift QR iteration.

  ISPEC=16: (IACC22) IPARMQ is set to 0, 1 or 2 with the
     following meanings.
     0:  During the multi-shift QR/QZ sweep,
         blocked eigenvalue reordering, blocked
         Hessenberg-triangular reduction,
         reflections and/or rotations are not
         accumulated when updating the
         far-from-diagonal matrix entries.
     1:  During the multi-shift QR/QZ sweep,
         blocked eigenvalue reordering, blocked
         Hessenberg-triangular reduction,
         reflections and/or rotations are
         accumulated, and matrix-matrix
         multiplication is used to update the
         far-from-diagonal matrix entries.
     2:  During the multi-shift QR/QZ sweep,
         blocked eigenvalue reordering, blocked
         Hessenberg-triangular reduction,
         reflections and/or rotations are
         accumulated, and 2-by-2 block structure
         is exploited during matrix-matrix multiplies.
  (If xTRMM is slower than xGEMM, then
  IPARMQ(ISPEC=16)=1 may be more efficient than
  IPARMQ(ISPEC=16)=2 despite the greater level of
  arithmetic work implied by the latter choice.)

NAME
  NAME is character string
  Name of the calling subroutine

OPTS
  OPTS is character string
  This is a concatenation of the string arguments to TTQRE.

N
  N is integer scalar
  N is the order of the Hessenberg matrix H.

ILO
  ILO is INTEGER

IHI
  IHI is INTEGER
  It is assumed that H is already upper triangular
  in rows and columns 1:ILO-1 and IHI+1:N.

LWORK
```

```
   LWORK is integer scalar
   The amount of workspace available.

Further Details:
   Little is known about how best to choose these parameters.
   It is possible to use different values of the parameters
   for each of CHSEQR, DHSEQR, SHSEQR and ZHSEQR.

   It is probably best to choose different parameters for
   different matrices and different parameters at different
   times during the iteration, but this has not been
   implemented --- yet.

   The best choices of most of the parameters depend
   in an ill-understood way on the relative execution
   rate of xLAQR3 and xLAQR5 and on the nature of each
   particular eigenvalue problem.  Experiment may be the
   only practical way to determine which choices are most effective.

   Following is a list of default values supplied by IPARMQ.
   These defaults may be adjusted in order to attain better
   performance in any particular computational environment.

   IPARMQ(ISPEC=12) The xLAHQR vs xLAQR0 crossover point.
      Default: 75. (Must be at least 11.)

   IPARMQ(ISPEC=13) Recommended deflation window size.
      This depends on ILO, IHI and NS, the
      number of simultaneous shifts returned
      by IPARMQ(ISPEC=15).  The default for
      (IHI-ILO+1).LE.500 is NS.  The default
      for (IHI-ILO+1).GT.500 is 3*NS/2.

   IPARMQ(ISPEC=14) Nibble crossover point.  Default: 14.

   IPARMQ(ISPEC=15) Number of simultaneous shifts, NS.
      a multi-shift QR iteration.

   If IHI-ILO+1 is ...

                    greater than      ...but less    ... the
                    or equal to ...      than        default is

                            0               30       NS =   2+
                           30               60       NS =   4+
                           60              150       NS =  10
                          150              590       NS =  **
                          590             3000       NS =  64
                         3000             6000       NS = 128
```

```
                        6000             infinity   NS = 256

                  (+)  By default matrices of this order are
                       passed to the implicit double shift routine
                       xLAHQR.  See IPARMQ(ISPEC=12) above.   These
                       values of NS are used only in case of a rare
                       xLAHQR failure.

                  (**) The asterisks (**) indicate an ad-hoc
                       function increasing from 10 to 64.

   IPARMQ(ISPEC=16) Select structured matrix multiply.
   (See ISPEC=16 above for details.)
   Default: 3.

SYNOPSIS
   Functions/Subroutines
       logical function lsamen (N, CA, CB)
           LSAMEN

Function/Subroutine Documentation
   logical function lsamen (integer N, character*( * ) CA, character*( * ) CB)
       LSAMEN

Purpose:
   LSAMEN  tests if the first N letters of CA are the same as the
   first N letters of CB, regardless of case.
   LSAMEN returns .TRUE. if CA and CB are equivalent except for case
   and .FALSE. otherwise.  LSAMEN also returns .FALSE. if LEN( CA )
   or LEN( CB ) is less than N.

Parameters:

 N
   N is INTEGER
   The number of characters in CA and CB to be compared.

 CA
   CA is CHARACTER*(*)

 CB
   CB is CHARACTER*(*)
   CA and CB specify two character strings of length at least N.
   Only the first N characters of each string will be accessed.

SYNOPSIS
   Functions/Subroutines
       logical function sisnan (SIN)
           SISNAN tests input for NaN.

Function/Subroutine Documentation
   logical function sisnan (real SIN)
       SISNAN tests input for NaN.

Purpose:
   SISNAN returns .TRUE. if its argument is NaN, and .FALSE.
   otherwise.  To be replaced by the Fortran 2003 intrinsic in the future.

Parameters:

 SIN
   SIN is REAL
   Input to test for NaN.

SYNOPSIS
   Functions/Subroutines
       subroutine slabad (SMALL, LARGE)
           SLABAD

Function/Subroutine Documentation
   subroutine slabad (real SMALL, real LARGE)
       SLABAD

Purpose:
   SLABAD takes as input the values computed by SLAMCH for underflow and
   overflow, and returns the square root of each of these values if the
   log of LARGE is sufficiently large.  This subroutine is intended to
   identify machines with a large exponent range, such as the Crays, and
   redefine the underflow and overflow limits to be the square roots of
   the values computed by SLAMCH.  This subroutine is needed because
   SLAMCH does not compensate for poor arithmetic in the upper half of
   the exponent range, as is found on a Cray.

Parameters:

 SMALL
   SMALL is REAL
   On entry, the underflow threshold as computed by SLAMCH.
   On exit, if LOG10(LARGE) is sufficiently large, the square
   root of SMALL, otherwise unchanged.
```

```
 LARGE
   LARGE is REAL
   On entry, the overflow threshold as computed by SLAMCH.
   On exit, if LOG10(LARGE) is sufficiently large, the square
   root of LARGE, otherwise unchanged.
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slacpy (UPLO, M, N, A, LDA, B, LDB)
           SLACPY copies all or part of one two-dimensional array to another.

Function/Subroutine Documentation
   subroutine slacpy (character UPLO, integer M, integer N, real, dimension(
       lda, * ) A, integer LDA, real, dimension( ldb, * ) B, integer LDB)
       SLACPY copies all or part of one two-dimensional array to another.

Purpose:
   SLACPY copies all or part of a two-dimensional matrix A to another
   matrix B.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies the part of the matrix A to be copied to B.
   = 'U':      Upper triangular part
   = 'L':      Lower triangular part
   Otherwise:  All of the matrix A

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 A
   A is REAL array, dimension (LDA,N)
   The m by n matrix A.  If UPLO = 'U', only the upper triangle
```

```
  or trapezoid is accessed; if UPLO = 'L', only the lower
  triangle or trapezoid is accessed.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

B
  B is REAL array, dimension (LDB,N)
  On exit, B = A in the locations specified by UPLO.

LDB
  LDB is INTEGER
  The leading dimension of the array B.  LDB >= max(1,M).
```

SYNOPSIS
   Functions/Subroutines
       subroutine sladiv (A, B, C, D, P, Q)
           SLADIV performs complex division in real arithmetic, avoiding
           unnecessary overflow.
       subroutine sladiv1 (A, B, C, D, P, Q)
       real function sladiv2 (A, B, C, D, R, T)

Function/Subroutine Documentation
   subroutine sladiv (real A, real B, real C, real D, real P, real Q)
       SLADIV performs complex division in real arithmetic, avoiding
       unnecessary overflow.

Purpose:
   SLADIV performs complex division in  real arithmetic

                         a + i*b
             p + i*q = ---------
                         c + i*d

   The algorithm is due to Michael Baudin and Robert L. Smith
   and can be found in the paper
   "A Robust Complex Division in Scilab"

Parameters:

 A
   A is REAL

 B
   B is REAL

 C
   C is REAL

 D
   D is REAL
   The scalars a, b, c, and d in the above expression.

 P
   P is REAL
```

```
Q
  Q is REAL
  The scalars p and q in the above expression.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slae2 (A, B, C, RT1, RT2)
           SLAE2 computes the eigenvalues of a 2-by-2 symmetric matrix.

Function/Subroutine Documentation
   subroutine slae2 (real A, real B, real C, real RT1, real RT2)
```

```
      SLAE2 computes the eigenvalues of a 2-by-2 symmetric matrix.

Purpose:
   SLAE2  computes the eigenvalues of a 2-by-2 symmetric matrix
               [  A   B  ]
               [  B   C  ].
   On return, RT1 is the eigenvalue of larger absolute value, and RT2
   is the eigenvalue of smaller absolute value.

Parameters:

 A
   A is REAL
   The (1,1) element of the 2-by-2 matrix.

 B
   B is REAL
   The (1,2) and (2,1) elements of the 2-by-2 matrix.

 C
   C is REAL
   The (2,2) element of the 2-by-2 matrix.

 RT1
   RT1 is REAL
   The eigenvalue of larger absolute value.

 RT2
   RT2 is REAL
   The eigenvalue of smaller absolute value.

Further Details:

   RT1 is accurate to a few ulps barring over/underflow.

   RT2 may be inaccurate if there is massive cancellation in the
   determinant A*C-B*B; higher precision or correctly rounded or
   correctly truncated arithmetic would be needed to compute RT2
   accurately in all cases.

   Overflow is possible only if RT1 is within a factor of 5 of overflow.
   Underflow is harmless if the input data is 0 or exceeds
   underflow_threshold / macheps.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slaebz (IJOB, NITMAX, N, MMAX, MINP, NBMIN, ABSTOL, RELTOL,
           PIVMIN, D, E, E2, NVAL, AB, C, MOUT, NAB, WORK, IWORK, INFO)
           SLAEBZ computes the number of eigenvalues of a real symmetric
           tridiagonal matrix which are less than or equal to a given value,
           and performs other tasks required by the routine sstebz.

Function/Subroutine Documentation
   subroutine slaebz (integer IJOB, integer NITMAX, integer N, integer MMAX,
       integer MINP, integer NBMIN, real ABSTOL, real RELTOL, real PIVMIN,
       real, dimension( * ) D, real, dimension( * ) E, real, dimension( * )
       E2, integer, dimension( * ) NVAL, real, dimension( mmax, * ) AB, real,
       dimension( * ) C, integer MOUT, integer, dimension( mmax, * ) NAB,
       real, dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SLAEBZ computes the number of eigenvalues of a real symmetric
```

```
      tridiagonal matrix which are less than or equal to a given value, and
      performs other tasks required by the routine sstebz.

Purpose:
   SLAEBZ contains the iteration loops which compute and use the
   function N(w), which is the count of eigenvalues of a symmetric
   tridiagonal matrix T less than or equal to its argument  w.  It
   performs a choice of two types of loops:

   IJOB=1, followed by
   IJOB=2: It takes as input a list of intervals and returns a list of
      sufficiently small intervals whose union contains the same
      eigenvalues as the union of the original intervals.
      The input intervals are (AB(j,1),AB(j,2)], j=1,...,MINP.
      The output interval (AB(j,1),AB(j,2)] will contain
      eigenvalues NAB(j,1)+1,...,NAB(j,2), where 1 <= j <= MOUT.

   IJOB=3: It performs a binary search in each input interval
      (AB(j,1),AB(j,2)] for a point  w(j)  such that
      N(w(j))=NVAL(j), and uses  C(j)  as the starting point of
      the search.  If such a w(j) is found, then on output
      AB(j,1)=AB(j,2)=w.  If no such w(j) is found, then on output
      (AB(j,1),AB(j,2)] will be a small interval containing the
      point where N(w) jumps through NVAL(j), unless that point
      lies outside the initial interval.

   Note that the intervals are in all cases half-open intervals,
   i.e., of the form  (a,b] , which includes  b  but not  a .

   To avoid underflow, the matrix should be scaled so that its largest
   element is no greater than  overflow**(1/2) * underflow**(1/4)
   in absolute value.  To assure the most accurate computation
   of small eigenvalues, the matrix should be scaled to be
   not much smaller than that, either.

   See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal
   Matrix", Report CS41, Computer Science Dept., Stanford
   University, July 21, 1966

   Note: the arguments are, in general, *not* checked for unreasonable values.

Parameters:

 IJOB
   IJOB is INTEGER
   Specifies what is to be done:
   = 1:  Compute NAB for the initial intervals.
   = 2:  Perform bisection iteration to find eigenvalues of T.
   = 3:  Perform bisection iteration to invert N(w), i.e.,
         to find a point which has a specified number of
```

```
        eigenvalues of T to its left.
        Other values will cause SLAEBZ to return with INFO=-1.

NITMAX
  NITMAX is INTEGER
  The maximum number of "levels" of bisection to be
  performed, i.e., an interval of width W will not be made
  smaller than 2^(-NITMAX) * W.  If not all intervals
  have converged after NITMAX iterations, then INFO is set
  to the number of non-converged intervals.

N
  N is INTEGER
  The dimension n of the tridiagonal matrix T.  It must be at least 1.

MMAX
  MMAX is INTEGER
  The maximum number of intervals.  If more than MMAX intervals
  are generated, then SLAEBZ will quit with INFO=MMAX+1.

MINP
  MINP is INTEGER
  The initial number of intervals.  It may not be greater than MMAX.

NBMIN
  NBMIN is INTEGER
  The smallest number of intervals that should be processed
  using a vector loop.  If zero, then only the scalar loop will be used.

ABSTOL
  ABSTOL is REAL
  The minimum (absolute) width of an interval.  When an
  interval is narrower than ABSTOL, or than RELTOL times the
  larger (in magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  This must be at least zero.

RELTOL
  RELTOL is REAL
  The minimum relative width of an interval.  When an interval
  is narrower than ABSTOL, or than RELTOL times the larger (in
  magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  Note: this should
  always be at least radix*machine epsilon.

PIVMIN
  PIVMIN is REAL
  The minimum absolute value of a "pivot" in the Sturm sequence loop.
  This must be at least  max |e(j)**2|*safe_min  and at
  least safe_min, where safe_min is at least
  the smallest number that can divide one without overflow.
```

```
D
  D is REAL array, dimension (N)
  The diagonal elements of the tridiagonal matrix T.

E
  E is REAL array, dimension (N)
  The offdiagonal elements of the tridiagonal matrix T in
  positions 1 through N-1.  E(N) is arbitrary.

E2
  E2 is REAL array, dimension (N)
  The squares of the offdiagonal elements of the tridiagonal
  matrix T.  E2(N) is ignored.

NVAL
  NVAL is INTEGER array, dimension (MINP)
  If IJOB=1 or 2, not referenced.
  If IJOB=3, the desired values of N(w).  The elements of NVAL
  will be reordered to correspond with the intervals in AB.
  Thus, NVAL(j) on output will not, in general be the same as
  NVAL(j) on input, but it will correspond with the interval
  (AB(j,1),AB(j,2)] on output.

AB
  AB is REAL array, dimension (MMAX,2)
  The endpoints of the intervals.  AB(j,1) is  a(j), the left
  endpoint of the j-th interval, and AB(j,2) is b(j), the
  right endpoint of the j-th interval.  The input intervals
  will, in general, be modified, split, and reordered by the calculation.

C
  C is REAL array, dimension (MMAX)
  If IJOB=1, ignored.
  If IJOB=2, workspace.
  If IJOB=3, then on input C(j) should be initialized to the
             first search point in the binary search.

MOUT
  MOUT is INTEGER
  If IJOB=1, the number of eigenvalues in the intervals.
  If IJOB=2 or 3, the number of intervals output.
  If IJOB=3, MOUT will equal MINP.

NAB
  NAB is INTEGER array, dimension (MMAX,2)
  If IJOB=1, then on output NAB(i,j) will be set to N(AB(i,j)).
  If IJOB=2, then on input, NAB(i,j) should be set.  It must
     satisfy the condition:
     N(AB(i,1)) <= NAB(i,1) <= NAB(i,2) <= N(AB(i,2)),
```

```
      which means that in interval i only eigenvalues
      NAB(i,1)+1,...,NAB(i,2) will be considered.  Usually,
      NAB(i,j)=N(AB(i,j)), from a previous call to SLAEBZ with IJOB=1.
      On output, NAB(i,j) will contain
      max(na(k),min(nb(k),N(AB(i,j)))), where k is the index of
      the input interval that the output interval
      (AB(j,1),AB(j,2)] came from, and na(k) and nb(k) are the
      the input values of NAB(k,1) and NAB(k,2).
   If IJOB=3, then on output, NAB(i,j) contains N(AB(i,j)),
      unless N(w) > NVAL(i) for all search points  w , in which
      case NAB(i,1) will not be modified, i.e., the output
      value will be the same as the input value (modulo
      reorderings -- see NVAL and AB), or unless N(w) < NVAL(i)
      for all search points  w , in which case NAB(i,2) will
      not be modified.  Normally, NAB should be set to some
      distinctive value(s) before SLAEBZ is called.

 WORK
   WORK is REAL array, dimension (MMAX)
   Workspace.

 IWORK
   IWORK is INTEGER array, dimension (MMAX)
   Workspace.

 INFO
   INFO is INTEGER
   = 0:       All intervals converged.
   = 1--MMAX: The last INFO intervals did not converge.
   = MMAX+1:  More than MMAX intervals were generated.

Further Details:

   This routine is intended to be called only by other LAPACK
   routines, thus the interface is less user-friendly.  It is intended
   for two purposes:

   (a) finding eigenvalues.  In this case, SLAEBZ should have one or
       more initial intervals set up in AB, and SLAEBZ should be called
       with IJOB=1.  This sets up NAB, and also counts the eigenvalues.
       Intervals with no eigenvalues would usually be thrown out at
       this point.  Also, if not all the eigenvalues in an interval i
       are desired, NAB(i,1) can be increased or NAB(i,2) decreased.
       For example, set NAB(i,1)=NAB(i,2)-1 to get the largest
       eigenvalue.  SLAEBZ is then called with IJOB=2 and MMAX
       no smaller than the value of MOUT returned by the call with
       IJOB=1.  After this (IJOB=2) call, eigenvalues NAB(i,1)+1
       through NAB(i,2) are approximately AB(i,1) (or AB(i,2)) to the
       tolerance specified by ABSTOL and RELTOL.
```

```
   (b) finding an interval (a',b'] containing eigenvalues w(f),...,w(l).
       In this case, start with a Gershgorin interval  (a,b).  Set up
       AB to contain 2 search intervals, both initially (a,b).  One
       NVAL element should contain  f-1  and the other should contain  l
       , while C should contain a and b, resp.  NAB(i,1) should be -1
       and NAB(i,2) should be N+1, to flag an error if the desired
       interval does not lie in (a,b).  SLAEBZ is then called with
       IJOB=3.  On exit, if w(f-1) < w(f), then one of the intervals --
       j -- will have AB(j,1)=AB(j,2) and NAB(j,1)=NAB(j,2)=f-1, while
       if, to the specified tolerance, w(f-k)=...=w(f+r), k > 0 and r
       >= 0, then the interval will have  N(AB(j,1))=NAB(j,1)=f-k and
       N(AB(j,2))=NAB(j,2)=f+r.  The cases w(l) < w(l+1) and
       w(l-r)=...=w(l+k) are handled similarly.

slaev2 examples
=====================================================================

=====================================================================
Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slaev2 (A, B, C, RT1, RT2, CS1, SN1)
```

```
          SLAEV2 computes the eigenvalues and eigenvectors of a 2-by-2
          symmetric/Hermitian matrix.

Function/Subroutine Documentation
   subroutine slaev2 (real A, real B, real C, real RT1, real RT2, real CS1,
       real SN1)
       SLAEV2 computes the eigenvalues and eigenvectors of a 2-by-2
       symmetric/Hermitian matrix.

Purpose:
   SLAEV2 computes the eigendecomposition of a 2-by-2 symmetric matrix
               [  A   B  ]
               [  B   C  ].
   On return, RT1 is the eigenvalue of larger absolute value, RT2 is the
   eigenvalue of smaller absolute value, and (CS1,SN1) is the unit right
   eigenvector for RT1, giving the decomposition

               [ CS1  SN1 ] [  A   B  ] [ CS1 -SN1 ]  =  [ RT1  0  ]
               [-SN1  CS1 ] [  B   C  ] [ SN1  CS1 ]     [  0  RT2 ].

Parameters:

 A
   A is REAL
   The (1,1) element of the 2-by-2 matrix.

 B
   B is REAL
   The (1,2) element and the conjugate of the (2,1) element of
   the 2-by-2 matrix.

 C
   C is REAL
   The (2,2) element of the 2-by-2 matrix.

 RT1
   RT1 is REAL
   The eigenvalue of larger absolute value.

 RT2
   RT2 is REAL
   The eigenvalue of smaller absolute value.

 CS1
   CS1 is REAL

 SN1
   SN1 is REAL
   The vector (CS1, SN1) is a unit right eigenvector for RT1.
```

```
Further Details:

   RT1 is accurate to a few ulps barring over/underflow.

   RT2 may be inaccurate if there is massive cancellation in the
   determinant A*C-B*B; higher precision or correctly rounded or
   correctly truncated arithmetic would be needed to compute RT2
   accurately in all cases.

   CS1 and SN1 are accurate to a few ulps barring over/underflow.

   Overflow is possible only if RT1 is within a factor of 5 of overflow.
   Underflow is harmless if the input data is 0 or exceeds
   underflow_threshold / macheps.
```

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slag2d (M, N, SA, LDSA, A, LDA, INFO)
           SLAG2D converts a single precision matrix to a double precision
           matrix.

Function/Subroutine Documentation
   subroutine slag2d (integer M, integer N, real, dimension( ldsa, * ) SA,
       integer LDSA, double precision, dimension( lda, * ) A, integer LDA,
       integer INFO)
       SLAG2D converts a single precision matrix to a double precision matrix.

Purpose:
   SLAG2D converts a SINGLE PRECISION matrix, SA, to a DOUBLE
   PRECISION matrix, A.

   Note that while it is possible to overflow while converting
   from double to single, it is not possible to overflow when
   converting from single to double.

   This is an auxiliary routine so there is no argument checking.

Parameters:

 M
   M is INTEGER
   The number of lines of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.

 SA
   SA is REAL array, dimension (LDSA,N)
   On entry, the M-by-N coefficient matrix SA.

 LDSA
   LDSA is INTEGER
   The leading dimension of the array SA.  LDSA >= max(1,M).

 A
   A is DOUBLE PRECISION array, dimension (LDA,N)
```

```
  On exit, the M-by-N coefficient matrix A.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

INFO
  INFO is INTEGER
  = 0:  successful exit
```

SYNOPSIS
   Functions/Subroutines
       subroutine slagts (JOB, N, A, B, C, D, IN, Y, TOL, INFO)
```

```
          SLAGTS solves the system of equations (T-I)x = y or (T-I)Tx =
          y,where T is a general tridiagonal matrix and  a scalar, using the
          LU factorization computed by slagtf.

Function/Subroutine Documentation
   subroutine slagts (integer JOB, integer N, real, dimension( * ) A, real,
       dimension( * ) B, real, dimension( * ) C, real, dimension( * ) D,
       integer, dimension( * ) IN, real, dimension( * ) Y, real TOL, integer
       INFO)
       SLAGTS solves the system of equations (T-I)x = y or (T-I)Tx = y,where
       T is a general tridiagonal matrix and  a scalar, using the LU
       factorization computed by slagtf.

Purpose:
   SLAGTS may be used to solve one of the systems of equations

   (T - lambda*I)*x = y   or   (T - lambda*I)**T*x = y,

   where T is an n by n tridiagonal matrix, for x, following the
   factorization of (T - lambda*I) as

   (T - lambda*I) = P*L*U ,

   by routine SLAGTF. The choice of equation to be solved is
   controlled by the argument JOB, and in each case there is an option
   to perturb zero or very small diagonal elements of U, this option
   being intended for use in applications such as inverse iteration.

Parameters:

 JOB
   JOB is INTEGER
   Specifies the job to be performed by SLAGTS as follows:
   =  1: The equations  (T - lambda*I)x = y  are to be solved,
      but diagonal elements of U are not to be perturbed.
   = -1: The equations  (T - lambda*I)x = y  are to be solved
      and, if overflow would otherwise occur, the diagonal
      elements of U are to be perturbed. See argument TOL below.
   =  2: The equations  (T - lambda*I)**Tx = y  are to be solved,
      but diagonal elements of U are not to be perturbed.
   = -2: The equations  (T - lambda*I)**Tx = y  are to be solved
      and, if overflow would otherwise occur, the diagonal
      elements of U are to be perturbed. See argument TOL below.

 N
   N is INTEGER
   The order of the matrix T.

 A
   A is REAL array, dimension (N)
```

```
  On entry, A must contain the diagonal elements of U as
  returned from SLAGTF.

B
  B is REAL array, dimension (N-1)
  On entry, B must contain the first super-diagonal elements of
  U as returned from SLAGTF.

C
  C is REAL array, dimension (N-1)
  On entry, C must contain the sub-diagonal elements of L as
  returned from SLAGTF.

D
  D is REAL array, dimension (N-2)
  On entry, D must contain the second super-diagonal elements
  of U as returned from SLAGTF.

IN
  IN is INTEGER array, dimension (N)
  On entry, IN must contain details of the matrix P as returned from SLAGTF.

Y
  Y is REAL array, dimension (N)
  On entry, the right hand side vector y.
  On exit, Y is overwritten by the solution vector x.

TOL
  TOL is REAL
  On entry, with  JOB .lt. 0, TOL should be the minimum
  perturbation to be made to very small diagonal elements of U.
  TOL should normally be chosen as about eps*norm(U), where eps
  is the relative machine precision, but if TOL is supplied as
  non-positive, then it is reset to eps*max( abs( u(i,j) ) ).
  If  JOB .gt. 0  then TOL is not referenced.

  On exit, TOL is changed as described above, only if TOL is
  non-positive on entry. Otherwise TOL is unchanged.

INFO
  INFO is INTEGER
  = 0   : successful exit
  .lt. 0: if INFO = -i, the i-th argument had an illegal value
  .gt. 0: overflow would occur when computing the INFO(th)
     element of the solution vector x. This can only occur
     when JOB is supplied as positive and either means
     that a diagonal element of U is very small, or that
     the elements of the right-hand side vector y are very large.
```

SYNOPSIS
   Functions/Subroutines
       logical function slaisnan (SIN1, SIN2)
           SLAISNAN tests input for NaN by comparing two arguments for
           inequality.

Function/Subroutine Documentation
   logical function slaisnan (real SIN1, real SIN2)
       SLAISNAN tests input for NaN by comparing two arguments for inequality.

Purpose:
   This routine is not for general use.  It exists solely to avoid
   over-optimization in SISNAN.

   SLAISNAN checks for NaNs by comparing its two arguments for
   inequality.  NaN is the only floating-point value where NaN != NaN
   returns .TRUE.  To check for NaNs, pass the same variable as both
   arguments.

   A compiler must assume that the two arguments are
   not the same variable, and the test will not be optimized away.
   Interprocedural or whole-program optimization may delete this
   test.  The ISNAN functions will be replaced by the correct
   Fortran 03 intrinsic once the intrinsic is widely available.

Parameters:

 SIN1
   SIN1 is REAL

 SIN2
   SIN2 is REAL
   Two numbers to compare for inequality.

subroutine slamc1(Integer BETA, Integer T, logical RND, logical IEEE1)

Purpose:
   determines the machine parameters given by BETA, T, RND, and IEEE1

Parameters:

 BETA
   The base of the machine
 T
   The number of (BETA) digits in the mantissa

 RND
   Specifies whether proper rounding (RND=.TRUE.) or chopping (RND=.FALSE.)
   occurs in addition. This may not be a reliable guide to the way in
   which the machine performs its arithmetic.
```

```
IEEE1
  Specifies whether rounding appears to be done in the IEEE
  'round to nearest' style.

subroutine slamc2(Integer BETA, Integer T, logical RND, real EPS,
                  Integer EMIN, real RMIN, Integer EMAX, real RMAX)

Purpose:
   determines the machine parameters specified in its argument list

 BETA
   The base of the machine

 T
   The number of (BETA) digits in the mantissa

 RND
   Specifies whether proper rounding (RND=.TRUE.) or chopping (RND=.FALSE.)
   occurs in addition. This may not be a reliable guide to the way in
   which the machine performs its arithmetic.

 EPS
   The smallest positive number such that
     fl(1.0-EPS) .LT. 1.0,
   where fl denotes the computed value.

 EMIN
   The minimum exponent before (gradual) underflow occurs.

 RMIN
   The smallest normalized number for the machine, given by
     BASE**(EMIN-1)
   where BASE is the floating point value of BETA

 EMAX
   The maximum exponent before overflow occurs

 RMAX
   The largest positive number for the machine, given by
     BASE**EMAX*(1-EPS)
   where BASE is the floating point value of BETA

SYNOPSIS
   Functions/Subroutines
       real function slamch (CMACH)
           SLAMCH

Purpose:
   SLAMCH determines single precision machine parameters.

Parameters:

 CMACH
   Specifies the value to be returned by SLAMCH:
   = 'E' or 'e',   SLAMCH := eps
   = 'S' or 's ,   SLAMCH := sfmin
   = 'B' or 'b',   SLAMCH := base
   = 'P' or 'p',   SLAMCH := eps*base
```

```
= 'N' or 'n',   SLAMCH := t
= 'R' or 'r',   SLAMCH := rnd
= 'M' or 'm',   SLAMCH := emin
= 'U' or 'u',   SLAMCH := rmin
= 'L' or 'l',   SLAMCH := emax
= 'O' or 'o',   SLAMCH := rmax
where
eps   = relative machine precision
sfmin = safe minimum, such that 1/sfmin does not overflow
base  = base of the machine
prec  = eps*base
t     = number of (base) digits in the mantissa
rnd   = 1.0 when rounding occurs in addition, 0.0 otherwise
emin  = minimum exponent before (gradual) underflow
rmin  = underflow threshold - base**(emin-1)
emax  = largest exponent before overflow
rmax  = overflow threshold  - (base**emax)*(1-eps)
```

======================================================================

SYNOPSIS
   Functions/Subroutines
       integer function slaneg (N, D, LLD, SIGMA, PIVMIN, R)
           SLANEG computes the Sturm count.

Function/Subroutine Documentation
   integer function slaneg (integer N, real, dimension( * ) D, real,
       dimension( * ) LLD, real SIGMA, real PIVMIN, integer R)
       SLANEG computes the Sturm count.

Purpose:
   SLANEG computes the Sturm count, the number of negative pivots
   encountered while factoring tridiagonal T - sigma I = L D L^T.
   This implementation works directly on the factors without forming
   the tridiagonal matrix T.  The Sturm count is also the number of
   eigenvalues of T less than sigma.

   This routine is called from SLARRB.

   The current routine does not use the PIVMIN parameter but rather
   requires IEEE-754 propagation of Infinities and NaNs.  This
   routine also has no input range restrictions but does require
   default exception handling such that x/0 produces Inf when x is
   non-zero, and Inf/Inf produces NaN.  For more information, see:
```

```
Parameters:

 N
   N is INTEGER
   The order of the matrix.

 D
   D is REAL array, dimension (N)
   The N diagonal elements of the diagonal matrix D.

 LLD
   LLD is REAL array, dimension (N-1)
   The (N-1) elements L(i)*L(i)*D(i).

 SIGMA
   SIGMA is REAL
   Shift amount in T - sigma I = L D L^T.

 PIVMIN
   PIVMIN is REAL
   The minimum pivot in the Sturm sequence.  May be used
   when zero pivots are encountered on non-IEEE-754 architectures.

 R
   R is INTEGER
   The twist index for the twisted factorization that is used for the negcount.

SYNOPSIS
   Functions/Subroutines
       real function slanst (NORM, N, D, E)
           SLANST returns the value of the 1-norm, or the Frobenius norm, or
           the infinity norm, or the element of largest absolute value of a
           real symmetric tridiagonal matrix.

Function/Subroutine Documentation
   real function slanst (character NORM, integer N, real, dimension( * ) D,
       real, dimension( * ) E)
       SLANST returns the value of the 1-norm, or the Frobenius norm, or the
       infinity norm, or the element of largest absolute value of a real
       symmetric tridiagonal matrix.

Purpose:
   SLANST  returns the value of the one norm,  or the Frobenius norm, or
   the  infinity norm,  or the  element of  largest absolute value  of a
   real symmetric tridiagonal matrix A.

 Returns:

    SLANST
       SLANST = ( max(abs(A(i,j))), NORM = 'M' or 'm'
                (
                ( norm1(A),         NORM = '1', 'O' or 'o'
                (
                ( normI(A),         NORM = 'I' or 'i'
                (
                ( normF(A),         NORM = 'F', 'f', 'E' or 'e'

   where  norm1  denotes the  one norm of a matrix (maximum column sum),
   normI  denotes the  infinity norm  of a matrix  (maximum row sum) and
   normF  denotes the  Frobenius norm of a matrix (square root of sum of
   squares).  Note that  max(abs(A(i,j)))  is not a consistent matrix norm.

Parameters:

 NORM
   NORM is CHARACTER*1
   Specifies the value to be returned in SLANST as described above.

 N
   N is INTEGER
```

```
  The order of the matrix A.  N >= 0.  When N = 0, SLANST is set to zero.

 D
  D is REAL array, dimension (N)
  The diagonal elements of A.

 E
  E is REAL array, dimension (N-1)
  The (n-1) sub-diagonal or super-diagonal elements of A.
```

SYNOPSIS
   Functions/Subroutines
       real function slapy2 (X, Y)
           SLAPY2 returns sqrt(x2+y2).

Function/Subroutine Documentation
   real function slapy2 (real X, real Y)
       SLAPY2 returns sqrt(x2+y2).

Purpose:
   SLAPY2 returns sqrt(x**2+y**2), taking care not to cause unnecessary
   overflow.
```

```
Parameters:

 X
   X is REAL

 Y
   Y is REAL
   X and Y specify the values x and y.
```

======================================================================

SYNOPSIS
   Functions/Subroutines
```

```
       subroutine slarnv (IDIST, ISEED, N, X)
           SLARNV returns a vector of random numbers from a uniform or normal
           distribution.

Function/Subroutine Documentation
   subroutine slarnv (integer IDIST, integer, dimension( 4 ) ISEED, integer N,
       real, dimension( * ) X)
       SLARNV returns a vector of random numbers from a uniform or normal
       distribution.

Purpose:
   SLARNV returns a vector of n random real numbers from a uniform or
   normal distribution.

Parameters:

 IDIST
   IDIST is INTEGER
   Specifies the distribution of the random numbers:
   = 1:  uniform (0,1)
   = 2:  uniform (-1,1)
   = 3:  normal (0,1)

 ISEED
   ISEED is INTEGER array, dimension (4)
   On entry, the seed of the random number generator; the array
   elements must be between 0 and 4095, and ISEED(4) must be odd.
   On exit, the seed is updated.

 N
   N is INTEGER
   The number of random numbers to be generated.

 X
   X is REAL array, dimension (N)
   The generated random numbers.

Further Details:

   This routine calls the auxiliary routine SLARUV to generate random
   real numbers from a uniform (0,1) distribution, in batches of up to
   128 using vectorisable code. The Box-Muller method is used to
   transform numbers from a uniform to a normal distribution.

======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slarra (N, D, E, E2, SPLTOL, TNRM, NSPLIT, ISPLIT, INFO)
           SLARRA computes the splitting points with the specified threshold.

Function/Subroutine Documentation
   subroutine slarra (integer N, real, dimension( * ) D, real, dimension( * )
       E, real, dimension( * ) E2, real SPLTOL, real TNRM, integer NSPLIT,
       integer, dimension( * ) ISPLIT, integer INFO)
       SLARRA computes the splitting points with the specified threshold.

Purpose:
   Compute the splitting points with threshold SPLTOL.
   SLARRA sets any "small" off-diagonal elements to zero.

Parameters:

 N
   N is INTEGER
   The order of the matrix. N > 0.

 D
   D is REAL array, dimension (N)
   On entry, the N diagonal elements of the tridiagonal matrix T.
```

```
E
  E is REAL array, dimension (N)
  On entry, the first (N-1) entries contain the subdiagonal
  elements of the tridiagonal matrix T; E(N) need not be set.
  On exit, the entries E( ISPLIT( I ) ), 1 <= I <= NSPLIT,
  are set to zero, the other entries of E are untouched.

E2
  E2 is REAL array, dimension (N)
  On entry, the first (N-1) entries contain the SQUARES of the
  subdiagonal elements of the tridiagonal matrix T;
  E2(N) need not be set.
  On exit, the entries E2( ISPLIT( I ) ),
  1 <= I <= NSPLIT, have been set to zero

SPLTOL
  SPLTOL is REAL
  The threshold for splitting. Two criteria can be used:
  SPLTOL<0 : criterion based on absolute off-diagonal value
  SPLTOL>0 : criterion that preserves relative accuracy

TNRM
  TNRM is REAL
  The norm of the matrix.

NSPLIT
  NSPLIT is INTEGER
  The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT
  ISPLIT is INTEGER array, dimension (N)
  The splitting points, at which T breaks up into blocks.
  The first block consists of rows/columns 1 to ISPLIT(1),
  the second of rows/columns ISPLIT(1)+1 through ISPLIT(2),
  etc., and the NSPLIT-th consists of rows/columns
  ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

INFO
  INFO is INTEGER
  = 0:  successful exit
```

SYNOPSIS
   Functions/Subroutines
       subroutine slarrb (N, D, LLD, IFIRST, ILAST, RTOL1, RTOL2, OFFSET, W,
```

```
          WGAP, WERR, WORK, IWORK, PIVMIN, SPDIAM, TWIST, INFO)
          SLARRB provides limited bisection to locate eigenvalues for more
          accuracy.

Function/Subroutine Documentation
   subroutine slarrb (integer N, real, dimension( * ) D, real, dimension( * )
       LLD, integer IFIRST, integer ILAST, real RTOL1, real RTOL2, integer
       OFFSET, real, dimension( * ) W, real, dimension( * ) WGAP, real,
       dimension( * ) WERR, real, dimension( * ) WORK, integer, dimension( * )
       IWORK, real PIVMIN, real SPDIAM, integer TWIST, integer INFO)
       SLARRB provides limited bisection to locate eigenvalues for more
       accuracy.

Purpose:
   Given the relatively robust representation(RRR) L D L^T, SLARRB
   does "limited" bisection to refine the eigenvalues of L D L^T,
   W( IFIRST-OFFSET ) through W( ILAST-OFFSET ), to more accuracy. Initial
   guesses for these eigenvalues are input in W, the corresponding estimate
   of the error in these guesses and their gaps are input in WERR
   and WGAP, respectively. During bisection, intervals
   [left, right] are maintained by storing their mid-points and
   semi-widths in the arrays W and WERR respectively.

Parameters:

 N
   N is INTEGER
   The order of the matrix.

 D
   D is REAL array, dimension (N)
   The N diagonal elements of the diagonal matrix D.

 LLD
   LLD is REAL array, dimension (N-1)
   The (N-1) elements L(i)*L(i)*D(i).

 IFIRST
   IFIRST is INTEGER
   The index of the first eigenvalue to be computed.

 ILAST
   ILAST is INTEGER
   The index of the last eigenvalue to be computed.

 RTOL1
   RTOL1 is REAL

 RTOL2
   RTOL2 is REAL
```

```
  Tolerance for the convergence of the bisection intervals.
  An interval [LEFT,RIGHT] has converged if
  RIGHT-LEFT.LT.MAX( RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|) )
  where GAP is the (estimated) distance to the nearest eigenvalue.

OFFSET
  OFFSET is INTEGER
  Offset for the arrays W, WGAP and WERR, i.e., the IFIRST-OFFSET
  through ILAST-OFFSET elements of these arrays are to be used.

W
  W is REAL array, dimension (N)
  On input, W( IFIRST-OFFSET ) through W( ILAST-OFFSET ) are
  estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST.
  On output, these estimates are refined.

WGAP
  WGAP is REAL array, dimension (N-1)
  On input, the (estimated) gaps between consecutive
  eigenvalues of L D L^T, i.e., WGAP(I-OFFSET) is the gap between
  eigenvalues I and I+1. Note that if IFIRST.EQ.ILAST
  then WGAP(IFIRST-OFFSET) must be set to ZERO.
  On output, these gaps are refined.

WERR
  WERR is REAL array, dimension (N)
  On input, WERR( IFIRST-OFFSET ) through WERR( ILAST-OFFSET ) are
  the errors in the estimates of the corresponding elements in W.
  On output, these errors are refined.

WORK
  WORK is REAL array, dimension (2*N)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (2*N)
  Workspace.

PIVMIN
  PIVMIN is REAL
  The minimum pivot in the Sturm sequence.

SPDIAM
  SPDIAM is REAL
  The spectral diameter of the matrix.

TWIST
  TWIST is INTEGER
  The twist index for the twisted factorization that is used
  for the negcount.
```

```
  TWIST = N: Compute negcount from L D L^T - LAMBDA I = L+ D+ L+^T
  TWIST = 1: Compute negcount from L D L^T - LAMBDA I = U- D- U-^T
  TWIST = R: Compute negcount from L D L^T - LAMBDA I = N(r) D(r) N(r)

 INFO
  INFO is INTEGER
  Error flag.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slarrc (JOBT, N, VL, VU, D, E, PIVMIN, EIGCNT, LCNT, RCNT,
           INFO)
           SLARRC computes the number of eigenvalues of the symmetric
           tridiagonal matrix.

Function/Subroutine Documentation
   subroutine slarrc (character JOBT, integer N, real VL, real VU, real,
       dimension( * ) D, real, dimension( * ) E, real PIVMIN, integer EIGCNT,
       integer LCNT, integer RCNT, integer INFO)
       SLARRC computes the number of eigenvalues of the symmetric tridiagonal
       matrix.

Purpose:
   Find the number of eigenvalues of the symmetric tridiagonal matrix T
   that are in the interval (VL,VU] if JOBT = 'T', and of L D L^T
   if JOBT = 'L'.

Parameters:

 JOBT
   JOBT is CHARACTER*1
   = 'T':  Compute Sturm count for matrix T.
   = 'L':  Compute Sturm count for matrix L D L^T.

 N
   N is INTEGER
   The order of the matrix. N > 0.

 VL
   VL is DOUBLE PRECISION

 VU
   VU is DOUBLE PRECISION
   The lower and upper bounds for the eigenvalues.

 D
   D is DOUBLE PRECISION array, dimension (N)
   JOBT = 'T': The N diagonal elements of the tridiagonal matrix T.
   JOBT = 'L': The N diagonal elements of the diagonal matrix D.

 E
   E is DOUBLE PRECISION array, dimension (N)
   JOBT = 'T': The N-1 offdiagonal elements of the matrix T.
```

```
  JOBT = 'L': The N-1 offdiagonal elements of the matrix L.

PIVMIN
  PIVMIN is REAL
  The minimum pivot in the Sturm sequence for T.

EIGCNT
  EIGCNT is INTEGER
  The number of eigenvalues of the symmetric tridiagonal matrix T
  that are in the interval (VL,VU]

LCNT
  LCNT is INTEGER

RCNT
  RCNT is INTEGER
  The left and right negcounts of the interval.

INFO
  INFO is INTEGER
```

SYNOPSIS
   Functions/Subroutines
```

```
      subroutine slarrd (RANGE, ORDER, N, VL, VU, IL, IU, GERS, RELTOL, D, E,
          E2, PIVMIN, NSPLIT, ISPLIT, M, W, WERR, WL, WU, IBLOCK, INDEXW,
          WORK, IWORK, INFO)
          SLARRD computes the eigenvalues of a symmetric tridiagonal matrix
          to suitable accuracy.

Function/Subroutine Documentation
   subroutine slarrd (character RANGE, character ORDER, integer N, real VL,
       real VU, integer IL, integer IU, real, dimension( * ) GERS, real
       RELTOL, real, dimension( * ) D, real, dimension( * ) E, real,
       dimension( * ) E2, real PIVMIN, integer NSPLIT, integer, dimension( * )
       ISPLIT, integer M, real, dimension( * ) W, real, dimension( * ) WERR,
       real WL, real WU, integer, dimension( * ) IBLOCK, integer, dimension( *
       ) INDEXW, real, dimension( * ) WORK, integer, dimension( * ) IWORK,
       integer INFO)
       SLARRD computes the eigenvalues of a symmetric tridiagonal matrix to
       suitable accuracy.

Purpose:
   SLARRD computes the eigenvalues of a symmetric tridiagonal
   matrix T to suitable accuracy. This is an auxiliary code to be
   called from SSTEMR.
   The user may ask for all eigenvalues, all eigenvalues
   in the half-open interval (VL, VU], or the IL-th through IU-th
   eigenvalues.

   To avoid overflow, the matrix must be scaled so that its
   largest element is no greater than
     overflow**(1/2) * underflow**(1/4)
   in absolute value, and for greatest
   accuracy, it should not be much smaller than that.

Parameters:

 RANGE
   RANGE is CHARACTER*1
   = 'A': ("All")   all eigenvalues will be found.
   = 'V': ("Value") all eigenvalues in the half-open interval
          (VL, VU] will be found.
   = 'I': ("Index") the IL-th through IU-th eigenvalues (of the
           entire matrix) will be found.

 ORDER
   ORDER is CHARACTER*1
   = 'B': ("By Block") the eigenvalues will be grouped by
          split-off block (see IBLOCK, ISPLIT) and
          ordered from smallest to largest within the block.
   = 'E': ("Entire matrix")
          the eigenvalues for the entire matrix
          will be ordered from smallest to largest.
```

```
N
  N is INTEGER
  The order of the tridiagonal matrix T.  N >= 0.

VL
  VL is REAL

VU
  VU is REAL
  If RANGE='V', the lower and upper bounds of the interval to
  be searched for eigenvalues.  Eigenvalues less than or equal
  to VL, or greater than VU, will not be returned.  VL < VU.
  Not referenced if RANGE = 'A' or 'I'.

IL
  IL is INTEGER

IU
  IU is INTEGER
  If RANGE='I', the indices (in ascending order) of the
  smallest and largest eigenvalues to be returned.
  1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0.
  Not referenced if RANGE = 'A' or 'V'.

GERS
  GERS is REAL array, dimension (2*N)
  The N Gerschgorin intervals (the i-th Gerschgorin interval
  is (GERS(2*i-1), GERS(2*i)).

RELTOL
  RELTOL is REAL
  The minimum relative width of an interval.  When an interval
  is narrower than RELTOL times the larger (in
  magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  Note: this should
  always be at least radix*machine epsilon.

D
  D is REAL array, dimension (N)
  The n diagonal elements of the tridiagonal matrix T.

E
  E is REAL array, dimension (N-1)
  The (n-1) off-diagonal elements of the tridiagonal matrix T.

E2
  E2 is REAL array, dimension (N-1)
  The (n-1) squared off-diagonal elements of the tridiagonal matrix T.
```

```
PIVMIN
  PIVMIN is REAL
  The minimum pivot allowed in the Sturm sequence for T.

NSPLIT
  NSPLIT is INTEGER
  The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

ISPLIT
  ISPLIT is INTEGER array, dimension (N)
  The splitting points, at which T breaks up into submatrices.
  The first submatrix consists of rows/columns 1 to ISPLIT(1),
  the second of rows/columns ISPLIT(1)+1 through ISPLIT(2),
  etc., and the NSPLIT-th consists of rows/columns
  ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.
  (Only the first NSPLIT elements will actually be used, but
  since the user cannot know a priori what value NSPLIT will
  have, N words must be reserved for ISPLIT.)

M
  M is INTEGER
  The actual number of eigenvalues found. 0 <= M <= N.
  (See also the description of INFO=2,3.)

W
  W is REAL array, dimension (N)
  On exit, the first M elements of W will contain the
  eigenvalue approximations. SLARRD computes an interval
  I_j = (a_j, b_j] that includes eigenvalue j. The eigenvalue
  approximation is given as the interval midpoint
  W(j)= ( a_j + b_j)/2. The corresponding error is bounded by
  WERR(j) = abs( a_j - b_j)/2

WERR
  WERR is REAL array, dimension (N)
  The error bound on the corresponding eigenvalue approximation in W.

WL
  WL is REAL

WU
  WU is REAL
  The interval (WL, WU] contains all the wanted eigenvalues.
  If RANGE='V', then WL=VL and WU=VU.
  If RANGE='A', then WL and WU are the global Gerschgorin bounds
      on the spectrum.
  If RANGE='I', then WL and WU are computed by SLAEBZ from the
      index range specified.

IBLOCK
```

```
  IBLOCK is INTEGER array, dimension (N)
  At each row/column j where E(j) is zero or small, the
  matrix T is considered to split into a block diagonal
  matrix.  On exit, if INFO = 0, IBLOCK(i) specifies to which
  block (from 1 to the number of blocks) the eigenvalue W(i)
  belongs.  (SLARRD may use the remaining N-M elements as workspace.)

 INDEXW
  INDEXW is INTEGER array, dimension (N)
  The indices of the eigenvalues within each block (submatrix);
  for example, INDEXW(i)= j and IBLOCK(i)=k imply that the
  i-th eigenvalue W(i) is the j-th eigenvalue in block k.

 WORK
  WORK is REAL array, dimension (4*N)

 IWORK
  IWORK is INTEGER array, dimension (3*N)

 INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  if INFO = -i, the i-th argument had an illegal value
  > 0:  some or all of the eigenvalues failed to converge or
        were not computed:
  =1 or 3: Bisection failed to converge for some
        eigenvalues; these eigenvalues are flagged by a
        negative block number.  The effect is that the
        eigenvalues may not be as accurate as the
        absolute and relative tolerances.  This is
        generally caused by unexpectedly inaccurate arithmetic.
  =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found.
        Effect: M < IU+1-IL
        Cause:  non-monotonic arithmetic, causing the
                Sturm sequence to be non-monotonic.
        Cure:   recalculate, using RANGE='A', and pick
                out eigenvalues IL:IU.  In some cases,
                increasing the PARAMETER "FUDGE" may make things work.
  = 4:    RANGE='I', and the Gershgorin interval
        initially used was too small.  No eigenvalues were computed.
        Probable cause: your machine has sloppy floating-point arithmetic.
        Cure: Increase the PARAMETER "FUDGE", recompile, and try again.

Internal Parameters:

 FUDGE   REAL, default = 2
  A "fudge factor" to widen the Gershgorin intervals.  Ideally,
  a value of 1 should work, but on machines with sloppy
  arithmetic, this needs to be larger.  The default for
  publicly released versions should be large enough to handle
```

```
the worst machine around.  Note that this has no effect
on accuracy of the solution.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slarre (RANGE, N, VL, VU, IL, IU, D, E, E2, RTOL1, RTOL2,
           SPLTOL, NSPLIT, ISPLIT, M, W, WERR, WGAP, IBLOCK, INDEXW, GERS,
           PIVMIN, WORK, IWORK, INFO)
           SLARRE given the tridiagonal matrix T, sets small off-diagonal
           elements to zero and for each unreduced block Ti, finds base
           representations and eigenvalues.

Function/Subroutine Documentation
   subroutine slarre (character RANGE, integer N, real VL, real VU, integer
       IL, integer IU, real, dimension( * ) D, real, dimension( * ) E, real,
       dimension( * ) E2, real RTOL1, real RTOL2, real SPLTOL, integer NSPLIT,
       integer, dimension( * ) ISPLIT, integer M, real, dimension( * ) W,
       real, dimension( * ) WERR, real, dimension( * ) WGAP, integer,
       dimension( * ) IBLOCK, integer, dimension( * ) INDEXW, real, dimension(
       * ) GERS, real PIVMIN, real, dimension( * ) WORK, integer, dimension( *
       ) IWORK, integer INFO)
       SLARRE given the tridiagonal matrix T, sets small off-diagonal elements
       to zero and for each unreduced block Ti, finds base representations and
       eigenvalues.

Purpose:
   To find the desired eigenvalues of a given real symmetric
   tridiagonal matrix T, SLARRE sets any "small" off-diagonal
   elements to zero, and for each unreduced block T_i, it finds
   (a) a suitable shift at one end of the block's spectrum,
   (b) the base representation, T_i - sigma_i I = L_i D_i L_i^T, and
   (c) eigenvalues of each L_i D_i L_i^T.
   The representations and eigenvalues found are then used by
   SSTEMR to compute the eigenvectors of T.
   The accuracy varies depending on whether bisection is used to
   find a few eigenvalues or the dqds algorithm (subroutine SLASQ2) to
   conpute all and then discard any unwanted one.
   As an added benefit, SLARRE also outputs the n
   Gerschgorin intervals for the matrices L_i D_i L_i^T.
```

```
Parameters:

 RANGE
   RANGE is CHARACTER*1
   = 'A': ("All")   all eigenvalues will be found.
   = 'V': ("Value") all eigenvalues in the half-open interval
          (VL, VU] will be found.
   = 'I': ("Index") the IL-th through IU-th eigenvalues (of the
           entire matrix) will be found.

 N
   N is INTEGER
   The order of the matrix. N > 0.

 VL
   VL is REAL

 VU
   VU is REAL
   If RANGE='V', the lower and upper bounds for the eigenvalues.
   Eigenvalues less than or equal to VL, or greater than VU,
   will not be returned.  VL < VU.
   If RANGE='I' or ='A', SLARRE computes bounds on the desired
   part of the spectrum.

 IL
   IL is INTEGER

 IU
   IU is INTEGER
   If RANGE='I', the indices (in ascending order) of the
   smallest and largest eigenvalues to be returned.
   1 <= IL <= IU <= N.

 D
   D is REAL array, dimension (N)
   On entry, the N diagonal elements of the tridiagonal matrix T.
   On exit, the N diagonal elements of the diagonal matrices D_i.

 E
   E is REAL array, dimension (N)
   On entry, the first (N-1) entries contain the subdiagonal
   elements of the tridiagonal matrix T; E(N) need not be set.
   On exit, E contains the subdiagonal elements of the unit
   bidiagonal matrices L_i. The entries E( ISPLIT( I ) ),
   1 <= I <= NSPLIT, contain the base points sigma_i on output.

 E2
   E2 is REAL array, dimension (N)
   On entry, the first (N-1) entries contain the SQUARES of the
```

```
  subdiagonal elements of the tridiagonal matrix T;
  E2(N) need not be set.
  On exit, the entries E2( ISPLIT( I ) ),
  1 <= I <= NSPLIT, have been set to zero

RTOL1
  RTOL1 is REAL

RTOL2
  RTOL2 is REAL
  Parameters for bisection.
  An interval [LEFT,RIGHT] has converged if
  RIGHT-LEFT.LT.MAX( RTOL1*GAP, RTOL2*MAX(|LEFT|,|RIGHT|) )

SPLTOL
  SPLTOL is REAL
  The threshold for splitting.

NSPLIT
  NSPLIT is INTEGER
  The number of blocks T splits into. 1 <= NSPLIT <= N.

ISPLIT
  ISPLIT is INTEGER array, dimension (N)
  The splitting points, at which T breaks up into blocks.
  The first block consists of rows/columns 1 to ISPLIT(1),
  the second of rows/columns ISPLIT(1)+1 through ISPLIT(2),
  etc., and the NSPLIT-th consists of rows/columns
  ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N.

M
  M is INTEGER
  The total number of eigenvalues (of all L_i D_i L_i^T) found.

W
  W is REAL array, dimension (N)
  The first M elements contain the eigenvalues. The
  eigenvalues of each of the blocks, L_i D_i L_i^T, are
  sorted in ascending order ( SLARRE may use the
  remaining N-M elements as workspace).

WERR
  WERR is REAL array, dimension (N)
  The error bound on the corresponding eigenvalue in W.

WGAP
  WGAP is REAL array, dimension (N)
  The separation from the right neighbor eigenvalue in W.
  The gap is only with respect to the eigenvalues of the same block
  as each block has its own representation tree.
```

```
  Exception: at the right end of a block we store the left gap

IBLOCK
  IBLOCK is INTEGER array, dimension (N)
  The indices of the blocks (submatrices) associated with the
  corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue
  W(i) belongs to the first block from the top, =2 if W(i)
  belongs to the second block, etc.

INDEXW
  INDEXW is INTEGER array, dimension (N)
  The indices of the eigenvalues within each block (submatrix);
  for example, INDEXW(i)= 10 and IBLOCK(i)=2 imply that the
  i-th eigenvalue W(i) is the 10-th eigenvalue in block 2

GERS
  GERS is REAL array, dimension (2*N)
  The N Gerschgorin intervals (the i-th Gerschgorin interval
  is (GERS(2*i-1), GERS(2*i)).

PIVMIN
  PIVMIN is REAL
  The minimum pivot in the Sturm sequence for T.

WORK
  WORK is REAL array, dimension (6*N)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (5*N)
  Workspace.

INFO
  INFO is INTEGER
  = 0:  successful exit
  > 0:  A problem occured in SLARRE.
  < 0:  One of the called subroutines signaled an internal problem.
        Needs inspection of the corresponding parameter IINFO
        for further information.

  =-1:  Problem in SLARRD.
  = 2:  No base representation could be found in MAXTRY iterations.
        Increasing MAXTRY and recompilation might be a remedy.
  =-3:  Problem in SLARRB when computing the refined root
        representation for SLASQ2.
  =-4:  Problem in SLARRB when preforming bisection on the
        desired part of the spectrum.
  =-5:  Problem in SLASQ2.
  =-6:  Problem in SLASQ2.
```

```
Further Details:

   The base representations are required to suffer very little
   element growth and consequently define all their eigenvalues to
   high relative accuracy.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slarrf (N, D, L, LD, CLSTRT, CLEND, W, WGAP, WERR, SPDIAM,
           CLGAPL, CLGAPR, PIVMIN, SIGMA, DPLUS, LPLUS, WORK, INFO)
           SLARRF finds a new relatively robust representation such that at
           least one of the eigenvalues is relatively isolated.

Function/Subroutine Documentation
   subroutine slarrf (integer N, real, dimension( * ) D, real, dimension( * )
       L, real, dimension( * ) LD, integer CLSTRT, integer CLEND, real,
       dimension( * ) W, real, dimension( * ) WGAP, real, dimension( * ) WERR,
       real SPDIAM, real CLGAPL, real CLGAPR, real PIVMIN, real SIGMA, real,
       dimension( * ) DPLUS, real, dimension( * ) LPLUS, real, dimension( * )
       WORK, integer INFO)
       SLARRF finds a new relatively robust representation such that at least
       one of the eigenvalues is relatively isolated.

Purpose:
   Given the initial representation L D L^T and its cluster of close
   eigenvalues (in a relative measure), W( CLSTRT ), W( CLSTRT+1 ), ...
   W( CLEND ), SLARRF finds a new relatively robust representation
   L D L^T - SIGMA I = L(+) D(+) L(+)^T such that at least one of the
   eigenvalues of L(+) D(+) L(+)^T is relatively isolated.

Parameters:

 N
   N is INTEGER
```

```
  The order of the matrix (subblock, if the matrix splitted).

D
  D is REAL array, dimension (N)
  The N diagonal elements of the diagonal matrix D.

L
  L is REAL array, dimension (N-1)
  The (N-1) subdiagonal elements of the unit bidiagonal matrix L.

LD
  LD is REAL array, dimension (N-1)
  The (N-1) elements L(i)*D(i).

CLSTRT
  CLSTRT is INTEGER
  The index of the first eigenvalue in the cluster.

CLEND
  CLEND is INTEGER
  The index of the last eigenvalue in the cluster.

W
  W is REAL array, dimension
  dimension is >=  (CLEND-CLSTRT+1)
  The eigenvalue APPROXIMATIONS of L D L^T in ascending order.
  W( CLSTRT ) through W( CLEND ) form the cluster of relatively
  close eigenalues.

WGAP
  WGAP is REAL array, dimension
  dimension is >=  (CLEND-CLSTRT+1)
  The separation from the right neighbor eigenvalue in W.

WERR
  WERR is REAL array, dimension
  dimension is >=  (CLEND-CLSTRT+1)
  WERR contain the semiwidth of the uncertainty
  interval of the corresponding eigenvalue APPROXIMATION in W

SPDIAM
  SPDIAM is REAL
  estimate of the spectral diameter obtained from the Gerschgorin intervals

CLGAPL
  CLGAPL is REAL

CLGAPR
  CLGAPR is REAL
  absolute gap on each end of the cluster.
```

```
  Set by the calling routine to protect against shifts too close
  to eigenvalues outside the cluster.

PIVMIN
  PIVMIN is REAL
  The minimum pivot allowed in the Sturm sequence.

SIGMA
  SIGMA is REAL
  The shift used to form L(+) D(+) L(+)^T.

DPLUS
  DPLUS is REAL array, dimension (N)
  The N diagonal elements of the diagonal matrix D(+).

LPLUS
  LPLUS is REAL array, dimension (N-1)
  The first (N-1) elements of LPLUS contain the subdiagonal
  elements of the unit bidiagonal matrix L(+).

WORK
  WORK is REAL array, dimension (2*N)
  Workspace.

INFO
  INFO is INTEGER
  Signals processing OK (=0) or failure (=1)
```

SYNOPSIS
   Functions/Subroutines
       subroutine slarrj (N, D, E2, IFIRST, ILAST, RTOL, OFFSET, W, WERR,
           WORK, IWORK, PIVMIN, SPDIAM, INFO)
           SLARRJ performs refinement of the initial estimates of the
           eigenvalues of the matrix T.

Function/Subroutine Documentation
   subroutine slarrj (integer N, real, dimension( * ) D, real, dimension( * )
       E2, integer IFIRST, integer ILAST, real RTOL, integer OFFSET, real,
       dimension( * ) W, real, dimension( * ) WERR, real, dimension( * ) WORK,
       integer, dimension( * ) IWORK, real PIVMIN, real SPDIAM, integer INFO)
       SLARRJ performs refinement of the initial estimates of the eigenvalues
       of the matrix T.

Purpose:
   Given the initial eigenvalue approximations of T, SLARRJ
   does  bisection to refine the eigenvalues of T,
   W( IFIRST-OFFSET ) through W( ILAST-OFFSET ), to more accuracy. Initial
   guesses for these eigenvalues are input in W, the corresponding estimate
   of the error in these guesses in WERR. During bisection, intervals
   [left, right] are maintained by storing their mid-points and
   semi-widths in the arrays W and WERR respectively.

Parameters:

 N
   N is INTEGER
   The order of the matrix.

 D
   D is REAL array, dimension (N)
   The N diagonal elements of T.

 E2
   E2 is REAL array, dimension (N-1)
   The Squares of the (N-1) subdiagonal elements of T.
```

```
IFIRST
  IFIRST is INTEGER
  The index of the first eigenvalue to be computed.

ILAST
  ILAST is INTEGER
  The index of the last eigenvalue to be computed.

RTOL
  RTOL is REAL
  Tolerance for the convergence of the bisection intervals.
  An interval [LEFT,RIGHT] has converged if
  RIGHT-LEFT.LT.RTOL*MAX(|LEFT|,|RIGHT|).

OFFSET
  OFFSET is INTEGER
  Offset for the arrays W and WERR, i.e., the IFIRST-OFFSET
  through ILAST-OFFSET elements of these arrays are to be used.

W
  W is REAL array, dimension (N)
  On input, W( IFIRST-OFFSET ) through W( ILAST-OFFSET ) are
  estimates of the eigenvalues of L D L^T indexed IFIRST through ILAST.
  On output, these estimates are refined.

WERR
  WERR is REAL array, dimension (N)
  On input, WERR( IFIRST-OFFSET ) through WERR( ILAST-OFFSET ) are
  the errors in the estimates of the corresponding elements in W.
  On output, these errors are refined.

WORK
  WORK is REAL array, dimension (2*N)
  Workspace.

IWORK
  IWORK is INTEGER array, dimension (2*N)
  Workspace.

PIVMIN
  PIVMIN is REAL
  The minimum pivot in the Sturm sequence for T.

SPDIAM
  SPDIAM is REAL
  The spectral diameter of T.

INFO
  INFO is INTEGER
```

Error flag.

Man Page Details
======================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slarrk (N, IW, GL, GU, D, E2, PIVMIN, RELTOL, W, WERR, INFO)
           SLARRK computes one eigenvalue of a symmetric tridiagonal matrix T
           to suitable accuracy.

Function/Subroutine Documentation
   subroutine slarrk (integer N, integer IW, real GL, real GU, real,
       dimension( * ) D, real, dimension( * ) E2, real PIVMIN, real RELTOL,
       real W, real WERR, integer INFO)
       SLARRK computes one eigenvalue of a symmetric tridiagonal matrix T to
       suitable accuracy.

Purpose:
   SLARRK computes one eigenvalue of a symmetric tridiagonal
   matrix T to suitable accuracy. This is an auxiliary code to be
```

```
  called from SSTEMR.

  To avoid overflow, the matrix must be scaled so that its
  largest element is no greater than
      overflow**(1/2) * underflow**(1/4)
  in absolute value, and for greatest
  accuracy, it should not be much smaller than that.

Parameters:

N
  N is INTEGER
  The order of the tridiagonal matrix T.  N >= 0.

IW
  IW is INTEGER
  The index of the eigenvalues to be returned.

GL
  GL is REAL

GU
  GU is REAL
  An upper and a lower bound on the eigenvalue.

D
  D is REAL array, dimension (N)
  The n diagonal elements of the tridiagonal matrix T.

E2
  E2 is REAL array, dimension (N-1)
  The (n-1) squared off-diagonal elements of the tridiagonal matrix T.

PIVMIN
  PIVMIN is REAL
  The minimum pivot allowed in the Sturm sequence for T.

RELTOL
  RELTOL is REAL
  The minimum relative width of an interval.  When an interval
  is narrower than RELTOL times the larger (in
  magnitude) endpoint, then it is considered to be
  sufficiently small, i.e., converged.  Note: this should
  always be at least radix*machine epsilon.

W
  W is REAL

WERR
  WERR is REAL
```

```
   The error bound on the corresponding eigenvalue approximation in W.

 INFO
   INFO is INTEGER
   = 0:       Eigenvalue converged
   = -1:      Eigenvalue did NOT converge

Internal Parameters:

 FUDGE   REAL            , default = 2
   A "fudge factor" to widen the Gershgorin intervals.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slarrr (N, D, E, INFO)
           SLARRR performs tests to decide whether the symmetric tridiagonal
           matrix T warrants expensive computations which guarantee high
           relative accuracy in the eigenvalues.

Function/Subroutine Documentation
   subroutine slarrr (integer N, real, dimension( * ) D, real, dimension( * )
       E, integer INFO)
       SLARRR performs tests to decide whether the symmetric tridiagonal
       matrix T warrants expensive computations which guarantee high relative
       accuracy in the eigenvalues.

Purpose:
   Perform tests to decide whether the symmetric tridiagonal matrix T
   warrants expensive computations which guarantee high relative accuracy
   in the eigenvalues.

Parameters:

 N
   N is INTEGER
   The order of the matrix. N > 0.

 D
   D is REAL array, dimension (N)
   The N diagonal elements of the tridiagonal matrix T.
```

```
 E
   E is REAL array, dimension (N)
   On entry, the first (N-1) entries contain the subdiagonal
   elements of the tridiagonal matrix T; E(N) is set to ZERO.

 INFO
   INFO is INTEGER
   INFO = 0(default) : the matrix warrants computations preserving
         relative accuracy.
   INFO = 1 : the matrix warrants computations guaranteeing
         only absolute accuracy.
```

=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slartg (F, G, CS, SN, R)
           SLARTG generates a plane rotation with real cosine and real sine.

Function/Subroutine Documentation
   subroutine slartg (real F, real G, real CS, real SN, real R)
       SLARTG generates a plane rotation with real cosine and real sine.

Purpose:
   SLARTG generate a plane rotation so that

   [  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
   [ -SN  CS  ]     [ G ]     [ 0 ]

   This is a slower, more accurate version of the BLAS1 routine SROTG,
   with the following other differences:
   F and G are unchanged on return.
   If G=0, then CS=1 and SN=0.
     If F=0 and (G .ne. 0), then CS=0 and SN=1 without doing any
     floating point operations (saves work in SBDSQR when
     there are zeros on the diagonal).

   If F exceeds G in magnitude, CS will be positive.

Parameters:

 F
   F is REAL
   The first component of vector to be rotated.

 G
   G is REAL
   The second component of vector to be rotated.

 CS
   CS is REAL
   The cosine of the rotation.

 SN
   SN is REAL
   The sine of the rotation.

 R
```

```
R is REAL
The nonzero component of the rotated vector.

This version has a few statements commented out for thread safety
(machine parameters are computed on each entry). 10 feb 03, SJH.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slartgp (F, G, CS, SN, R)
           SLARTGP generates a plane rotation so that the diagonal is
           nonnegative.

Function/Subroutine Documentation
   subroutine slartgp (real F, real G, real CS, real SN, real R)
       SLARTGP generates a plane rotation so that the diagonal is nonnegative.

Purpose:
   SLARTGP generates a plane rotation so that

   [  CS  SN  ]  .  [ F ]  =  [ R ]   where CS**2 + SN**2 = 1.
   [ -SN  CS  ]     [ G ]     [ 0 ]

   This is a slower, more accurate version of the Level 1 BLAS routine SROTG,
   with the following other differences:
   F and G are unchanged on return.
     If G=0, then CS=(+/-)1 and SN=0.
     If F=0 and (G .ne. 0), then CS=0 and SN=(+/-)1.

   The sign is chosen so that R >= 0.

Parameters:

 F
   F is REAL
   The first component of vector to be rotated.

 G
   G is REAL
   The second component of vector to be rotated.

 CS
   CS is REAL
   The cosine of the rotation.

 SN
   SN is REAL
   The sine of the rotation.

 R
   R is REAL
   The nonzero component of the rotated vector.

   This version has a few statements commented out for thread safety

SYNOPSIS
   Functions/Subroutines
       subroutine slaruv (ISEED, N, X)
           SLARUV returns a vector of n random real numbers from a uniform
           distribution.

Function/Subroutine Documentation
   subroutine slaruv (integer, dimension( 4 ) ISEED, integer N, real,
       dimension( n ) X)
       SLARUV returns a vector of n random real numbers from a uniform
       distribution.

Purpose:
   SLARUV returns a vector of n random real numbers from a uniform (0,1)
   distribution (n <= 128).

   This is an auxiliary routine called by SLARNV and CLARNV.

Parameters:

 ISEED
   ISEED is INTEGER array, dimension (4)
   On entry, the seed of the random number generator; the array
   elements must be between 0 and 4095, and ISEED(4) must be odd.
   On exit, the seed is updated.

 N
   N is INTEGER
   The number of random numbers to be generated. N <= 128.

 X
   X is REAL array, dimension (N)
   The generated random numbers.

Further Details:

   This routine uses a multiplicative congruential method with modulus
   2**48 and multiplier 33952834046453 (see G.S.Fishman,
   'Multiplicative congruential random number generators with modulus
   2**b: an exhaustive analysis for b = 32 and a partial analysis for
   b = 48', Math. Comp. 189, pp 331-344, 1990).

   48-bit integers are stored in 4 integer array elements with 12 bits
   per element. Hence the routine is portable across machines with
   integers of 32 bits or more.
```

*           n bits of the 48-bit integer above happen to be all 1 (which
*           will occur about once every 2**n calls), then X( I ) will
*           be rounded to exactly 1.0. In IEEE single precision arithmetic,
*           this will happen relatively often since n = 24.
*           Since X( I ) is not supposed to return exactly 0.0 or 1.0,
*           the statistically correct thing to do in this situation is
*           simply to iterate again.
*           N.B. the case X( I ) = 0.0 should not be possible.
            I1 = I1 + 2
            I2 = I2 + 2
            I3 = I3 + 2
            I4 = I4 + 2
            GOTO 20
         END IF
*
   10 CONTINUE
*
*     Return final value of seed
*
      ISEED( 1 ) = IT1
```

```
      ISEED( 2 ) = IT2
      ISEED( 3 ) = IT3
      ISEED( 4 ) = IT4
      RETURN

====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slas2 (F, G, H, SSMIN, SSMAX)
           SLAS2 computes singular values of a 2-by-2 triangular matrix.

Function/Subroutine Documentation
   subroutine slas2 (real F, real G, real H, real SSMIN, real SSMAX)
       SLAS2 computes singular values of a 2-by-2 triangular matrix.

Purpose:
   SLAS2  computes the singular values of the 2-by-2 matrix
      [  F   G  ]
      [  0   H  ].
   On return, SSMIN is the smaller singular value and SSMAX is the
   larger singular value.

Parameters:

 F
   F is REAL
   The (1,1) element of the 2-by-2 matrix.

 G
   G is REAL
   The (1,2) element of the 2-by-2 matrix.

 H
   H is REAL
   The (2,2) element of the 2-by-2 matrix.

 SSMIN
   SSMIN is REAL
   The smaller singular value.

 SSMAX
   SSMAX is REAL
   The larger singular value.

Further Details:

   Barring over/underflow, all output quantities are correct to within
   a few units in the last place (ulps), even in the absence of a guard
```

```
digit in addition/subtraction.

In IEEE arithmetic, the code works correctly if one matrix element is
infinite.

Overflow will not occur unless the largest singular value itself
overflows, or is within a few ulps of overflow. (On machines with
partial overflow, like the Cray, overflow may occur if the largest
singular value is within a factor of 2 of overflow.)

Underflow is harmless if underflow is gradual. Otherwise, results
may correspond to a matrix modified by perturbations of size near
the underflow threshold.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slascl (TYPE, KL, KU, CFROM, CTO, M, N, A, LDA, INFO)
           SLASCL multiplies a general rectangular matrix by a real scalar
           defined as cto/cfrom.

Function/Subroutine Documentation
   subroutine slascl (character TYPE, integer KL, integer KU, real CFROM, real
       CTO, integer M, integer N, real, dimension( lda, * ) A, integer LDA,
       integer INFO)
       SLASCL multiplies a general rectangular matrix by a real scalar defined
       as cto/cfrom.

Purpose:
   SLASCL multiplies the M by N real matrix A by the real scalar
   CTO/CFROM.  This is done without over/underflow as long as the final
   result CTO*A(I,J)/CFROM does not over/underflow. TYPE specifies that
   A may be full, upper triangular, lower triangular, upper Hessenberg,
   or banded.

Parameters:

 TYPE
   TYPE is CHARACTER*1
   TYPE indices the storage type of the input matrix.
   = 'G':  A is a full matrix.
   = 'L':  A is a lower triangular matrix.
   = 'U':  A is an upper triangular matrix.
   = 'H':  A is an upper Hessenberg matrix.
   = 'B':  A is a symmetric band matrix with lower bandwidth KL
      and upper bandwidth KU and with the only the lower half stored.
   = 'Q':  A is a symmetric band matrix with lower bandwidth KL
      and upper bandwidth KU and with the only the upper half stored.
   = 'Z':  A is a band matrix with lower bandwidth KL and upper
      bandwidth KU. See SGBTRF for storage details.

 KL
   KL is INTEGER
   The lower bandwidth of A.  Referenced only if TYPE = 'B', 'Q' or 'Z'.

 KU
   KU is INTEGER
```

```
  The upper bandwidth of A.  Referenced only if TYPE = 'B', 'Q' or 'Z'.

CFROM
  CFROM is REAL

CTO
  CTO is REAL

  The matrix A is multiplied by CTO/CFROM. A(I,J) is computed
  without over/underflow if the final result CTO*A(I,J)/CFROM
  can be represented without over/underflow.  CFROM must be nonzero.

M
  M is INTEGER
  The number of rows of the matrix A.  M >= 0.

N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

A
  A is REAL array, dimension (LDA,N)
  The matrix to be multiplied by CTO/CFROM.  See TYPE for the storage type.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

INFO
  INFO is INTEGER
  0  - successful exit
  < 0 - if INFO = -i, the i-th argument had an illegal value.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasd0 (N, SQRE, D, E, U, LDU, VT, LDVT, SMLSIZ, IWORK,
           WORK, INFO)
           SLASD0 computes the singular values of a real upper bidiagonal n-
           by-m matrix B with diagonal d and off-diagonal e. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd0 (integer N, integer SQRE, real, dimension( * ) D, real,
       dimension( * ) E, real, dimension( ldu, * ) U, integer LDU, real,
       dimension( ldvt, * ) VT, integer LDVT, integer SMLSIZ, integer,
       dimension( * ) IWORK, real, dimension( * ) WORK, integer INFO)
       SLASD0 computes the singular values of a real upper bidiagonal n-by-m
       matrix B with diagonal d and off-diagonal e. Used by sbdsdc.

Purpose:
   Using a divide and conquer approach, SLASD0 computes the singular
   value decomposition (SVD) of a real upper bidiagonal N-by-M
   matrix B with diagonal D and offdiagonal E, where M = N + SQRE.
   The algorithm computes orthogonal matrices U and VT such that
   B = U * S * VT. The singular values S are overwritten on D.

   A related subroutine, SLASDA, computes only the singular values,
   and optionally, the singular vectors in compact form.

Parameters:

 N
   N is INTEGER
   On entry, the row dimension of the upper bidiagonal matrix.
   This is also the dimension of the main diagonal array D.

 SQRE
   SQRE is INTEGER
   Specifies the column dimension of the bidiagonal matrix.
   = 0: The bidiagonal matrix has column dimension M = N;
   = 1: The bidiagonal matrix has column dimension M = N+1;

 D
   D is REAL array, dimension (N)
   On entry D contains the main diagonal of the bidiagonal matrix.
   On exit D, if INFO = 0, contains its singular values.

 E
   E is REAL array, dimension (M-1)
   Contains the subdiagonal entries of the bidiagonal matrix.
```

```
  On exit, E has been destroyed.

U
  U is REAL array, dimension at least (LDQ, N)
  On exit, U contains the left singular vectors.

LDU
  LDU is INTEGER
  On entry, leading dimension of U.

VT
  VT is REAL array, dimension at least (LDVT, M)
  On exit, VT**T contains the right singular vectors.

LDVT
  LDVT is INTEGER
  On entry, leading dimension of VT.

SMLSIZ
  SMLSIZ is INTEGER
  On entry, maximum size of the subproblems at the
  bottom of the computation tree.

IWORK
  IWORK is INTEGER array, dimension (8*N)

WORK
  WORK is REAL array, dimension (3*M**2+2*M)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasd1 (NL, NR, SQRE, D, ALPHA, BETA, U, LDU, VT, LDVT,
           IDXQ, IWORK, WORK, INFO)
           SLASD1 computes the SVD of an upper bidiagonal matrix B of the
           specified size. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd1 (integer NL, integer NR, integer SQRE, real, dimension( *
       ) D, real ALPHA, real BETA, real, dimension( ldu, * ) U, integer LDU,
       real, dimension( ldvt, * ) VT, integer LDVT, integer, dimension( * )
       IDXQ, integer, dimension( * ) IWORK, real, dimension( * ) WORK, integer
       INFO)
       SLASD1 computes the SVD of an upper bidiagonal matrix B of the
       specified size. Used by sbdsdc.

Purpose:
   SLASD1 computes the SVD of an upper bidiagonal N-by-M matrix B,
   where N = NL + NR + 1 and M = N + SQRE. SLASD1 is called from SLASD0.

   A related subroutine SLASD7 handles the case in which the singular
   values (and the singular vectors in factored form) are desired.

   SLASD1 computes the SVD as follows:

                         ( D1(in)    0    0       0 )
             B = U(in) * (   Z1**T   a   Z2**T    b ) * VT(in)
                         (   0       0   D2(in)   0 )

               = U(out) * ( D(out) 0) * VT(out)

   where Z**T = (Z1**T a Z2**T b) = u**T VT**T, and u is a vector of
   dimension M with ALPHA and BETA in the NL+1 and NL+2 th
   entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

   The left singular vectors of the original matrix are stored in U, and
   the transpose of the right singular vectors are stored in VT, and the
   singular values are in D.  The algorithm consists of three stages:

   The first stage consists of deflating the size of the problem
   when there are multiple singular values or when there are zeros in
   the Z vector.  For each such occurence the dimension of the
```

```
  secular equation problem is reduced by one.  This stage is
  performed by the routine SLASD2.

  The second stage consists of calculating the updated
  singular values. This is done by finding the square roots of the
  roots of the secular equation via the routine SLASD4 (as called
  by SLASD3). This routine also calculates the singular vectors of
  the current problem.

  The final stage consists of computing the updated singular vectors
  directly using the updated singular values.  The singular vectors
  for the current problem are multiplied with the singular vectors
  from the overall problem.

Parameters:

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has row dimension N = NL + NR + 1,
   and column dimension M = N + SQRE.

 D
   D is REAL array, dimension (NL+NR+1).
   N = NL+NR+1
   On entry D(1:NL,1:NL) contains the singular values of the
   upper block; and D(NL+2:N) contains the singular values of
   the lower block. On exit D(1:N) contains the singular values
   of the modified matrix.

 ALPHA
   ALPHA is REAL
   Contains the diagonal element associated with the added row.

 BETA
   BETA is REAL
   Contains the off-diagonal element associated with the added row.

 U
   U is REAL array, dimension (LDU,N)
```

```
  On entry U(1:NL, 1:NL) contains the left singular vectors of
  the upper block; U(NL+2:N, NL+2:N) contains the left singular
  vectors of the lower block. On exit U contains the left
  singular vectors of the bidiagonal matrix.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= max( 1, N ).

VT
  VT is REAL array, dimension (LDVT,M)
  where M = N + SQRE.
  On entry VT(1:NL+1, 1:NL+1)**T contains the right singular
  vectors of the upper block; VT(NL+2:M, NL+2:M)**T contains
  the right singular vectors of the lower block. On exit
  VT**T contains the right singular vectors of the bidiagonal matrix.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= max( 1, M ).

IDXQ
  IDXQ is INTEGER array, dimension (N)
  This contains the permutation which will reintegrate the
  subproblem just solved back into sorted order, i.e.
  D( IDXQ( I = 1, N ) ) will be in ascending order.

IWORK
  IWORK is INTEGER array, dimension (4*N)

WORK
  WORK is REAL array, dimension (3*M**2+2*M)

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

       dimension( * ) IDXC, integer, dimension( * ) IDXQ, integer, dimension(
       * ) COLTYP, integer INFO)
       SLASD2 merges the two sets of singular values together into a single
       sorted set. Used by sbdsdc.

Purpose:
   SLASD2 merges the two sets of singular values together into a single
   sorted set.  Then it tries to deflate the size of the problem.
   There are two ways in which deflation can occur:  when two or more
   singular values are close together or if there is a tiny entry in the
   Z vector.  For each such occurrence the order of the related secular
   equation problem is reduced by one.

   SLASD2 is called from SLASD1.

Parameters:

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
```

```
  = 0: the lower block is an NR-by-NR square matrix.
  = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

  The bidiagonal matrix has N = NL + NR + 1 rows and
  M = N + SQRE >= N columns.

K
  K is INTEGER
  Contains the dimension of the non-deflated matrix,
  This is the order of the related secular equation. 1 <= K <=N.

D
  D is REAL array, dimension (N)
  On entry D contains the singular values of the two submatrices
  to be combined.  On exit D contains the trailing (N-K) updated
  singular values (those which were deflated) sorted into increasing order.

Z
  Z is REAL array, dimension (N)
  On exit Z contains the updating row vector in the secular equation.

ALPHA
  ALPHA is REAL
  Contains the diagonal element associated with the added row.

BETA
  BETA is REAL
  Contains the off-diagonal element associated with the added row.

U
  U is REAL array, dimension (LDU,N)
  On entry U contains the left singular vectors of two
  submatrices in the two square blocks with corners at (1,1),
  (NL, NL), and (NL+2, NL+2), (N,N).
  On exit U contains the trailing (N-K) updated left singular
  vectors (those which were deflated) in its last N-K columns.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= N.

VT
  VT is REAL array, dimension (LDVT,M)
  On entry VT**T contains the right singular vectors of two
  submatrices in the two square blocks with corners at (1,1),
  (NL+1, NL+1), and (NL+2, NL+2), (M,M).
  On exit VT**T contains the trailing (N-K) updated right singular
  vectors (those which were deflated) in its last N-K columns.
  In case SQRE =1, the last row of VT spans the right null space.
```

```
LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= M.

DSIGMA
  DSIGMA is REAL array, dimension (N)
  Contains a copy of the diagonal elements (K-1 singular values
  and one zero) in the secular equation.

U2
  U2 is REAL array, dimension (LDU2,N)
  Contains a copy of the first K-1 left singular vectors which
  will be used by SLASD3 in a matrix multiply (SGEMM) to solve
  for the new left singular vectors. U2 is arranged into four
  blocks. The first block contains a column with 1 at NL+1 and
  zero everywhere else; the second block contains non-zero
  entries only at and above NL; the third contains non-zero
  entries only below NL+1; and the fourth is dense.

LDU2
  LDU2 is INTEGER
  The leading dimension of the array U2.  LDU2 >= N.

VT2
  VT2 is REAL array, dimension (LDVT2,N)
  VT2**T contains a copy of the first K right singular vectors
  which will be used by SLASD3 in a matrix multiply (SGEMM) to
  solve for the new right singular vectors. VT2 is arranged into
  three blocks. The first block contains a row that corresponds
  to the special 0 diagonal element in SIGMA; the second block
  contains non-zeros only at and before NL +1; the third block
  contains non-zeros only at and after  NL +2.

LDVT2
  LDVT2 is INTEGER
  The leading dimension of the array VT2.  LDVT2 >= M.

IDXP
  IDXP is INTEGER array, dimension (N)
  This will contain the permutation used to place deflated
  values of D at the end of the array. On output IDXP(2:K)
  points to the nondeflated D-values and IDXP(K+1:N)
  points to the deflated singular values.

IDX
  IDX is INTEGER array, dimension (N)
  This will contain the permutation used to sort the contents of
  D into ascending order.

IDXC
```

```
  IDXC is INTEGER array, dimension (N)
  This will contain the permutation used to arrange the columns
  of the deflated U matrix into three groups:  the first group
  contains non-zero entries only at and above NL, the second
  contains non-zero entries only below NL+2, and the third is dense.

IDXQ
  IDXQ is INTEGER array, dimension (N)
  This contains the permutation which separately sorts the two
  sub-problems in D into ascending order.  Note that entries in
  the first hlaf of this permutation must first be moved one
  position backward; and entries in the second half
  must first have NL+1 added to their values.

COLTYP
  COLTYP is INTEGER array, dimension (N)
  As workspace, this will contain a label which will indicate
  which of the following types a column in the U2 matrix or a
  row in the VT2 matrix is:
  1 : non-zero in the upper half only
  2 : non-zero in the lower half only
  3 : dense
  4 : deflated

  On exit, it is an array of dimension 4, with COLTYP(I) being
  the dimension of the I-th type columns.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

*
*     There are 2 kinds of deflation -- first a value in the z-vector
*     is small, second two (or more) singular values are very close
*     together (their difference is small).
*
*     If the value in the z-vector is small, we simply permute the
*     array so that the corresponding singular value is moved to the
*     end.
*
*     If two values in the D-vector are close, we perform a two-sided
*     rotation designed to make one of the corresponding z-vector
*     entries zero, and then permute the array so that the deflated
*     singular value is moved to the end.
*
*     If there are multiple singular values then the problem deflates.
*     Here the number of equal singular values are found.  As each equal
*     singular value is found, an elementary reflector is computed to
*     rotate the corresponding singular subspace so that the
*     corresponding components of Z are zero in this new basis.

SYNOPSIS
   Functions/Subroutines
       subroutine slasd3 (NL, NR, SQRE, K, D, Q, LDQ, DSIGMA, U, LDU, U2,
           LDU2, VT, LDVT, VT2, LDVT2, IDXC, CTOT, Z, INFO)
           SLASD3 finds all square roots of the roots of the secular equation,
```

```
          as defined by the values in D and Z, and then updates the singular
          vectors by matrix multiplication. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd3 (integer NL, integer NR, integer SQRE, integer K, real,
       dimension( * ) D, real, dimension( ldq, * ) Q, integer LDQ, real,
       dimension( * ) DSIGMA, real, dimension( ldu, * ) U, integer LDU, real,
       dimension( ldu2, * ) U2, integer LDU2, real, dimension( ldvt, * ) VT,
       integer LDVT, real, dimension( ldvt2, * ) VT2, integer LDVT2, integer,
       dimension( * ) IDXC, integer, dimension( * ) CTOT, real, dimension( * )
       Z, integer INFO)
       SLASD3 finds all square roots of the roots of the secular equation, as
       defined by the values in D and Z, and then updates the singular vectors
       by matrix multiplication. Used by sbdsdc.

Purpose:
   SLASD3 finds all the square roots of the roots of the secular
   equation, as defined by the values in D and Z.  It makes the
   appropriate calls to SLASD4 and then updates the singular
   vectors by matrix multiplication.

   This code makes very mild assumptions about floating point
   arithmetic. It will work on machines with a guard digit in
   add/subtract, or on those binary machines without guard digits
   which subtract like the Cray XMP, Cray YMP, Cray C 90, or Cray 2.
   It could conceivably fail on hexadecimal or decimal machines
   without guard digits, but we know of none.

   SLASD3 is called from SLASD1.

Parameters:

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has N = NL + NR + 1 rows and
   M = N + SQRE >= N columns.

 K
   K is INTEGER
```

```
  The size of the secular equation, 1 =< K = < N.

D
  D is REAL array, dimension(K)
  On exit the square roots of the roots of the secular equation,
  in ascending order.

Q
  Q is REAL array, dimension at least (LDQ,K).

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.  LDQ >= K.

DSIGMA
  DSIGMA is REAL array, dimension(K)
  The first K elements of this array contain the old roots
  of the deflated updating problem.  These are the poles
  of the secular equation.

U
  U is REAL array, dimension (LDU, N)
  The last N - K columns of this matrix contain the deflated
  left singular vectors.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= N.

U2
  U2 is REAL array, dimension (LDU2, N)
  The first K columns of this matrix contain the non-deflated
  left singular vectors for the split problem.

LDU2
  LDU2 is INTEGER
  The leading dimension of the array U2.  LDU2 >= N.

VT
  VT is REAL array, dimension (LDVT, M)
  The last M - K columns of VT**T contain the deflated
  right singular vectors.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.  LDVT >= N.

VT2
  VT2 is REAL array, dimension (LDVT2, N)
  The first K columns of VT2**T contain the non-deflated
```

```
  right singular vectors for the split problem.

LDVT2
  LDVT2 is INTEGER
  The leading dimension of the array VT2.  LDVT2 >= N.

IDXC
  IDXC is INTEGER array, dimension (N)
  The permutation used to arrange the columns of U (and rows of
  VT) into three groups:  the first group contains non-zero
  entries only at and above (or before) NL +1; the second
  contains non-zero entries only at and below (or after) NL+2;
  and the third is dense. The first column of U and the row of
  VT are treated separately, however.

  The rows of the singular vectors found by SLASD4
  must be likewise permuted before the matrix multiplies can take place.

CTOT
  CTOT is INTEGER array, dimension (4)
  A count of the total number of the various types of columns
  in U (or rows in VT), as described in IDXC. The fourth column
  type is any column which has been deflated.

Z
  Z is REAL array, dimension (K)
  The first K elements of this array contain the components
  of the deflation-adjusted updating row vector.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasd4 (N, I, D, Z, DELTA, RHO, SIGMA, WORK, INFO)
           SLASD4 computes the square root of the i-th updated eigenvalue of a
           positive symmetric rank-one modification to a positive diagonal
           matrix. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd4 (integer N, integer I, real, dimension( * ) D, real,
       dimension( * ) Z, real, dimension( * ) DELTA, real RHO, real SIGMA,
       real, dimension( * ) WORK, integer INFO)
       SLASD4 computes the square root of the i-th updated eigenvalue of a
       positive symmetric rank-one modification to a positive diagonal matrix.
       Used by sbdsdc.

Purpose:
```

```
  This subroutine computes the square root of the I-th updated
  eigenvalue of a positive symmetric rank-one modification to
  a positive diagonal matrix whose entries are given as the squares
  of the corresponding entries in the array d, and that

                 0 <= D(i) < D(j)  for  i < j

  and that RHO > 0. This is arranged by the calling routine, and is
  no loss in generality.  The rank-one modified system is thus

                 diag( D ) * diag( D ) +  RHO * Z * Z_transpose.

  where we assume the Euclidean norm of Z is 1.

  The method consists of approximating the rational functions in the
  secular equation by simpler interpolating rational functions.

Parameters:

 N
   N is INTEGER
   The length of all arrays.

 I
   I is INTEGER
   The index of the eigenvalue to be computed.  1 <= I <= N.

 D
   D is REAL array, dimension ( N )
   The original eigenvalues.  It is assumed that they are in
   order, 0 <= D(I) < D(J)  for I < J.

 Z
   Z is REAL array, dimension ( N )
   The components of the updating vector.

 DELTA
   DELTA is REAL array, dimension ( N )
   If N .ne. 1, DELTA contains (D(j) - sigma_I) in its  j-th
   component.  If N = 1, then DELTA(1) = 1.  The vector DELTA
   contains the information necessary to construct the
   (singular) eigenvectors.

 RHO
   RHO is REAL
   The scalar in the symmetric updating formula.

 SIGMA
   SIGMA is REAL
   The computed sigma_I, the I-th updated eigenvalue.
```

```
 WORK
   WORK is REAL array, dimension ( N )
   If N .ne. 1, WORK contains (D(j) + sigma_I) in its  j-th
   component.  If N = 1, then WORK( 1 ) = 1.

 INFO
   INFO is INTEGER
   = 0:  successful exit
   > 0:  if INFO = 1, the updating process failed.

Internal Parameters:

   Logical variable ORGATI (origin-at-i?) is used for distinguishing
   whether D(i) or D(i+1) is treated as the origin.

                      ORGATI = .true.    origin at i
                      ORGATI = .false.   origin at i+1

   Logical variable SWTCH3 (switch-for-3-poles?) is for noting
   if we are working with THREE poles!

   MAXIT is the maximum number of iterations allowed for each
   eigenvalue.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasd5 (I, D, Z, DELTA, RHO, DSIGMA, WORK)
           SLASD5 computes the square root of the i-th eigenvalue of a
           positive symmetric rank-one modification of a 2-by-2 diagonal
           matrix. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd5 (integer I, real, dimension( 2 ) D, real, dimension( 2 )
       Z, real, dimension( 2 ) DELTA, real RHO, real DSIGMA, real, dimension(
       2 ) WORK)
       SLASD5 computes the square root of the i-th eigenvalue of a positive
       symmetric rank-one modification of a 2-by-2 diagonal matrix. Used by
       sbdsdc.

Purpose:
   This subroutine computes the square root of the I-th eigenvalue
   of a positive symmetric rank-one modification of a 2-by-2 diagonal
   matrix

                       diag( D ) * diag( D ) +  RHO * Z * transpose(Z) .

   The diagonal entries in the array D are assumed to satisfy
```

```
                     0 <= D(i) < D(j)  for  i < j .

   We also assume RHO > 0 and that the Euclidean norm of the vector Z is one.

Parameters:

 I
   I is INTEGER
   The index of the eigenvalue to be computed.  I = 1 or I = 2.

 D
   D is REAL array, dimension (2)
   The original eigenvalues.  We assume 0 <= D(1) < D(2).

 Z
   Z is REAL array, dimension (2)
   The components of the updating vector.

 DELTA
   DELTA is REAL array, dimension (2)
   Contains (D(j) - sigma_I) in its  j-th component.
   The vector DELTA contains the information necessary
   to construct the eigenvectors.

 RHO
   RHO is REAL
   The scalar in the symmetric updating formula.

 DSIGMA
   DSIGMA is REAL
   The computed sigma_I, the I-th updated eigenvalue.

 WORK
   WORK is REAL array, dimension (2)
   WORK contains (D(j) + sigma_I) in its  j-th component.
```

    SLASD6 computes the SVD of an updated upper bidiagonal matrix obtained
    by merging two smaller ones by appending a row. Used by sbdsdc.
```

Purpose:

```
SLASD6 computes the SVD of an updated upper bidiagonal matrix B
obtained by merging two smaller ones by appending a row. This
routine is used only for the problem which requires all singular
values and optionally singular vector matrices in factored form.
B is an N-by-M matrix with N = NL + NR + 1 and M = N + SQRE.
A related subroutine, SLASD1, handles the case in which all singular
values and singular vectors of the bidiagonal matrix are desired.

SLASD6 computes the SVD as follows:

                        ( D1(in)    0    0       0 )
            B = U(in) * (   Z1**T   a   Z2**T    b ) * VT(in)
                        (   0       0   D2(in)   0 )

              = U(out) * ( D(out) 0) * VT(out)

where Z**T = (Z1**T a Z2**T b) = u**T VT**T, and u is a vector of
dimension M with ALPHA and BETA in the NL+1 and NL+2 th
entries and zeros elsewhere; and the entry b is empty if SQRE = 0.

The singular values of B can be computed using D1, D2, the first
components of all the right singular vectors of the lower block, and
the last components of all the right singular vectors of the upper
block. These components are stored and updated in VF and VL,
respectively, in SLASD6. Hence U and VT are not explicitly
referenced.

The singular values are stored in D. The algorithm consists of two
stages:
```

```
  The first stage consists of deflating the size of the problem
  when there are multiple singular values or if there is a zero
  in the Z vector. For each such occurence the dimension of the
  secular equation problem is reduced by one. This stage is
  performed by the routine SLASD7.

  The second stage consists of calculating the updated
  singular values. This is done by finding the roots of the
  secular equation via the routine SLASD4 (as called by SLASD8).
  This routine also updates VF and VL and computes the distances
  between the updated singular values and the old singular
  values.

  SLASD6 is called from SLASDA.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed in
   factored form:
   = 0: Compute singular values only.
   = 1: Compute singular vectors in factored form as well.

 NL
   NL is INTEGER
   The row dimension of the upper block.  NL >= 1.

 NR
   NR is INTEGER
   The row dimension of the lower block.  NR >= 1.

 SQRE
   SQRE is INTEGER
   = 0: the lower block is an NR-by-NR square matrix.
   = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

   The bidiagonal matrix has row dimension N = NL + NR + 1,
   and column dimension M = N + SQRE.

 D
   D is REAL array, dimension (NL+NR+1).
   On entry D(1:NL,1:NL) contains the singular values of the
   upper block, and D(NL+2:N) contains the singular values
   of the lower block. On exit D(1:N) contains the singular
   values of the modified matrix.

 VF
   VF is REAL array, dimension (M)
```

```
  On entry, VF(1:NL+1) contains the first components of all
  right singular vectors of the upper block; and VF(NL+2:M)
  contains the first components of all right singular vectors
  of the lower block. On exit, VF contains the first components
  of all right singular vectors of the bidiagonal matrix.

VL
  VL is REAL array, dimension (M)
  On entry, VL(1:NL+1) contains the  last components of all
  right singular vectors of the upper block; and VL(NL+2:M)
  contains the last components of all right singular vectors of
  the lower block. On exit, VL contains the last components of
  all right singular vectors of the bidiagonal matrix.

ALPHA
  ALPHA is REAL
  Contains the diagonal element associated with the added row.

BETA
  BETA is REAL
  Contains the off-diagonal element associated with the added row.

IDXQ
  IDXQ is INTEGER array, dimension (N)
  This contains the permutation which will reintegrate the
  subproblem just solved back into sorted order, i.e.
  D( IDXQ( I = 1, N ) ) will be in ascending order.

PERM
  PERM is INTEGER array, dimension ( N )
  The permutations (from deflation and sorting) to be applied
  to each block. Not referenced if ICOMPQ = 0.

GIVPTR
  GIVPTR is INTEGER
  The number of Givens rotations which took place in this
  subproblem. Not referenced if ICOMPQ = 0.

GIVCOL
  GIVCOL is INTEGER array, dimension ( LDGCOL, 2 )
  Each pair of numbers indicates a pair of columns to take place
  in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL
  LDGCOL is INTEGER
  leading dimension of GIVCOL, must be at least N.

GIVNUM
  GIVNUM is REAL array, dimension ( LDGNUM, 2 )
  Each number indicates the C or S value to be used in the
```

```
  corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM
  LDGNUM is INTEGER
  The leading dimension of GIVNUM and POLES, must be at least N.

POLES
  POLES is REAL array, dimension ( LDGNUM, 2 )
  On exit, POLES(1,*) is an array containing the new singular
  values obtained from solving the secular equation, and
  POLES(2,*) is an array containing the poles in the secular
  equation. Not referenced if ICOMPQ = 0.

DIFL
  DIFL is REAL array, dimension ( N )
  On exit, DIFL(I) is the distance between I-th updated
  (undeflated) singular value and the I-th (undeflated) old singular value.

DIFR
  DIFR is REAL array,
     dimension ( LDGNUM, 2 ) if ICOMPQ = 1 and
     dimension ( N ) if ICOMPQ = 0.
  On exit, DIFR(I, 1) is the distance between I-th updated
  (undeflated) singular value and the I+1-th (undeflated) old singular value.

  If ICOMPQ = 1, DIFR(1:K,2) is an array containing the
  normalizing factors for the right singular vector matrix.

  See SLASD8 for details on DIFL and DIFR.

Z
  Z is REAL array, dimension ( M )
  The first elements of this array contain the components
  of the deflation-adjusted updating row vector.

K
  K is INTEGER
  Contains the dimension of the non-deflated matrix,
  This is the order of the related secular equation. 1 <= K <=N.

C
  C is REAL
  C contains garbage if SQRE =0 and the C-value of a Givens
  rotation related to the right null space if SQRE = 1.

S
  S is REAL
  S contains garbage if SQRE =0 and the S-value of a Givens
  rotation related to the right null space if SQRE = 1.
```

```
 WORK
   WORK is REAL array, dimension ( 4 * M )

 IWORK
   IWORK is INTEGER array, dimension ( 3 * N )

 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasd7 (ICOMPQ, NL, NR, SQRE, K, D, Z, ZW, VF, VFW, VL, VLW,
           ALPHA, BETA, DSIGMA, IDX, IDXP, IDXQ, PERM, GIVPTR, GIVCOL, LDGCOL,
           GIVNUM, LDGNUM, C, S, INFO)
           SLASD7 merges the two sets of singular values together into a
           single sorted set. Then it tries to deflate the size of the
           problem. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd7 (integer ICOMPQ, integer NL, integer NR, integer SQRE,
       integer K, real, dimension( * ) D, real, dimension( * ) Z, real,
       dimension( * ) ZW, real, dimension( * ) VF, real, dimension( * ) VFW,
       real, dimension( * ) VL, real, dimension( * ) VLW, real ALPHA, real
       BETA, real, dimension( * ) DSIGMA, integer, dimension( * ) IDX,
       integer, dimension( * ) IDXP, integer, dimension( * ) IDXQ, integer,
       dimension( * ) PERM, integer GIVPTR, integer, dimension( ldgcol, * )
       GIVCOL, integer LDGCOL, real, dimension( ldgnum, * ) GIVNUM, integer
       LDGNUM, real C, real S, integer INFO)
       SLASD7 merges the two sets of singular values together into a single
       sorted set. Then it tries to deflate the size of the problem. Used by
       sbdsdc.

Purpose:
   SLASD7 merges the two sets of singular values together into a single
   sorted set. Then it tries to deflate the size of the problem. There
   are two ways in which deflation can occur:  when two or more singular
   values are close together or if there is a tiny entry in the Z
   vector. For each such occurrence the order of the related
   secular equation problem is reduced by one.

   SLASD7 is called from SLASD6.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
```

```
  Specifies whether singular vectors are to be computed
  in compact form, as follows:
  = 0: Compute singular values only.
  = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

NL
  NL is INTEGER
  The row dimension of the upper block. NL >= 1.

NR
  NR is INTEGER
  The row dimension of the lower block. NR >= 1.

SQRE
  SQRE is INTEGER
  = 0: the lower block is an NR-by-NR square matrix.
  = 1: the lower block is an NR-by-(NR+1) rectangular matrix.

  The bidiagonal matrix has
  N = NL + NR + 1 rows and
  M = N + SQRE >= N columns.

K
  K is INTEGER
  Contains the dimension of the non-deflated matrix, this is
  the order of the related secular equation. 1 <= K <=N.

D
  D is REAL array, dimension ( N )
  On entry D contains the singular values of the two submatrices
  to be combined. On exit D contains the trailing (N-K) updated
  singular values (those which were deflated) sorted into increasing order.

Z
  Z is REAL array, dimension ( M )
  On exit Z contains the updating row vector in the secular equation.

ZW
  ZW is REAL array, dimension ( M )
  Workspace for Z.

VF
  VF is REAL array, dimension ( M )
  On entry, VF(1:NL+1) contains the first components of all
  right singular vectors of the upper block; and VF(NL+2:M)
  contains the first components of all right singular vectors
  of the lower block. On exit, VF contains the first components
  of all right singular vectors of the bidiagonal matrix.

VFW
```

```
  VFW is REAL array, dimension ( M )
  Workspace for VF.

VL
  VL is REAL array, dimension ( M )
  On entry, VL(1:NL+1) contains the  last components of all
  right singular vectors of the upper block; and VL(NL+2:M)
  contains the last components of all right singular vectors
  of the lower block. On exit, VL contains the last components
  of all right singular vectors of the bidiagonal matrix.

VLW
  VLW is REAL array, dimension ( M )
  Workspace for VL.

ALPHA
  ALPHA is REAL
  Contains the diagonal element associated with the added row.

BETA
  BETA is REAL
  Contains the off-diagonal element associated with the added row.

DSIGMA
  DSIGMA is REAL array, dimension ( N )
  Contains a copy of the diagonal elements (K-1 singular values
  and one zero) in the secular equation.

IDX
  IDX is INTEGER array, dimension ( N )
  This will contain the permutation used to sort the contents of
  D into ascending order.

IDXP
  IDXP is INTEGER array, dimension ( N )
  This will contain the permutation used to place deflated
  values of D at the end of the array. On output IDXP(2:K)
  points to the nondeflated D-values and IDXP(K+1:N)
  points to the deflated singular values.

IDXQ
  IDXQ is INTEGER array, dimension ( N )
  This contains the permutation which separately sorts the two
  sub-problems in D into ascending order.  Note that entries in
  the first half of this permutation must first be moved one
  position backward; and entries in the second half
  must first have NL+1 added to their values.

PERM
  PERM is INTEGER array, dimension ( N )
```

```
  The permutations (from deflation and sorting) to be applied
  to each singular block. Not referenced if ICOMPQ = 0.

GIVPTR
  GIVPTR is INTEGER
  The number of Givens rotations which took place in this
  subproblem. Not referenced if ICOMPQ = 0.

GIVCOL
  GIVCOL is INTEGER array, dimension ( LDGCOL, 2 )
  Each pair of numbers indicates a pair of columns to take place
  in a Givens rotation. Not referenced if ICOMPQ = 0.

LDGCOL
  LDGCOL is INTEGER
  The leading dimension of GIVCOL, must be at least N.

GIVNUM
  GIVNUM is REAL array, dimension ( LDGNUM, 2 )
  Each number indicates the C or S value to be used in the
  corresponding Givens rotation. Not referenced if ICOMPQ = 0.

LDGNUM
  LDGNUM is INTEGER
  The leading dimension of GIVNUM, must be at least N.

C
  C is REAL
  C contains garbage if SQRE =0 and the C-value of a Givens
  rotation related to the right null space if SQRE = 1.

S
  S is REAL
  S contains garbage if SQRE =0 and the S-value of a Givens
  rotation related to the right null space if SQRE = 1.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.

      TOL = EIGHT*EIGHT*EPS*MAX( ABS( D( N ) ), TOL )
*
*     There are 2 kinds of deflation -- first a value in the z-vector
*     is small, second two (or more) singular values are very close
*     together (their difference is small).
*
*     If the value in the z-vector is small, we simply permute the
*     array so that the corresponding singular value is moved to the
*     end.
*
*     If two values in the D-vector are close, we perform a two-sided
*     rotation designed to make one of the corresponding z-vector
*     entries zero, and then permute the array so that the deflated
*     singular value is moved to the end.
*
*     If there are multiple singular values then the problem deflates.
*     Here the number of equal singular values are found.  As each equal
*     singular value is found, an elementary reflector is computed to
*     rotate the corresponding singular subspace so that the
*     corresponding components of Z are zero in this new basis.

SYNOPSIS
   Functions/Subroutines
       subroutine slasd8 (ICOMPQ, K, D, Z, VF, VL, DIFL, DIFR, LDDIFR, DSIGMA,
           WORK, INFO)
           SLASD8 finds the square roots of the roots of the secular equation,
           and stores, for each element in D, the distance to its two nearest
           poles. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasd8 (integer ICOMPQ, integer K, real, dimension( * ) D, real,
       dimension( * ) Z, real, dimension( * ) VF, real, dimension( * ) VL,
       real, dimension( * ) DIFL, real, dimension( lddifr, * ) DIFR, integer
```

```
      LDDIFR, real, dimension( * ) DSIGMA, real, dimension( * ) WORK, integer
      INFO)
      SLASD8 finds the square roots of the roots of the secular equation, and
      stores, for each element in D, the distance to its two nearest poles.
      Used by sbdsdc.

Purpose:
   SLASD8 finds the square roots of the roots of the secular equation,
   as defined by the values in DSIGMA and Z. It makes the appropriate
   calls to SLASD4, and stores, for each  element in D, the distance
   to its two nearest poles (elements in DSIGMA). It also updates
   the arrays VF and VL, the first and last components of all the
   right singular vectors of the original bidiagonal matrix.

   SLASD8 is called from SLASD6.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed in
   factored form in the calling routine:
   = 0: Compute singular values only.
   = 1: Compute singular vectors in factored form as well.

 K
   K is INTEGER
   The number of terms in the rational function to be solved
   by SLASD4.  K >= 1.

 D
   D is REAL array, dimension ( K )
   On output, D contains the updated singular values.

 Z
   Z is REAL array, dimension ( K )
   On entry, the first K elements of this array contain the
   components of the deflation-adjusted updating row vector.
   On exit, Z is updated.

 VF
   VF is REAL array, dimension ( K )
   On entry, VF contains  information passed through DBEDE8.
   On exit, VF contains the first K components of the first
   components of all right singular vectors of the bidiagonal matrix.

 VL
   VL is REAL array, dimension ( K )
   On entry, VL contains  information passed through DBEDE8.
   On exit, VL contains the first K components of the last
```

```
  components of all right singular vectors of the bidiagonal matrix.

 DIFL
   DIFL is REAL array, dimension ( K )
   On exit, DIFL(I) = D(I) - DSIGMA(I).

 DIFR
   DIFR is REAL array,
      dimension ( LDDIFR, 2 ) if ICOMPQ = 1 and
      dimension ( K ) if ICOMPQ = 0.
   On exit, DIFR(I,1) = D(I) - DSIGMA(I+1), DIFR(K,1) is not
   defined and will not be referenced.

   If ICOMPQ = 1, DIFR(1:K,2) is an array containing the
   normalizing factors for the right singular vector matrix.

 LDDIFR
   LDDIFR is INTEGER
   The leading dimension of DIFR, must be at least K.

 DSIGMA
   DSIGMA is REAL array, dimension ( K )
   On entry, the first K elements of this array contain the old
   roots of the deflated updating problem.  These are the poles
   of the secular equation.
   On exit, the elements of DSIGMA may be very slightly altered in value.

 WORK
   WORK is REAL array, dimension at least 3 * K

 INFO
   INFO is INTEGER
   = 0:  successful exit.
   < 0:  if INFO = -i, the i-th argument had an illegal value.
   > 0:  if INFO = 1, a singular value did not converge
```

*     This is a problem on machines without a guard digit in
*     add/subtract (Cray XMP, Cray YMP, Cray C 90 and Cray 2).
*     The following code replaces DSIGMA(I) by 2*DSIGMA(I)-DSIGMA(I),
*     which on any of these machines zeros out the bottommost
*     bit of DSIGMA(I) if it is 1; this makes the subsequent
*     subtractions DSIGMA(I)-DSIGMA(J) unproblematic when cancellation
*     occurs. On binary machines with a guard digit (almost all
*     machines) it does not change DSIGMA(I) at all. On hexadecimal
*     and decimal machines with a guard digit, it slightly
*     changes the bottommost bits of DSIGMA(I). It does not account
*     for hexadecimal or decimal machines without guard digits
*     (we know of none). We use a subroutine call to compute
*     2*DLAMBDA(I) to prevent optimizing compilers from eliminating
*     this code.
*

SYNOPSIS
```

```
   Functions/Subroutines
       subroutine slasda (ICOMPQ, SMLSIZ, N, SQRE, D, E, U, LDU, VT, K, DIFL,
           DIFR, Z, POLES, GIVPTR, GIVCOL, LDGCOL, PERM, GIVNUM, C, S, WORK,
           IWORK, INFO)
           SLASDA computes the singular value decomposition (SVD) of a real
           upper bidiagonal matrix with diagonal d and off-diagonal e. Used by
           sbdsdc.

Function/Subroutine Documentation
   subroutine slasda (integer ICOMPQ, integer SMLSIZ, integer N, integer SQRE,
       real, dimension( * ) D, real, dimension( * ) E, real, dimension( ldu, *
       ) U, integer LDU, real, dimension( ldu, * ) VT, integer, dimension( * )
       K, real, dimension( ldu, * ) DIFL, real, dimension( ldu, * ) DIFR,

       GIVNUM, real, dimension( * ) C, real, dimension( * ) S, real,
       dimension( * ) WORK, integer, dimension( * ) IWORK, integer INFO)
       SLASDA computes the singular value decomposition (SVD) of a real upper
       bidiagonal matrix with diagonal d and off-diagonal e. Used by sbdsdc.

Purpose:
   Using a divide and conquer approach, SLASDA computes the singular
   value decomposition (SVD) of a real upper bidiagonal N-by-M matrix
   B with diagonal D and offdiagonal E, where M = N + SQRE. The
   algorithm computes the singular values in the SVD B = U * S * VT.
   The orthogonal matrices U and VT are optionally computed in
   compact form.

   A related subroutine, SLASD0, computes the singular values and
   the singular vectors in explicit form.

Parameters:

 ICOMPQ
   ICOMPQ is INTEGER
   Specifies whether singular vectors are to be computed
   in compact form, as follows
   = 0: Compute singular values only.
   = 1: Compute singular vectors of upper bidiagonal matrix in compact form.

 SMLSIZ
   SMLSIZ is INTEGER
   The maximum size of the subproblems at the bottom of the computation tree.

 N
   N is INTEGER
   The row dimension of the upper bidiagonal matrix. This is
   also the dimension of the main diagonal array D.
```

```
SQRE
  SQRE is INTEGER
  Specifies the column dimension of the bidiagonal matrix.
  = 0: The bidiagonal matrix has column dimension M = N;
  = 1: The bidiagonal matrix has column dimension M = N + 1.

D
  D is REAL array, dimension ( N )
  On entry D contains the main diagonal of the bidiagonal
  matrix. On exit D, if INFO = 0, contains its singular values.

E
  E is REAL array, dimension ( M-1 )
  Contains the subdiagonal entries of the bidiagonal matrix.
  On exit, E has been destroyed.

U
  U is REAL array,
  dimension ( LDU, SMLSIZ ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, U contains the left
  singular vector matrices of all subproblems at the bottom level.

LDU
  LDU is INTEGER, LDU = > N.
  The leading dimension of arrays U, VT, DIFL, DIFR, POLES, GIVNUM, and Z.

VT
  VT is REAL array,
  dimension ( LDU, SMLSIZ+1 ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, VT**T contains the right
  singular vector matrices of all subproblems at the bottom level.

K
  K is INTEGER array, dimension ( N )
  if ICOMPQ = 1 and dimension 1 if ICOMPQ = 0.
  If ICOMPQ = 1, on exit, K(I) is the dimension of the I-th
  secular equation on the computation tree.

DIFL
  DIFL is REAL array, dimension ( LDU, NLVL ),
  where NLVL = floor(log_2 (N/SMLSIZ))).

DIFR
  DIFR is REAL array,
     dimension ( LDU, 2 * NLVL ) if ICOMPQ = 1 and
     dimension ( N ) if ICOMPQ = 0.
  If ICOMPQ = 1, on exit, DIFL(1:N, I) and DIFR(1:N, 2 * I - 1)
  record distances between singular values on the I-th
  level and singular values on the (I -1)-th level, and
  DIFR(1:N, 2 * I ) contains the normalizing factors for
```

```
  the right singular vector matrix. See SLASD8 for details.

Z
  Z is REAL array,
     dimension ( LDU, NLVL ) if ICOMPQ = 1 and
     dimension ( N ) if ICOMPQ = 0.
  The first K elements of Z(1, I) contain the components of
  the deflation-adjusted updating row vector for subproblems
  on the I-th level.

POLES
  POLES is REAL array,
  dimension ( LDU, 2 * NLVL ) if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, POLES(1, 2*I - 1) and
  POLES(1, 2*I) contain  the new and old singular values
  involved in the secular equations on the I-th level.

GIVPTR
  GIVPTR is INTEGER array,
  dimension ( N ) if ICOMPQ = 1, and not referenced if
  ICOMPQ = 0. If ICOMPQ = 1, on exit, GIVPTR( I ) records
  the number of Givens rotations performed on the I-th
  problem on the computation tree.

GIVCOL
  GIVCOL is INTEGER array,
  dimension ( LDGCOL, 2 * NLVL ) if ICOMPQ = 1, and not
  referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I,
  GIVCOL(1, 2 *I - 1) and GIVCOL(1, 2 *I) record the locations
  of Givens rotations performed on the I-th level on the computation tree.

LDGCOL
  LDGCOL is INTEGER, LDGCOL = > N.
  The leading dimension of arrays GIVCOL and PERM.

PERM
  PERM is INTEGER array, dimension ( LDGCOL, NLVL )
  if ICOMPQ = 1, and not referenced
  if ICOMPQ = 0. If ICOMPQ = 1, on exit, PERM(1, I) records
  permutations done on the I-th level of the computation tree.

GIVNUM
  GIVNUM is REAL array,
  dimension ( LDU,  2 * NLVL ) if ICOMPQ = 1, and not
  referenced if ICOMPQ = 0. If ICOMPQ = 1, on exit, for each I,
  GIVNUM(1, 2 *I - 1) and GIVNUM(1, 2 *I) record the C- and S-
  values of Givens rotations performed on the I-th level on
  the computation tree.

C
```

```
  C is REAL array,
  dimension ( N ) if ICOMPQ = 1, and dimension 1 if ICOMPQ = 0.
  If ICOMPQ = 1 and the I-th subproblem is not square, on exit,
  C( I ) contains the C-value of a Givens rotation related to
  the right null space of the I-th subproblem.

S
  S is REAL array, dimension ( N ) if
  ICOMPQ = 1, and dimension 1 if ICOMPQ = 0. If ICOMPQ = 1
  and the I-th subproblem is not square, on exit, S( I )
  contains the S-value of a Givens rotation related to
  the right null space of the I-th subproblem.

WORK
  WORK is REAL array, dimension
  (6 * N + (SMLSIZ + 1)*(SMLSIZ + 1)).

IWORK
  IWORK is INTEGER array, dimension (7*N).

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if INFO = 1, a singular value did not converge
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasdq (UPLO, SQRE, N, NCVT, NRU, NCC, D, E, VT, LDVT, U,
           LDU, C, LDC, WORK, INFO)
           SLASDQ computes the SVD of a real bidiagonal matrix with diagonal d
           and off-diagonal e. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasdq (character UPLO, integer SQRE, integer N, integer NCVT,
       integer NRU, integer NCC, real, dimension( * ) D, real, dimension( * )
       E, real, dimension( ldvt, * ) VT, integer LDVT, real, dimension( ldu, *
       ) U, integer LDU, real, dimension( ldc, * ) C, integer LDC, real,
       dimension( * ) WORK, integer INFO)
       SLASDQ computes the SVD of a real bidiagonal matrix with diagonal d and
       off-diagonal e. Used by sbdsdc.

Purpose:
   SLASDQ computes the singular value decomposition (SVD) of a real
   (upper or lower) bidiagonal matrix with diagonal D and offdiagonal
   E, accumulating the transformations if desired. Letting B denote
   the input bidiagonal matrix, the algorithm computes orthogonal
   matrices Q and P such that B = Q * S * P**T (P**T denotes the transpose
   of P). The singular values S are overwritten on D.

   The input matrix U  is changed to U  * Q  if desired.
   The input matrix VT is changed to P**T * VT if desired.
   The input matrix C  is changed to Q**T * C  if desired.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   On entry, UPLO specifies whether the input bidiagonal matrix
   is upper or lower bidiagonal, and wether it is square are not.
   UPLO = 'U' or 'u'   B is upper bidiagonal.
   UPLO = 'L' or 'l'   B is lower bidiagonal.
```

```
SQRE
  SQRE is INTEGER
  = 0: then the input matrix is N-by-N.
  = 1: then the input matrix is N-by-(N+1) if UPLU = 'U' and
  (N+1)-by-N if UPLU = 'L'.

  The bidiagonal matrix has
  N = NL + NR + 1 rows and
  M = N + SQRE >= N columns.

N
  N is INTEGER
  On entry, N specifies the number of rows and columns
  in the matrix. N must be at least 0.

NCVT
  NCVT is INTEGER
  On entry, NCVT specifies the number of columns of
  the matrix VT. NCVT must be at least 0.

NRU
  NRU is INTEGER
  On entry, NRU specifies the number of rows of
  the matrix U. NRU must be at least 0.

NCC
  NCC is INTEGER
  On entry, NCC specifies the number of columns of
  the matrix C. NCC must be at least 0.

D
  D is REAL array, dimension (N)
  On entry, D contains the diagonal entries of the
  bidiagonal matrix whose SVD is desired. On normal exit,
  D contains the singular values in ascending order.

E
  E is REAL array.
  dimension is (N-1) if SQRE = 0 and N if SQRE = 1.
  On entry, the entries of E contain the offdiagonal entries
  of the bidiagonal matrix whose SVD is desired. On normal
  exit, E will contain 0. If the algorithm does not converge,
  D and E will contain the diagonal and superdiagonal entries
  of a bidiagonal matrix orthogonally equivalent to the one given as input.

VT
  VT is REAL array, dimension (LDVT, NCVT)
  On entry, contains a matrix which on exit has been
  premultiplied by P**T, dimension N-by-NCVT if SQRE = 0
  and (N+1)-by-NCVT if SQRE = 1 (not referenced if NCVT=0).
```

```
LDVT
  LDVT is INTEGER
  On entry, LDVT specifies the leading dimension of VT as
  declared in the calling (sub) program. LDVT must be at
  least 1. If NCVT is nonzero LDVT must also be at least N.

U
  U is REAL array, dimension (LDU, N)
  On entry, contains a  matrix which on exit has been
  postmultiplied by Q, dimension NRU-by-N if SQRE = 0
  and NRU-by-(N+1) if SQRE = 1 (not referenced if NRU=0).

LDU
  LDU is INTEGER
  On entry, LDU  specifies the leading dimension of U as
  declared in the calling (sub) program. LDU must be at least max( 1, NRU ) .

C
  C is REAL array, dimension (LDC, NCC)
  On entry, contains an N-by-NCC matrix which on exit
  has been premultiplied by Q**T  dimension N-by-NCC if SQRE = 0
  and (N+1)-by-NCC if SQRE = 1 (not referenced if NCC=0).

LDC
  LDC is INTEGER
  On entry, LDC  specifies the leading dimension of C as
  declared in the calling (sub) program. LDC must be at
  least 1. If NCC is nonzero, LDC must also be at least N.

WORK
  WORK is REAL array, dimension (4*N)
  Workspace. Only referenced if one of NCVT, NRU, or NCC is
  nonzero, and if N is at least 2.

INFO
  INFO is INTEGER
  On exit, a value of 0 indicates a successful exit.
  If INFO < 0, argument number -INFO is illegal.
  If INFO > 0, the algorithm did not converge, and INFO
  specifies how many superdiagonals did not converge.

SYNOPSIS
   Functions/Subroutines
       subroutine slasdt (N, LVL, ND, INODE, NDIML, NDIMR, MSUB)
           SLASDT creates a tree of subproblems for bidiagonal divide and
           conquer. Used by sbdsdc.

Function/Subroutine Documentation
   subroutine slasdt (integer N, integer LVL, integer ND, integer, dimension(
       * ) INODE, integer, dimension( * ) NDIML, integer, dimension( * )
       NDIMR, integer MSUB)
       SLASDT creates a tree of subproblems for bidiagonal divide and conquer.
       Used by sbdsdc.

Purpose:
   SLASDT creates a tree of subproblems for bidiagonal divide and conquer.
```

```
Parameters:

 N
   N is INTEGER
   On entry, the number of diagonal elements of the bidiagonal matrix.

 LVL
   LVL is INTEGER
   On exit, the number of levels on the computation tree.

 ND
   ND is INTEGER
   On exit, the number of nodes on the tree.

 INODE
   INODE is INTEGER array, dimension ( N )
   On exit, centers of subproblems.

 NDIML
   NDIML is INTEGER array, dimension ( N )
   On exit, row dimensions of left children.

 NDIMR
   NDIMR is INTEGER array, dimension ( N )
   On exit, row dimensions of right children.

 MSUB
   MSUB is INTEGER
   On entry, the maximum row dimension each subproblem at the
   bottom of the tree can be of.
```

=====================================================================
Man Page Details
=====================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slaset (UPLO, M, N, ALPHA, BETA, A, LDA)
           SLASET initializes the off-diagonal elements and the diagonal
           elements of a matrix to given values.

Function/Subroutine Documentation
   subroutine slaset (character UPLO, integer M, integer N, real ALPHA, real
       BETA, real, dimension( lda, * ) A, integer LDA)
       SLASET initializes the off-diagonal elements and the diagonal elements
       of a matrix to given values.

Purpose:
   SLASET initializes an m-by-n matrix A to BETA on the diagonal and
   ALPHA on the offdiagonals.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   Specifies the part of the matrix A to be set.
   = 'U':      Upper triangular part is set; the strictly lower
        triangular part of A is not changed.
   = 'L':      Lower triangular part is set; the strictly upper
        triangular part of A is not changed.
   Otherwise:  All of the matrix A is set.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.

 N
   N is INTEGER
   The number of columns of the matrix A.  N >= 0.
```

```
 ALPHA
   ALPHA is REAL
   The constant to which the offdiagonal elements are to be set.

 BETA
   BETA is REAL
   The constant to which the diagonal elements are to be set.

 A
   A is REAL array, dimension (LDA,N)
   On exit, the leading m-by-n submatrix of A is set as follows:

   if UPLO = 'U', A(i,j) = ALPHA, 1<=i<=j-1, 1<=j<=n,
   if UPLO = 'L', A(i,j) = ALPHA, j+1<=i<=m, 1<=j<=n,
   otherwise,     A(i,j) = ALPHA, 1<=i<=m, 1<=j<=n, i.ne.j,

   and, for all UPLO, A(i,i) = BETA, 1<=i<=min(m,n).

 LDA
   LDA is INTEGER
   The leading dimension of the array A.  LDA >= max(1,M).

SYNOPSIS
   Functions/Subroutines
       subroutine slasr (SIDE, PIVOT, DIRECT, M, N, C, S, A, LDA)
           SLASR applies a sequence of plane rotations to a general
           rectangular matrix.
```

```
Function/Subroutine Documentation
   subroutine slasr (character SIDE, character PIVOT, character DIRECT,
       integer M, integer N, real, dimension( * ) C, real, dimension( * ) S,
       real, dimension( lda, * ) A, integer LDA)
       SLASR applies a sequence of plane rotations to a general rectangular
       matrix.

Purpose:
   SLASR applies a sequence of plane rotations to a real matrix A,
   from either the left or the right.

   When SIDE = 'L', the transformation takes the form

   A := P*A

   and when SIDE = 'R', the transformation takes the form

   A := A*P**T

   where P is an orthogonal matrix consisting of a sequence of z plane
   rotations, with z = M when SIDE = 'L' and z = N when SIDE = 'R',
   and P**T is the transpose of P.

   When DIRECT = 'F' (Forward sequence), then

   P = P(z-1) * ... * P(2) * P(1)

   and when DIRECT = 'B' (Backward sequence), then

   P = P(1) * P(2) * ... * P(z-1)

   where P(k) is a plane rotation matrix defined by the 2-by-2 rotation

   R(k) = (  c(k)  s(k) )
        = ( -s(k)  c(k) ).

   When PIVOT = 'V' (Variable pivot), the rotation is performed
   for the plane (k,k+1), i.e., P(k) has the form

       P(k) = (  1                                          )
              (       ...                                   )
              (             1                               )
              (                  c(k)  s(k)                 )
              (                 -s(k)  c(k)                 )
              (                                1             )
              (                                     ...      )
              (                                            1 )

   where R(k) appears as a rank-2 modification to the identity matrix in
```

```
rows and columns k and k+1.

When PIVOT = 'T' (Top pivot), the rotation is performed for the
plane (1,k+1), so P(k) has the form

    P(k) = (  c(k)                    s(k)                 )
           (         1                                     )
           (              ...                              )
           (                    1                          )
           ( -s(k)                   c(k)                  )
           (                                1              )
           (                                     ...       )
           (                                            1 )

where R(k) appears in rows and columns 1 and k+1.

Similarly, when PIVOT = 'B' (Bottom pivot), the rotation is
performed for the plane (k,z), giving P(k) the form

    P(k) = ( 1                                             )
           (      ...                                      )
           (             1                                 )
           (                  c(k)                   s(k) )
           (                        1                     )
           (                             ...              )
           (                                   1          )
           (                 -s(k)                   c(k) )

where R(k) appears in rows and columns k and z.  The rotations are
performed without ever forming P(k) explicitly.

Parameters:

 SIDE
   SIDE is CHARACTER*1
   Specifies whether the plane rotation matrix P is applied to
   A on the left or the right.
   = 'L':  Left, compute A := P*A
   = 'R':  Right, compute A:= A*P**T

 PIVOT
   PIVOT is CHARACTER*1
   Specifies the plane for which P(k) is a plane rotation matrix.
   = 'V':  Variable pivot, the plane (k,k+1)
   = 'T':  Top pivot, the plane (1,k+1)
   = 'B':  Bottom pivot, the plane (k,z)

 DIRECT
   DIRECT is CHARACTER*1
   Specifies whether P is a forward or backward sequence of
```

```
  plane rotations.
  = 'F':  Forward, P = P(z-1)*...*P(2)*P(1)
  = 'B':  Backward, P = P(1)*P(2)*...*P(z-1)

M
  M is INTEGER
  The number of rows of the matrix A.  If m <= 1, an immediate
  return is effected.

N
  N is INTEGER
  The number of columns of the matrix A.  If n <= 1, an
  immediate return is effected.

C
  C is REAL array, dimension (M-1) if SIDE = 'L', (N-1) if SIDE = 'R'
  The cosines c(k) of the plane rotations.

S
  S is REAL array, dimension (M-1) if SIDE = 'L', (N-1) if SIDE = 'R'
  The sines s(k) of the plane rotations.  The 2-by-2 plane
  rotation part of the matrix P(k), R(k), has the form
     R(k) = (  c(k)  s(k) )
            ( -s(k)  c(k) ).

A
  A is REAL array, dimension (LDA,N)
  The M-by-N matrix A.  On exit, A is overwritten by P*A if
  SIDE = 'R' or by A*P**T if SIDE = 'L'.

LDA
  LDA is INTEGER
  The leading dimension of the array A.  LDA >= max(1,M).

Man Page Details
==================================================================

SYNOPSIS
   Functions/Subroutines
       subroutine slassq (N, X, INCX, SCALE, SUMSQ)
           SLASSQ updates a sum of squares represented in scaled form.

Function/Subroutine Documentation
   subroutine slassq (integer N, real, dimension( * ) X, integer INCX, real
       SCALE, real SUMSQ)
       SLASSQ updates a sum of squares represented in scaled form.

Purpose:
   SLASSQ  returns the values  scl  and  smsq  such that

     ( scl**2 )*smsq = x( 1 )**2 +...+ x( n )**2 + ( scale**2 )*sumsq,

   where  x( i ) = X( 1 + ( i - 1 )*INCX ). The value of  sumsq  is
   assumed to be non-negative and  scl  returns the value

     scl = max( scale, abs( x( i ) ) ).

   scale and sumsq must be supplied in SCALE and SUMSQ and
   scl and smsq are overwritten on SCALE and SUMSQ respectively.

   The routine makes only one pass through the vector x.

Parameters:

 N
   N is INTEGER
   The number of elements to be used from the vector X.

 X
   X is REAL array, dimension (N)
   The vector for which a scaled sum of squares is computed.
```

```
  x( i )  = X( 1 + ( i - 1 )*INCX ), 1 <= i <= n.

 INCX
   INCX is INTEGER
   The increment between successive values of the vector X.
   INCX > 0.

 SCALE
   SCALE is REAL
   On entry, the value  scale  in the equation above.
   On exit, SCALE is overwritten with  scl , the scaling factor
   for the sum of squares.

 SUMSQ
   SUMSQ is REAL
   On entry, the value  sumsq  in the equation above.
   On exit, SUMSQ is overwritten with  smsq , the basic sum of
   squares from which  scl  has been factored out.
```

SYNOPSIS
   Functions/Subroutines
       subroutine slasv2 (F, G, H, SSMIN, SSMAX, SNR, CSR, SNL, CSL)
           SLASV2 computes the singular value decomposition of a 2-by-2
           triangular matrix.

Function/Subroutine Documentation
   subroutine slasv2 (real F, real G, real H, real SSMIN, real SSMAX, real
       SNR, real CSR, real SNL, real CSL)
       SLASV2 computes the singular value decomposition of a 2-by-2 triangular
       matrix.

Purpose:
   SLASV2 computes the singular value decomposition of a 2-by-2
   triangular matrix
               [  F   G  ]
```

```
              [  0   H  ].
   On return, abs(SSMAX) is the larger singular value, abs(SSMIN) is the
   smaller singular value, and (CSL,SNL) and (CSR,SNR) are the left and
   right singular vectors for abs(SSMAX), giving the decomposition

              [ CSL  SNL ] [  F   G  ] [ CSR -SNR ]  =  [ SSMAX   0   ]
              [-SNL  CSL ] [  0   H  ] [ SNR  CSR ]     [  0    SSMIN ].

Parameters:

 F
   F is REAL
   The (1,1) element of the 2-by-2 matrix.

 G
   G is REAL
   The (1,2) element of the 2-by-2 matrix.

 H
   H is REAL
   The (2,2) element of the 2-by-2 matrix.

 SSMIN
   SSMIN is REAL
   abs(SSMIN) is the smaller singular value.

 SSMAX
   SSMAX is REAL
   abs(SSMAX) is the larger singular value.

 SNL
   SNL is REAL

 CSL
   CSL is REAL
   The vector (CSL, SNL) is a unit left singular vector for the
   singular value abs(SSMAX).

 SNR
   SNR is REAL

 CSR
   CSR is REAL
   The vector (CSR, SNR) is a unit right singular vector for the
   singular value abs(SSMAX).

Further Details:

   Any input parameter may be aliased with any output parameter.
```

```
Barring over/underflow and assuming a guard digit in subtraction, all
output quantities are correct to within a few units in the last
place (ulps).

In IEEE arithmetic, the code works correctly if one matrix element is
infinite.

Overflow will not occur unless the largest singular value itself
overflows or is within a few ulps of overflow. (On machines with
partial overflow, like the Cray, overflow may occur if the largest
singular value is within a factor of 2 of overflow.)

Underflow is harmless if underflow is gradual. Otherwise, results
may correspond to a matrix modified by perturbations of size near
the underflow threshold.
```
