====================================================================
xerbla_array examples
====================================================================

====================================================================
Man Page Details
====================================================================

subroutine xerbla_array(character(1), dimension(srname_len) SRNAME_ARRAY,
                        integer SRNAME_LEN,
                        integer INFO)
Purpose:
   assists other languages in calling XERBLA, the LAPACK
   and BLAS error handler. Rather than taking a Fortran string argument
   as the function's name, XERBLA_ARRAY takes an array of single
   characters along with the array's length. XERBLA_ARRAY then copies
   up to 32 charaacters of that array into a Fortran string and passes
   that to XERBLA. If called with a non-positive SRNAME_LEN,
   XERBLA_ARRAY will call XERBLA with a string of all blank characters.

   Say some macro or other device makes XERBLA_ARRAY available to C99
   by a name lapack_xerbla and with a common Fortran calling convention.
   Then a C99 program could invoke XERBLA via:
      {
```

```
         int flen = strlen(__func__);
         lapack_xerbla(__func__,&flen,&info);
      }

   Providing XERBLA_ARRAY is not necessary for intercepting LAPACK
   errors. XERBLA_ARRAY calls XERBLA.

Paramenters:

 SRNAME_ARRAY
   CHARACTER(1) array, dimension (SRNAME_LEN)
   The name of the routine which called XERBLA_ARRAY

 SRNAME_LEN
   INTEGER
   The length of the name in SRNAME_ARRY

 INFO
   INTEGER
   The position of the invalid parameter in the parameter list of the
   calling routine.
```

       CBBCSD

Purpose:
   CBBCSD computes the CS decomposition of a unitary matrix in
   bidiagonal-block form,
```

```
          [ B11 | B12 0  0 ]
          [  0  |  0 -I  0 ]
      X = [----------------]
          [ B21 | B22 0  0 ]
          [  0  |  0  0  I ]

                                [  C | -S  0  0 ]
                      [ U1 |    ] [  0 |  0 -I  0 ] [ V1 |    ]**H
                    = [---------] [---------------] [---------]   .
                      [    | U2 ] [  S |  C  0  0 ] [    | V2 ]
                                [  0 |  0  0  I ]
```

X is M-by-M, its top-left block is P-by-Q, and Q must be no larger than P, M-P, or M-Q. (If Q is not the smallest index, then X must be transposed and/or permuted. This can be done in constant time using the TRANS and SIGNS options. See CUNCSD for details.)

The bidiagonal matrices B11, B12, B21, and B22 are represented implicitly by angles THETA(1:Q) and PHI(1:Q-1).

The unitary matrices U1, U2, V1T, and V2T are input/output. The input matrices are pre- or post-multiplied by the appropriate singular vector matrices.

Parameters:

JOBU1
  JOBU1 is CHARACTER
  = 'Y': U1 is updated;
  otherwise: U1 is not updated.

JOBU2
  JOBU2 is CHARACTER
  = 'Y': U2 is updated;
  otherwise: U2 is not updated.

JOBV1T
  JOBV1T is CHARACTER
  = 'Y': V1T is updated;
  otherwise: V1T is not updated.

JOBV2T
  JOBV2T is CHARACTER
  = 'Y': V2T is updated;
  otherwise: V2T is not updated.

TRANS
  TRANS is CHARACTER
  = 'T': X, U1, U2, V1T, and V2T are stored in row-major order;

```
  otherwise:  X, U1, U2, V1T, and V2T are stored in column-major order.

M
  M is INTEGER
  The number of rows and columns in X, the unitary matrix in
  bidiagonal-block form.

P
  P is INTEGER
  The number of rows in the top-left block of X. 0 <= P <= M.

Q
  Q is INTEGER
  The number of columns in the top-left block of X.
  0 <= Q <= MIN(P,M-P,M-Q).

THETA
  THETA is REAL array, dimension (Q)
  On entry, the angles THETA(1),...,THETA(Q) that, along with
  PHI(1), ...,PHI(Q-1), define the matrix in bidiagonal-block
  form. On exit, the angles whose cosines and sines define the
  diagonal blocks in the CS decomposition.

PHI
  PHI is REAL array, dimension (Q-1)
  The angles PHI(1),...,PHI(Q-1) that, along with THETA(1),...,
  THETA(Q), define the matrix in bidiagonal-block form.

U1
  U1 is COMPLEX array, dimension (LDU1,P)
  On entry, an LDU1-by-P matrix. On exit, U1 is postmultiplied
  by the left singular vector matrix common to [ B11 ; 0 ] and
  [ B12 0 0 ; 0 -I 0 0 ].

LDU1
  LDU1 is INTEGER
  The leading dimension of the array U1.

U2
  U2 is COMPLEX array, dimension (LDU2,M-P)
  On entry, an LDU2-by-(M-P) matrix. On exit, U2 is
  postmultiplied by the left singular vector matrix common to
  [ B21 ; 0 ] and [ B22 0 0 ; 0 0 I ].

LDU2
  LDU2 is INTEGER
  The leading dimension of the array U2.

V1T
  V1T is COMPLEX array, dimension (LDV1T,Q)
```

```
  On entry, a LDV1T-by-Q matrix. On exit, V1T is premultiplied
  by the conjugate transpose of the right singular vector
  matrix common to [ B11 ; 0 ] and [ B21 ; 0 ].

LDV1T
  LDV1T is INTEGER
  The leading dimension of the array V1T.

V2T
  V2T is COMPLEX array, dimenison (LDV2T,M-Q)
  On entry, a LDV2T-by-(M-Q) matrix. On exit, V2T is
  premultiplied by the conjugate transpose of the right
  singular vector matrix common to [ B12 0 0 ; 0 -I 0 ] and
  [ B22 0 0 ; 0 0 I ].

LDV2T
  LDV2T is INTEGER
  The leading dimension of the array V2T.

B11D
  B11D is REAL array, dimension (Q)
  When CBBCSD converges, B11D contains the cosines of THETA(1),
  ..., THETA(Q). If CBBCSD fails to converge, then B11D
  contains the diagonal of the partially reduced top-left block.

B11E
  B11E is REAL array, dimension (Q-1)
  When CBBCSD converges, B11E contains zeros. If CBBCSD fails
  to converge, then B11E contains the superdiagonal of the
  partially reduced top-left block.

B12D
  B12D is REAL array, dimension (Q)
  When CBBCSD converges, B12D contains the negative sines of
  THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then
  B12D contains the diagonal of the partially reduced top-right block.

B12E
  B12E is REAL array, dimension (Q-1)
  When CBBCSD converges, B12E contains zeros. If CBBCSD fails
  to converge, then B12E contains the subdiagonal of the
  partially reduced top-right block.

B21D
  B21D is REAL array, dimension (Q)
  When CBBCSD converges, B21D contains the negative sines of
  THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then
  B21D contains the diagonal of the partially reduced bottom-left block.

B21E
```

```
  B21E is REAL array, dimension (Q-1)
  When CBBCSD converges, B21E contains zeros. If CBBCSD fails
  to converge, then B21E contains the subdiagonal of the
  partially reduced bottom-left block.

B22D
  B22D is REAL array, dimension (Q)
  When CBBCSD converges, B22D contains the negative sines of
  THETA(1), ..., THETA(Q). If CBBCSD fails to converge, then
  B22D contains the diagonal of the partially reduced bottom-right block.

B22E
  B22E is REAL array, dimension (Q-1)
  When CBBCSD converges, B22E contains zeros. If CBBCSD fails
  to converge, then B22E contains the subdiagonal of the
  partially reduced bottom-right block.

RWORK
  RWORK is REAL array, dimension (MAX(1,LWORK))
  On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LRWORK
  LRWORK is INTEGER
  The dimension of the array RWORK. LRWORK >= MAX(1,8*Q).

  If LRWORK = -1, then a workspace query is assumed; the
  routine only calculates the optimal size of the RWORK array,
  returns this value as the first entry of the work array, and
  no error message related to LRWORK is issued by XERBLA.

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
  > 0:  if CBBCSD did not converge, INFO specifies the number
  of nonzero entries in PHI, and B11D, B11E, etc.,
  contain the partially reduced matrix.

Internal Parameters:

TOLMUL  REAL, default = MAX(10,MIN(100,EPS**(-1/8)))
  TOLMUL controls the convergence criterion of the QR loop.
  Angles THETA(i), PHI(i) are rounded to 0 or PI/2 when they
  are within TOLMUL*EPS of either bound.

SYNOPSIS
   Functions/Subroutines
       subroutine cbdsqr (UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU, C,
           LDC, RWORK, INFO)
           CBDSQR

Function/Subroutine Documentation
   subroutine cbdsqr (character UPLO, integer N, integer NCVT, integer NRU,
       integer NCC, real, dimension( * ) D, real, dimension( * ) E, complex,
       dimension( ldvt, * ) VT, integer LDVT, complex, dimension( ldu, * ) U,
       integer LDU, complex, dimension( ldc, * ) C, integer LDC, real,
       dimension( * ) RWORK, integer INFO)
       CBDSQR
```

```
Purpose:
   CBDSQR computes the singular values and, optionally, the right and/or
   left singular vectors from the singular value decomposition (SVD) of
   a real N-by-N (upper or lower) bidiagonal matrix B using the implicit
   zero-shift QR algorithm.  The SVD of B has the form

   B = Q * S * P**H

   where S is the diagonal matrix of singular values, Q is an orthogonal
   matrix of left singular vectors, and P is an orthogonal matrix of
   right singular vectors.  If left singular vectors are requested, this
   subroutine actually returns U*Q instead of Q, and, if right singular
   vectors are requested, this subroutine returns P**H*VT instead of
   P**H, for given complex input matrices U and VT.  When U and VT are
   the unitary matrices that reduce a general matrix A to bidiagonal
   form: A = U*B*VT, as computed by CGEBRD, then

   A = (U*Q) * S * (P**H*VT)

   is the SVD of A.  Optionally, the subroutine may also compute Q**H*C
   for a given complex input matrix C.

Parameters:

 UPLO
   UPLO is CHARACTER*1
   = 'U':  B is upper bidiagonal;
   = 'L':  B is lower bidiagonal.

 N
   N is INTEGER
   The order of the matrix B.  N >= 0.

 NCVT
   NCVT is INTEGER
   The number of columns of the matrix VT. NCVT >= 0.

 NRU
   NRU is INTEGER
   The number of rows of the matrix U. NRU >= 0.

 NCC
   NCC is INTEGER
   The number of columns of the matrix C. NCC >= 0.

 D
   D is REAL array, dimension (N)
   On entry, the n diagonal elements of the bidiagonal matrix B.
   On exit, if INFO=0, the singular values of B in decreasing order.
```

```
E
  E is REAL array, dimension (N-1)
  On entry, the N-1 offdiagonal elements of the bidiagonal
  matrix B.
  On exit, if INFO = 0, E is destroyed; if INFO > 0, D and E
  will contain the diagonal and superdiagonal elements of a
  bidiagonal matrix orthogonally equivalent to the one given as input.

  VT
  VT is COMPLEX array, dimension (LDVT, NCVT)
  On entry, an N-by-NCVT matrix VT.
  On exit, VT is overwritten by P**H * VT.
  Not referenced if NCVT = 0.

LDVT
  LDVT is INTEGER
  The leading dimension of the array VT.
  LDVT >= max(1,N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U
  U is COMPLEX array, dimension (LDU, N)
  On entry, an NRU-by-N matrix U.
  On exit, U is overwritten by U * Q.
  Not referenced if NRU = 0.

LDU
  LDU is INTEGER
  The leading dimension of the array U.  LDU >= max(1,NRU).

C
  C is COMPLEX array, dimension (LDC, NCC)
  On entry, an N-by-NCC matrix C.
  On exit, C is overwritten by Q**H * C.
  Not referenced if NCC = 0.

LDC
  LDC is INTEGER
  The leading dimension of the array C.
  LDC >= max(1,N) if NCC > 0; LDC >=1 if NCC = 0.

RWORK
  RWORK is REAL array, dimension (4*N)

INFO
  INFO is INTEGER
  = 0:  successful exit
  < 0:  If INFO = -i, the i-th argument had an illegal value
  > 0:  the algorithm did not converge; D and E contain the
  elements of a bidiagonal matrix which is orthogonally
```

```
   similar to the input matrix B;  if INFO = i, i
   elements of E have not converged to zero.

Internal Parameters:

 TOLMUL  REAL, default = max(10,min(100,EPS**(-1/8)))
   TOLMUL controls the convergence criterion of the QR loop.

   If it is positive, TOLMUL*EPS is the desired relative
   precision in the computed singular values.

   If it is negative, abs(TOLMUL*EPS*sigma_max) is the
   desired absolute accuracy in the computed singular
   values (corresponds to relative accuracy
   abs(TOLMUL*EPS) in the largest singular value.

   abs(TOLMUL) should be between 1 and 1/EPS, and preferably
   between 10 (for fast convergence) and .1/EPS
   (for there to be some accuracy in the results).

   Default is to lose at either one eighth or 2 of the
   available decimal digits in each computed singular value
   (whichever is smaller).

 MAXITR  INTEGER, default = 6
   MAXITR controls the maximum number of passes of the
   algorithm through its inner loop. The algorithms stops
   (and so fails to converge) if the number of passes
   through the inner loop exceeds MAXITR*N**2.
```

SYNOPSIS
   Functions/Subroutines
       subroutine cgbbrd (VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ, PT,
           LDPT, C, LDC, WORK, RWORK, INFO)
           CGBBRD

Function/Subroutine Documentation
   subroutine cgbbrd (character VECT, integer M, integer N, integer NCC,
       integer KL, integer KU, complex, dimension( ldab, * ) AB, integer LDAB,
       real, dimension( * ) D, real, dimension( * ) E, complex, dimension(
       ldq, * ) Q, integer LDQ, complex, dimension( ldpt, * ) PT, integer
       LDPT, complex, dimension( ldc, * ) C, integer LDC, complex, dimension(
       * ) WORK, real, dimension( * ) RWORK, integer INFO)
       CGBBRD

Purpose:
   CGBBRD reduces a complex general m-by-n band matrix A to real upper
   bidiagonal form B by a unitary transformation: Q**H * A * P = B.

   The routine computes B, and optionally forms Q or P**H, or computes
   Q**H*C for a given matrix C.

Parameters:

 VECT
   VECT is CHARACTER*1
   Specifies whether or not the matrices Q and P**H are to be
   formed.
   = 'N': do not form Q or P**H;
   = 'Q': form Q only;
   = 'P': form P**H only;
   = 'B': form both.

 M
   M is INTEGER
   The number of rows of the matrix A.  M >= 0.
```

```
N
  N is INTEGER
  The number of columns of the matrix A.  N >= 0.

NCC
  NCC is INTEGER
  The number of columns of the matrix C.  NCC >= 0.

KL
  KL is INTEGER
  The number of subdiagonals of the matrix A. KL >= 0.

KU
  KU is INTEGER
  The number of superdiagonals of the matrix A. KU >= 0.

AB
  AB is COMPLEX array, dimension (LDAB,N)
  On entry, the m-by-n band matrix A, stored in rows 1 to
  KL+KU+1. The j-th column of A is stored in the j-th column of
  the array AB as follows:
  AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).
  On exit, A is overwritten by values generated during the
  reduction.

LDAB
  LDAB is INTEGER
  The leading dimension of the array A. LDAB >= KL+KU+1.

D
  D is REAL array, dimension (min(M,N))
  The diagonal elements of the bidiagonal matrix B.

E
  E is REAL array, dimension (min(M,N)-1)
  The superdiagonal elements of the bidiagonal matrix B.

Q
  Q is COMPLEX array, dimension (LDQ,M)
  If VECT = 'Q' or 'B', the m-by-m unitary matrix Q.
  If VECT = 'N' or 'P', the array Q is not referenced.

LDQ
  LDQ is INTEGER
  The leading dimension of the array Q.
  LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT
  PT is COMPLEX array, dimension (LDPT,N)
  If VECT = 'P' or 'B', the n-by-n unitary matrix P'.
```

```
  If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT
  LDPT is INTEGER
  The leading dimension of the array PT.
  LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C
  C is COMPLEX array, dimension (LDC,NCC)
  On entry, an m-by-ncc matrix C.
  On exit, C is overwritten by Q**H*C.
  C is not referenced if NCC = 0.

LDC
  LDC is INTEGER
  The leading dimension of the array C.
  LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK
  WORK is COMPLEX array, dimension (max(M,N))

RWORK
  RWORK is REAL array, dimension (max(M,N))

INFO
  INFO is INTEGER
  = 0:  successful exit.
  < 0:  if INFO = -i, the i-th argument had an illegal value.
```

NAME
       DBDSDC - the singular value decomposition (SVD) of a real N-by-N (upper
       or lower) bidiagonal matrix B

SYNOPSIS
       SUBROUTINE DBDSDC( UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ, WORK,
                          IWORK, INFO )

           CHARACTER      COMPQ, UPLO

           INTEGER        INFO, LDU, LDVT, N

           INTEGER        IQ( * ), IWORK( * )

           DOUBLE         PRECISION  D(  * ), E( * ), Q( * ), U( LDU, * ), VT(
                          LDVT, * ), WORK( * )
```

PURPOSE

DBDSDC computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = U * S * VT, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. DBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See DLASD3 for details.

The code currently calls DLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

UPLO (input) CHARACTER*1
= 'U': B is upper bidiagonal.
= 'L': B is lower bidiagonal.

COMPQ (input) CHARACTER*1
Specifies whether singular vectors are to be computed as follows:
= 'N': Compute singular values only;
= 'P': Compute singular values and compute singular vectors in compact form; = 'I': Compute singular values and singular vectors.

N (input) INTEGER
The order of the matrix B. N >= 0.

D (input/output) DOUBLE PRECISION array, dimension (N)
On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E (input/output) DOUBLE PRECISION array, dimension (N-1)
On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U (output) DOUBLE PRECISION array, dimension (LDU,N)
If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other val-

```
          ues of COMPQ, U is not referenced.

     LDU  (input) INTEGER
          The  leading  dimension of the array U.  LDU >= 1.  If singular
          vectors are desired, then LDU >= max( 1, N ).

     VT   (output) DOUBLE PRECISION array, dimension (LDVT,N)
          If  COMPQ = 'I', then: On exit, if INFO = 0, VT'  contains  the
          right  singular  vectors  of  the bidiagonal matrix.  For other
          values of COMPQ, VT is not referenced.

     LDVT (input) INTEGER
          The leading dimension of the array VT.  LDVT >= 1.  If singular
          vectors are desired, then LDVT >= max( 1, N ).

     Q    (output) DOUBLE PRECISION array, dimension (LDQ)
          If   COMPQ  = 'P', then: On exit, if INFO = 0, Q and IQ contain
          the left and right singular vectors in a compact form,  requir-
          ing  O(N log N) space instead of 2*N**2.  In particular, Q con-
          tains all the DOUBLE PRECISION data in LDQ >= N*(11 +  2*SMLSIZ
          +  8*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is
          returned by ILAENV and is equal to the maximum size of the sub-
          problems  at  the bottom of the computation tree (usually about
          25).  For other values of COMPQ, Q is not referenced.

     IQ   (output) INTEGER array, dimension (LDIQ)
          If  COMPQ = 'P', then: On exit, if INFO = 0, Q and  IQ  contain
          the  left and right singular vectors in a compact form, requir-
          ing O(N log N) space instead of 2*N**2.  In particular, IQ con-
          tains  all  INTEGER  data in LDIQ >= N*(3 + 3*INT(LOG_2(N/(SML-
          SIZ+1)))) words of memory, where SMLSIZ is returned  by  ILAENV
          and is equal to the maximum size of the subproblems at the bot-
          tom of the computation tree (usually about 25).  For other val-
          ues of COMPQ, IQ is not referenced.

     WORK (workspace) DOUBLE PRECISION array, dimension (MAX(1,LWORK))
          If  COMPQ  =  'N'  then  LWORK >= (4 * N).  If COMPQ = 'P' then
          LWORK >= (6 * N).  If COMPQ = 'I' then LWORK >= (3 * N**2 + 4 *
          N).

     IWORK (workspace) INTEGER array, dimension (8*N)

     INFO (output) INTEGER
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an illegal value.
          >  0:   The algorithm failed to compute an singular value.  The
          update process of divide and conquer failed.

Further Details

   California at Berkeley, USA
```

The input arguments are:

- uplo - simple-array character (1)
- compq - (simple-array character (1)
- n - fixnum
- d - array doublefloat
- e - array doublefloat
- u - array doublefloat
- ldu - fixnum
- vt - doublefloat
- ldvt - fixnum
- q - array doublefloat
- iq - array fixnum
- work - array doublefloat
- iwork - array fixnum
- info - fixnum

The return values are:

- uplo - nil
- compq - nil
- n - nil
- d - nil
- e - nil
- u - nil
- ldu - nil

- vt - nil
- ldvt - nil
- q - nil
- iq - nil
- work - nil
- iwork - nil
- info - info

NAME
       DBDSQR  -  the  singular  values and, optionally, the right and/or left
       singular vectors from the singular value decomposition (SVD) of a  real
       N-by-N  (upper  or  lower) bidiagonal matrix B using the implicit zero-
       shift QR algorithm

SYNOPSIS
       SUBROUTINE DBDSQR( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU,  C,
                          LDC, WORK, INFO )

           CHARACTER      UPLO

           INTEGER        INFO, LDC, LDU, LDVT, N, NCC, NCVT, NRU

           DOUBLE         PRECISION  C( LDC, * ), D( * ), E( * ), U( LDU, * ),
                          VT( LDVT, * ), WORK( * )

PURPOSE
       DBDSQR computes the singular values and, optionally, the  right  and/or
       left  singular vectors from the singular value decomposition (SVD) of a
       real N-by-N (upper or lower) bidiagonal matrix  B  using  the  implicit
       zero-shift QR algorithm.  The SVD of B has the form

          B = Q * S * P**T

       where  S  is the diagonal matrix of singular values, Q is an orthogonal
       matrix of left singular vectors, and P is an orthogonal matrix of right
       singular vectors.  If left singular vectors are requested, this subrou-
       tine actually returns U*Q instead of Q, and, if right singular  vectors
       are  requested,  this  subroutine  returns P**T*VT instead of P**T, for
       given real input matrices U and VT.  When U and VT are  the  orthogonal
       matrices  that  reduce  a  general  matrix  A  to bidiagonal form:  A =
       U*B*VT, as computed by DGEBRD, then

          A = (U*Q) * S * (P**T*VT)

       is the SVD of A.  Optionally, the subroutine may  also  compute  Q**T*C
       for a given real input matrix C.

       See "Computing  Small Singular Values of Bidiagonal Matrices With Guar-
```

```
anteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Work-
ing Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp.
873-912, Sept 1990) and
"Accurate singular values and differential qd algorithms," by B. Par-
lett and V. Fernando, Technical Report CPAM-554, Mathematics Depart-
ment, University of California at Berkeley, July 1992 for a detailed
description of the algorithm.

ARGUMENTS
      UPLO    (input) CHARACTER*1
              = 'U':  B is upper bidiagonal;
              = 'L':  B is lower bidiagonal.

      N       (input) INTEGER
              The order of the matrix B.  N >= 0.

      NCVT    (input) INTEGER
              The number of columns of the matrix VT. NCVT >= 0.

      NRU     (input) INTEGER
              The number of rows of the matrix U. NRU >= 0.

      NCC     (input) INTEGER
              The number of columns of the matrix C. NCC >= 0.

      D       (input/output) DOUBLE PRECISION array, dimension (N)
              On entry, the n diagonal elements of the bidiagonal matrix B.
              On exit, if INFO=0, the singular values of B in decreasing
              order.

      E       (input/output) DOUBLE PRECISION array, dimension (N-1)
              On entry, the N-1 offdiagonal elements of the bidiagonal matrix
              B.  On exit, if INFO = 0, E is destroyed; if INFO > 0, D and E
              will contain the diagonal and superdiagonal elements of a bidi-
              agonal matrix orthogonally equivalent to the one given as
              input.

      VT      (input/output) DOUBLE PRECISION array, dimension (LDVT, NCVT)
              On entry, an N-by-NCVT matrix VT.  On exit, VT is overwritten
              by P**T * VT.  Not referenced if NCVT = 0.

      LDVT    (input) INTEGER
              The leading dimension of the array VT.  LDVT >= max(1,N) if
              NCVT > 0; LDVT >= 1 if NCVT = 0.

      U       (input/output) DOUBLE PRECISION array, dimension (LDU, N)
              On entry, an NRU-by-N matrix U.  On exit, U is overwritten by U
              * Q.  Not referenced if NRU = 0.
```

```
      LDU     (input) INTEGER
              The leading dimension of the array U.  LDU >= max(1,NRU).

      C       (input/output) DOUBLE PRECISION array, dimension (LDC, NCC)
              On entry, an N-by-NCC matrix C.  On exit, C is  overwritten  by
              Q**T * C.  Not referenced if NCC = 0.

      LDC     (input) INTEGER
              The leading dimension of the array C.  LDC >= max(1,N) if NCC >
              0; LDC >=1 if NCC = 0.

      WORK    (workspace) DOUBLE PRECISION array, dimension (2*N)
              if NCVT = NRU = NCC = 0, (max(1, 4*N)) otherwise

      INFO    (output) INTEGER
              = 0:  successful exit
              < 0:  If INFO = -i, the i-th argument had an illegal value
              > 0:  the algorithm did not converge; D and E contain the  ele-
              ments  of  a bidiagonal matrix which is orthogonally similar to
              the input matrix B;  if INFO = i, i elements of E have not con-
              verged to zero.

PARAMETERS
      TOLMUL  DOUBLE PRECISION, default = max(10,min(100,EPS**(-1/8)))
              TOLMUL  controls  the convergence criterion of the QR loop.  If
              it is positive, TOLMUL*EPS is the desired relative precision in
              the  computed  singular  values.   If  it is negative, abs(TOL-
              MUL*EPS*sigma_max) is the desired absolute accuracy in the com-
              puted  singular  values  (corresponds  to  relative  accuracy
              abs(TOLMUL*EPS) in the  largest  singular  value.   abs(TOLMUL)
              should  be  between 1 and 1/EPS, and preferably between 10 (for
              fast convergence) and .1/EPS (for there to be some accuracy  in
              the  results).  Default is to lose at either one eighth or 2 of
              the available decimal digits in each  computed  singular  value
              (whichever is smaller).

      MAXITR  INTEGER, default = 6
              MAXITR  controls  the maximum number of passes of the algorithm
              through its inner loop. The algorithms stops (and so  fails  to
              converge)  if  the  number  of  passes  through  the inner loop
              exceeds MAXITR*N**2.

NAME
       DDISNA  -  the  reciprocal  condition numbers for the eigenvectors of a
       real symmetric or complex Hermitian matrix or for  the  left  or  right
       singular vectors of a general m-by-n matrix

SYNOPSIS
       SUBROUTINE DDISNA( JOB, M, N, D, SEP, INFO )

           CHARACTER      JOB

           INTEGER        INFO, M, N

           DOUBLE         PRECISION D( * ), SEP( * )

PURPOSE
       DDISNA  computes  the reciprocal condition numbers for the eigenvectors
       of a real symmetric or complex Hermitian matrix  or  for  the  left  or
       right  singular vectors of a general m-by-n matrix. The reciprocal con-
       dition number is the 'gap' between the corresponding eigenvalue or sin-
       gular value and the nearest other one.

       The  bound on the error, measured by angle in radians, in the I-th com-
       puted vector is given by

              DLAMCH( 'E' ) * ( ANORM / SEP( I ) )

       where ANORM = 2-norm(A) = max( abs( D(j) ) ).  SEP(I) is not allowed to
       be  smaller  than DLAMCH( 'E' )*ANORM in order to limit the size of the
       error bound.

       DDISNA may also be used to compute error bounds for eigenvectors of the
       generalized symmetric definite eigenproblem.

ARGUMENTS
       JOB     (input) CHARACTER*1
               Specifies  for  which  problem the reciprocal condition numbers
               should be computed:
               = 'E':  the eigenvectors of a symmetric/Hermitian matrix;
               = 'L':  the left singular vectors of a general matrix;
               = 'R':  the right singular vectors of a general matrix.

       M       (input) INTEGER
               The number of rows of the matrix. M >= 0.
```

```
N       (input) INTEGER
        If JOB = 'L' or 'R', the number of columns of  the  matrix,  in
        which case N >= 0. Ignored if JOB = 'E'.

D       (input) DOUBLE PRECISION array, dimension (M) if JOB = 'E'
        dimension  (min(M,N))  if  JOB = 'L' or 'R' The eigenvalues (if
        JOB = 'E') or singular values (if JOB =  'L'  or  'R')  of  the
        matrix,  in  either increasing or decreasing order. If singular
        values, they must be non-negative.

SEP     (output) DOUBLE PRECISION array, dimension (M) if JOB = 'E'
        dimension (min(M,N)) if JOB = 'L' or 'R' The reciprocal  condi-
        tion numbers of the vectors.

INFO    (output) INTEGER
        = 0:  successful exit.
        < 0:  if INFO = -i, the i-th argument had an illegal value.
```

NAME
       DGEBAK  -  the  right  or left eigenvectors of a real general matrix by
       backward transformation on the computed eigenvectors  of  the  balanced
       matrix output by DGEBAL

SYNOPSIS
       SUBROUTINE DGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO )

           CHARACTER      JOB, SIDE

           INTEGER        IHI, ILO, INFO, LDV, M, N

           DOUBLE         PRECISION SCALE( * ), V( LDV, * )

PURPOSE
       DGEBAK forms the right or left eigenvectors of a real general matrix by
```

```
      backward transformation on the computed eigenvectors  of  the  balanced
      matrix output by DGEBAL.

ARGUMENTS
      JOB     (input) CHARACTER*1
              Specifies  the type of backward transformation required: = 'N',
              do nothing, return immediately; = 'P', do backward  transforma-
              tion  for  permutation  only; = 'S', do backward transformation
              for scaling only; = 'B', do backward transformations  for  both
              permutation  and scaling.  JOB must be the same as the argument
              JOB supplied to DGEBAL.

      SIDE    (input) CHARACTER*1
              = 'R':  V contains right eigenvectors;
              = 'L':  V contains left eigenvectors.

      N       (input) INTEGER
              The number of rows of the matrix V.  N >= 0.

      ILO     (input) INTEGER
              IHI     (input) INTEGER The integers ILO and IHI determined  by
              DGEBAL.   1  <=  ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if
              N=0.

      SCALE   (input) DOUBLE PRECISION array, dimension (N)
              Details of the permutation and scaling factors, as returned  by
              DGEBAL.

      M       (input) INTEGER
              The number of columns of the matrix V.  M >= 0.

      V       (input/output) DOUBLE PRECISION array, dimension (LDV,M)
              On entry, the matrix of right or left eigenvectors to be trans-
              formed, as returned by DHSEIN or DTREVC.  On exit, V  is  over-
              written by the transformed eigenvectors.

      LDV     (input) INTEGER
              The leading dimension of the array V. LDV >= max(1,N).

      INFO    (output) INTEGER
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an illegal value.

NAME
       DGEBAL - a general real matrix A

SYNOPSIS
       SUBROUTINE DGEBAL( JOB, N, A, LDA, ILO, IHI, SCALE, INFO )

           CHARACTER      JOB

           INTEGER        IHI, ILO, INFO, LDA, N
```

```
      DOUBLE         PRECISION A( LDA, * ), SCALE( * )
```

PURPOSE

DGEBAL balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input) CHARACTER*1
Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) INTEGER
The order of the matrix A. N >= 0.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details. LDA (input) INTEGER The leading dimension of the array A. LDA >= max(1,N).

ILO (output) INTEGER
IHI (output) INTEGER ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE (output) DOUBLE PRECISION array, dimension (N)
Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO (output) INTEGER
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

```
FURTHER DETAILS
       The  permutations  consist of row and column interchanges which put the
       matrix in the form

                 ( T1   X   Y  )
          P A P = (  0   B   Z  )
                 (  0   0   T2 )

       where T1 and T2 are upper triangular  matrices  whose  eigenvalues  lie
       along  the  diagonal.  The column indices ILO and IHI mark the starting
       and ending columns of the submatrix B. Balancing consists of applying a
       diagonal  similarity  transformation inv(D) * B * D to make the 1-norms
       of each row of B and its corresponding column nearly equal.  The output
       matrix is

          ( T1     X*D          Y    )
          (  0  inv(D)*B*D  inv(D)*Z ).
          (  0      0           T2   )

       Information  about  the  permutations  P  and  the diagonal matrix D is
       returned in the vector SCALE.

       This subroutine is based on the EISPACK routine BALANC.

NAME
       DGEBD2  -  a  real general m by n matrix A to upper or lower bidiagonal
       form B by an orthogonal transformation

SYNOPSIS
       SUBROUTINE DGEBD2( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, INFO )

           INTEGER        INFO, LDA, M, N

           DOUBLE         PRECISION A( LDA, * ), D( * ), E( * ),  TAUP(  *  ),
                          TAUQ( * ), WORK( * )

PURPOSE
       DGEBD2 reduces a real general m by n matrix A to upper or lower bidiag-
       onal form B by an orthogonal transformation: Q' * A * P = B.

       If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS
       M       (input) INTEGER
               The number of rows in the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns in the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the m by n general matrix to be reduced.  On exit, if
               m  >= n, the diagonal and the first superdiagonal are overwrit-
               ten with the upper bidiagonal matrix B; the elements below  the
               diagonal,  with the array TAUQ, represent the orthogonal matrix
               Q as a product of elementary reflectors, and the elements above
               the  first  superdiagonal,  with  the array TAUP, represent the
               orthogonal matrix P as a product of elementary reflectors; if m
               <  n,  the  diagonal  and the first subdiagonal are overwritten
               with the lower bidiagonal matrix  B;  the  elements  below  the
               first  subdiagonal, with the array TAUQ, represent the orthogo-
               nal matrix Q as a product of  elementary  reflectors,  and  the
               elements above the diagonal, with the array TAUP, represent the
               orthogonal matrix P as a product of elementary reflectors.  See
               Further Details.  LDA     (input) INTEGER The leading dimension
               of the array A.  LDA >= max(1,M).

       D       (output) DOUBLE PRECISION array, dimension (min(M,N))
               The diagonal elements  of  the  bidiagonal  matrix  B:  D(i)  =
               A(i,i).
```

```
E       (output) DOUBLE PRECISION array, dimension (min(M,N)-1)
        The  off-diagonal  elements of the bidiagonal matrix B: if m >=
        n, E(i) = A(i,i+1) for i =  1,2,...,n-1;  if  m  <  n,  E(i)  =
        A(i+1,i) for i = 1,2,...,m-1.

TAUQ    (output) DOUBLE PRECISION array dimension (min(M,N))
        The scalar factors of the elementary reflectors which represent
        the orthogonal matrix Q. See Further Details.  TAUP    (output)
        DOUBLE PRECISION array, dimension (min(M,N)) The scalar factors
        of the elementary reflectors  which  represent  the  orthogonal
        matrix P. See Further Details.  WORK    (workspace) DOUBLE PRE-
        CISION array, dimension (max(M,N))

INFO    (output) INTEGER
        = 0: successful exit.
        < 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
       The matrices Q and P are represented as products of elementary  reflec-
       tors:

       If m >= n,

          Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

       Each H(i) and G(i) has the form:

          H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

       where  tauq  and  taup  are real scalars, and v and u are real vectors;
       v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit  in  A(i+1:m,i);
       u(1:i)  =  0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n);
       tauq is stored in TAUQ(i) and taup in TAUP(i).

       If m < n,

          Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

       Each H(i) and G(i) has the form:

          H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

       where tauq and taup are real scalars, and v and  u  are  real  vectors;
       v(1:i)  =  0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i);
       u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit  in  A(i,i+1:n);
       tauq is stored in TAUQ(i) and taup in TAUP(i).

       The contents of A on exit are illustrated by the following examples:

       m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):
```

```
( d   e   u1  u1  u1 )          ( d   u1  u1  u1  u1  u1 )
( v1  d   e   u2  u2 )          ( e   d   u2  u2  u2  u2 )
( v1  v2  d   e   u3 )          ( v1  e   d   u3  u3  u3 )
( v1  v2  v3  d   e  )          ( v1  v2  e   d   u4  u4 )
( v1  v2  v3  v4  d  )          ( v1  v2  v3  e   d   u5 )
( v1  v2  v3  v4  v5 )
```

where d and e denote diagonal and off-diagonal elements of B, vi denotes an element of the vector defining H(i), and ui an element of the vector defining G(i).

NAME
       DGEBRD  -  a  general real M-by-N matrix A to upper or lower bidiagonal
       form B by an orthogonal transformation

SYNOPSIS
       SUBROUTINE DGEBRD( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO )

           INTEGER        INFO, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), D( * ), E( * ),  TAUP(  *  ),
                          TAUQ( * ), WORK( * )

PURPOSE
       DGEBRD reduces a general real M-by-N matrix A to upper or lower bidiag-
       onal form B by an orthogonal transformation: Q**T * A * P = B.

       If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS
       M       (input) INTEGER
               The number of rows in the matrix A.  M >= 0.

       N       (input) INTEGER
```

```
        The number of columns in the matrix A.  N >= 0.

A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
        On entry, the M-by-N general matrix to be reduced.  On exit, if
        m  >= n, the diagonal and the first superdiagonal are overwrit-
        ten with the upper bidiagonal matrix B; the elements below  the
        diagonal,  with the array TAUQ, represent the orthogonal matrix
        Q as a product of elementary reflectors, and the elements above
        the  first  superdiagonal,  with  the array TAUP, represent the
        orthogonal matrix P as a product of elementary reflectors; if m
        <  n,  the  diagonal  and the first subdiagonal are overwritten
        with the lower bidiagonal matrix  B;  the  elements  below  the
        first  subdiagonal, with the array TAUQ, represent the orthogo-
        nal matrix Q as a product of  elementary  reflectors,  and  the
        elements above the diagonal, with the array TAUP, represent the
        orthogonal matrix P as a product of elementary reflectors.  See
        Further Details.  LDA     (input) INTEGER The leading dimension
        of the array A.  LDA >= max(1,M).

D       (output) DOUBLE PRECISION array, dimension (min(M,N))
        The diagonal elements  of  the  bidiagonal  matrix  B:  D(i)  =
        A(i,i).

E       (output) DOUBLE PRECISION array, dimension (min(M,N)-1)
        The  off-diagonal  elements of the bidiagonal matrix B: if m >=
        n, E(i) = A(i,i+1) for i =  1,2,...,n-1;  if  m  <  n,  E(i)  =
        A(i+1,i) for i = 1,2,...,m-1.

TAUQ    (output) DOUBLE PRECISION array dimension (min(M,N))
        The scalar factors of the elementary reflectors which represent
        the orthogonal matrix Q. See Further Details.  TAUP    (output)
        DOUBLE PRECISION array, dimension (min(M,N)) The scalar factors
        of the elementary reflectors  which  represent  the  orthogonal
        matrix P. See Further Details.  WORK    (workspace/output) DOU-
        BLE PRECISION array, dimension (MAX(1,LWORK)) On exit, if  INFO
        = 0, WORK(1) returns the optimal LWORK.

LWORK   (input) INTEGER
        The  length of the array WORK.  LWORK >= max(1,M,N).  For opti-
        mum performance LWORK >= (M+N)*NB,  where  NB  is  the  optimal
        blocksize.

        If  LWORK  = -1, then a workspace query is assumed; the routine
        only calculates the optimal size of  the  WORK  array,  returns
        this  value  as the first entry of the WORK array, and no error
        message related to LWORK is issued by XERBLA.

INFO    (output) INTEGER
        = 0:  successful exit
        < 0:  if INFO = -i, the i-th argument had an illegal value.
```

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If m >= n,

```
Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)
```

Each H(i) and G(i) has the form:

```
H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'
```

where tauq and taup are real scalars, and v and u are real vectors; v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

If m < n,

```
Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)
```

Each H(i) and G(i) has the form:

```
H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'
```

where tauq and taup are real scalars, and v and u are real vectors; v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i); u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

m = 6 and n = 5 (m > n):

```
( d   e   u1  u1  u1 )
( v1  d   e   u2  u2 )
( v1  v2  d   e   u3 )
( v1  v2  v3  d   e  )
( v1  v2  v3  v4  d  )
( v1  v2  v3  v4  v5 )
```

m = 5 and n = 6 (m < n):

```
( d   u1  u1  u1  u1  u1 )
( e   d   u2  u2  u2  u2 )
( v1  e   d   u3  u3  u3 )
( v1  v2  e   d   u4  u4 )
( v1  v2  v3  e   d   u5 )
```

where d and e denote diagonal and off-diagonal elements of B, vi denotes an element of the vector defining H(i), and ui an element of the vector defining G(i).

NAME
       DGEEV  - for an N-by-N real nonsymmetric matrix A, the eigenvalues and,
       optionally, the left and/or right eigenvectors

SYNOPSIS
       SUBROUTINE DGEEV( JOBVL, JOBVR, N, A, LDA, WR, WI, VL, LDVL, VR,  LDVR,
                         WORK, LWORK, INFO )

           CHARACTER     JOBVL, JOBVR

           INTEGER       INFO, LDA, LDVL, LDVR, LWORK, N

           DOUBLE        PRECISION  A( LDA, * ), VL( LDVL, * ), VR( LDVR, * ),
                         WI( * ), WORK( * ), WR( * )

PURPOSE
       DGEEV computes for an N-by-N real nonsymmetric matrix A, the  eigenval-
       ues and, optionally, the left and/or right eigenvectors.

       The right eigenvector v(j) of A satisfies
                        A * v(j) = lambda(j) * v(j)
       where lambda(j) is its eigenvalue.
       The left eigenvector u(j) of A satisfies
                     u(j)**H * A = lambda(j) * u(j)**H
```

```
      where u(j)**H denotes the conjugate transpose of u(j).

      The  computed  eigenvectors are normalized to have Euclidean norm equal
      to 1 and largest component real.

ARGUMENTS
      JOBVL   (input) CHARACTER*1
              = 'N': left eigenvectors of A are not computed;
              = 'V': left eigenvectors of A are computed.

      JOBVR   (input) CHARACTER*1
              = 'N': right eigenvectors of A are not computed;
              = 'V': right eigenvectors of A are computed.

      N       (input) INTEGER
              The order of the matrix A. N >= 0.

      A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
              On entry, the N-by-N matrix A.  On exit, A has  been  overwrit-
              ten.

      LDA     (input) INTEGER
              The leading dimension of the array A.  LDA >= max(1,N).

      WR      (output) DOUBLE PRECISION array, dimension (N)
              WI       (output)  DOUBLE PRECISION array, dimension (N) WR and
              WI contain the real and imaginary parts, respectively,  of  the
              computed  eigenvalues.   Complex conjugate pairs of eigenvalues
              appear consecutively with the eigenvalue  having  the  positive
              imaginary part first.

      VL      (output) DOUBLE PRECISION array, dimension (LDVL,N)
              If JOBVL = 'V', the left eigenvectors u(j) are stored one after
              another in the columns of VL, in the same order as their eigen-
              values.   If  JOBVL  =  'N', VL is not referenced.  If the j-th
              eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL.
              If  the  j-th and (j+1)-st eigenvalues form a complex conjugate
              pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
              u(j+1) = VL(:,j) - i*VL(:,j+1).

      LDVL    (input) INTEGER
              The leading dimension of the array VL.  LDVL >= 1; if  JOBVL  =
              'V', LDVL >= N.

      VR      (output) DOUBLE PRECISION array, dimension (LDVR,N)
              If  JOBVR  =  'V',  the  right eigenvectors v(j) are stored one
              after another in the columns of VR, in the same order as  their
              eigenvalues.   If JOBVR = 'N', VR is not referenced.  If the j-
              th eigenvalue is real, then v(j) = VR(:,j), the j-th column  of
```

```
            VR.  If the j-th and (j+1)-st eigenvalues form a complex conju-
            gate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
            v(j+1) = VR(:,j) - i*VR(:,j+1).

      LDVR    (input) INTEGER
            The leading dimension of the array VR.  LDVR >= 1; if  JOBVR  =
            'V', LDVR >= N.

      WORK       (workspace/output)   DOUBLE   PRECISION   array,   dimension
      (MAX(1,LWORK))
            On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

      LWORK   (input) INTEGER
            The  dimension  of the array WORK.  LWORK >= max(1,3*N), and if
            JOBVL = 'V' or JOBVR = 'V', LWORK >=  4*N.   For  good  perfor-
            mance, LWORK must generally be larger.

            If  LWORK  = -1, then a workspace query is assumed; the routine
            only calculates the optimal size of  the  WORK  array,  returns
            this  value  as the first entry of the WORK array, and no error
            message related to LWORK is issued by XERBLA.

      INFO    (output) INTEGER
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an illegal value.
            > 0:  if INFO = i, the QR algorithm failed to compute  all  the
            eigenvalues,  and  no eigenvectors have been computed; elements
            i+1:N of WR and WI contain eigenvalues which have converged.

NAME
       DGEEVX - for an N-by-N real nonsymmetric matrix A, the eigenvalues and,
       optionally, the left and/or right eigenvectors

SYNOPSIS
       SUBROUTINE DGEEVX( BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, WR, WI,  VL,
                          LDVL,  VR,  LDVR,  ILO,  IHI,  SCALE, ABNRM, RCONDE,
                          RCONDV, WORK, LWORK, IWORK, INFO )

           CHARACTER      BALANC, JOBVL, JOBVR, SENSE

           INTEGER        IHI, ILO, INFO, LDA, LDVL, LDVR, LWORK, N

           DOUBLE         PRECISION ABNRM

           INTEGER        IWORK( * )

           DOUBLE         PRECISION A( LDA, * ), RCONDE( *  ),  RCONDV(  *  ),
                          SCALE(  *  ), VL( LDVL, * ), VR( LDVR, * ), WI( * ),
                          WORK( * ), WR( * )

PURPOSE
       DGEEVX computes for an N-by-N real nonsymmetric matrix A, the eigenval-
       ues and, optionally, the left and/or right eigenvectors.

       Optionally  also, it computes a balancing transformation to improve the
       conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE,  and
       ABNRM),  reciprocal condition numbers for the eigenvalues (RCONDE), and
       reciprocal condition numbers for the right
       eigenvectors (RCONDV).

       The right eigenvector v(j) of A satisfies
                        A * v(j) = lambda(j) * v(j)
       where lambda(j) is its eigenvalue.
       The left eigenvector u(j) of A satisfies
                     u(j)**H * A = lambda(j) * u(j)**H
       where u(j)**H denotes the conjugate transpose of u(j).

       The computed eigenvectors are normalized to have Euclidean  norm  equal
       to 1 and largest component real.

       Balancing a matrix means permuting the rows and columns to make it more
```

nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input) CHARACTER*1
Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.
= 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input) CHARACTER*1
= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input) CHARACTER*1
= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input) CHARACTER*1
Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for eigenvalues only;
= 'V': Computed for right eigenvectors only;
= 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N (input) INTEGER
The order of the matrix A. N >= 0.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)

```
        On entry, the N-by-N matrix A.  On exit, A has  been  overwrit-
        ten.   If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur
        form of the balanced version of the input matrix A.

LDA     (input) INTEGER
        The leading dimension of the array A.  LDA >= max(1,N).

WR      (output) DOUBLE PRECISION array, dimension (N)
        WI      (output) DOUBLE PRECISION array, dimension (N)  WR  and
        WI  contain  the real and imaginary parts, respectively, of the
        computed eigenvalues.  Complex conjugate pairs  of  eigenvalues
        will  appear consecutively with the eigenvalue having the posi-
        tive imaginary part first.

VL      (output) DOUBLE PRECISION array, dimension (LDVL,N)
        If JOBVL = 'V', the left eigenvectors u(j) are stored one after
        another in the columns of VL, in the same order as their eigen-
        values.  If JOBVL = 'N', VL is not  referenced.   If  the  j-th
        eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL.
        If the j-th and (j+1)-st eigenvalues form a  complex  conjugate
        pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
        u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL    (input) INTEGER
        The  leading  dimension of the array VL.  LDVL >= 1; if JOBVL =
        'V', LDVL >= N.

VR      (output) DOUBLE PRECISION array, dimension (LDVR,N)
        If JOBVR = 'V', the right  eigenvectors  v(j)  are  stored  one
        after  another in the columns of VR, in the same order as their
        eigenvalues.  If JOBVR = 'N', VR is not referenced.  If the  j-
        th  eigenvalue is real, then v(j) = VR(:,j), the j-th column of
        VR.  If the j-th and (j+1)-st eigenvalues form a complex conju-
        gate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
        v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR    (input) INTEGER
        The leading dimension of the array VR.  LDVR >= 1, and if JOBVR
        = 'V', LDVR >= N.

ILO     (output) INTEGER
        IHI     (output) INTEGER ILO and IHI are integer values  deter-
        mined  when  A  was balanced.  The balanced A(i,j) = 0 if I > J
        and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE   (output) DOUBLE PRECISION array, dimension (N)
        Details of the permutations and scaling  factors  applied  when
        balancing A.  If P(j) is the index of the row and column inter-
        changed with row and column j, and D(j) is the  scaling  factor
        applied  to  row and column j, then SCALE(J) = P(J),    for J =
```

```
        1,...,ILO-1 = D(J),    for J = ILO,...,IHI = P(J)     for  J  =
        IHI+1,...,N.  The order in which the interchanges are made is N
        to IHI+1, then 1 to ILO-1.

ABNRM   (output) DOUBLE PRECISION
        The one-norm of the balanced matrix (the maximum of the sum  of
        absolute values of elements of any column).

RCONDE  (output) DOUBLE PRECISION array, dimension (N)
        RCONDE(j) is the reciprocal condition number of the j-th eigen-
        value.

RCONDV  (output) DOUBLE PRECISION array, dimension (N)
        RCONDV(j) is the reciprocal condition number of the j-th  right
        eigenvector.

WORK       (workspace/output)   DOUBLE   PRECISION   array,   dimension
(MAX(1,LWORK))
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK   (input) INTEGER
        The dimension of the array WORK.   If SENSE = 'N' or 'E', LWORK
        >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LWORK >= 3*N.
        If SENSE = 'V' or 'B', LWORK >= N*(N+6).  For good performance,
        LWORK must generally be larger.

        If LWORK = -1, then a workspace query is assumed;  the  routine
        only  calculates  the  optimal  size of the WORK array, returns
        this value as the first entry of the WORK array, and  no  error
        message related to LWORK is issued by XERBLA.

IWORK   (workspace) INTEGER array, dimension (2*N-2)
        If SENSE = 'N' or 'E', not referenced.

INFO    (output) INTEGER
        = 0:  successful exit
        < 0:  if INFO = -i, the i-th argument had an illegal value.
        >  0:   if INFO = i, the QR algorithm failed to compute all the
        eigenvalues, and no eigenvectors or condition numbers have been
        computed;  elements  1:ILO-1  and  i+1:N  of  WR and WI contain
        eigenvalues which have converged.

*     Compute workspace
*      (Note: Comments in the code beginning "Workspace:" describe the
*       minimal amount of workspace needed at that point in the code,
*       as well as the preferred amount for good performance.
*       NB refers to the optimal block size for the immediately
*       following subroutine, as returned by ILAENV.
*       HSWORK refers to the workspace preferred by DHSEQR, as
*       calculated below. HSWORK is computed assuming ILO=1 and IHI=N,
*       the worst case.)

NAME
       DGEHD2  -  a  real  general  matrix  A to upper Hessenberg form H by an
       orthogonal similarity transformation

SYNOPSIS
       SUBROUTINE DGEHD2( N, ILO, IHI, A, LDA, TAU, WORK, INFO )

           INTEGER        IHI, ILO, INFO, LDA, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEHD2 reduces a real general matrix A to upper Hessenberg form H by an
       orthogonal similarity transformation:  Q' * A * Q = H .
```

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

ILO (input) INTEGER
IHI (input) INTEGER It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to DGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the n by n general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details. LDA (input) INTEGER The leading dimension of the array A. LDA >= max(1,N).

TAU (output) DOUBLE PRECISION array, dimension (N-1)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace) DOUBLE PRECISION array, dimension (N)

INFO (output) INTEGER
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of (ihi-ilo) elementary reflectors

```
Q = H(ilo) H(ilo+1) . . . H(ihi-1).
```

Each H(i) has the form

```
H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with n = 7, ilo = 2 and ihi = 6:

```
on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
(     a   a   a   a   a   a )    (      a   h   h   h   h   a )
```

```
(     a   a   a   a   a   a )    (      h   h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
(     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
(                         a )    (                          a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

NAME
       DGEHRD  -  Reduce a real general matrix A to upper Hessenberg form H by
       an orthogonal similarity transformation

SYNOPSIS
       SUBROUTINE DGEHRD( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        IHI, ILO, INFO, LDA, LWORK, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEHRD reduces a real general matrix A to upper Hessenberg form H by an
       orthogonal similarity transformation:  Q' * A * Q = H .

ARGUMENTS
       N       (input) INTEGER
               The order of the matrix A.  N >= 0.

       ILO     (input) INTEGER
               IHI      (input)  INTEGER It is assumed that A is already upper
               triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI
               are  normally  set by a previous call to DGEBAL; otherwise they
               should be set to 1 and N respectively. See Further Details.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the N-by-N general matrix to be  reduced.   On  exit,
               the upper triangle and the first subdiagonal of A are overwrit-
               ten with the upper Hessenberg matrix H, and the elements  below
               the  first  subdiagonal,  with  the  array  TAU,  represent the
               orthogonal matrix Q as a product of elementary reflectors.  See
               Further Details.  LDA     (input) INTEGER The leading dimension
               of the array A.  LDA >= max(1,N).

       TAU     (output) DOUBLE PRECISION array, dimension (N-1)
               The scalar factors of the elementary  reflectors  (see  Further
               Details).  Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

       WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
               On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

       LWORK   (input) INTEGER
```

```
        The length of the array WORK.  LWORK >= max(1,N).  For  optimum
        performance LWORK >= N*NB, where NB is the optimal blocksize.

        If  LWORK  = -1, then a workspace query is assumed; the routine
        only calculates the optimal size of  the  WORK  array,  returns
        this  value  as the first entry of the WORK array, and no error
        message related to LWORK is issued by XERBLA.

INFO    (output) INTEGER
        = 0:  successful exit
        < 0:  if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS
      The matrix Q is  represented  as  a  product  of  (ihi-ilo)  elementary
      reflectors

         Q = H(ilo) H(ilo+1) . . . H(ihi-1).

      Each H(i) has the form

         H(i) = I - tau * v * v'

      where tau is a real scalar, and v is a real vector with
      v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit
      in A(i+2:ihi,i), and tau in TAU(i).

      The contents of A are illustrated by the following example, with n = 7,
      ilo = 2 and ihi = 6:

      on entry,                        on exit,

      ( a   a   a   a   a   a   a )    (  a   a   h   h   h   h   a )
      (     a   a   a   a   a   a )    (      a   h   h   h   h   a )
      (     a   a   a   a   a   a )    (      h   h   h   h   h   h )
      (     a   a   a   a   a   a )    (      v2  h   h   h   h   h )
      (     a   a   a   a   a   a )    (      v2  v3  h   h   h   h )
      (     a   a   a   a   a   a )    (      v2  v3  v4  h   h   h )
      (                         a )    (                          a )

      where  a denotes an element of the original matrix A, h denotes a modi-
      fied element of the upper Hessenberg matrix H, and vi denotes  an  ele-
      ment of the vector defining H(i).

      See Quintana-Orti and Van  de  Geijn (2005).

NAME
       DGELQ2 - an LQ factorization of a real m by n matrix A

SYNOPSIS
       SUBROUTINE DGELQ2( M, N, A, LDA, TAU, WORK, INFO )

           INTEGER        INFO, LDA, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGELQ2  computes an LQ factorization of a real m by n matrix A: A = L *
```

```
       Q.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the m by n matrix A.  On exit, the  elements  on  and
               below the diagonal of the array contain the m by min(m,n) lower
               trapezoidal matrix L (L is lower triangular if  m  <=  n);  the
               elements  above the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of elementary reflectors  (see
               Further  Details).   LDA     (input) INTEGER The leading dimen-
               sion of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
               The scalar factors of the elementary  reflectors  (see  Further
               Details).

       WORK    (workspace) DOUBLE PRECISION array, dimension (M)

       INFO    (output) INTEGER
               = 0: successful exit
               < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(k) . . . H(2) H(1), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1)  =  0  and v(i) = 1; v(i+1:n) is stored on exit in A(i,i+1:n),
       and tau in TAU(i).

NAME
       DGELQF - an LQ factorization of a real M-by-N matrix A

SYNOPSIS
       SUBROUTINE DGELQF( M, N, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        INFO, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGELQF  computes an LQ factorization of a real M-by-N matrix A: A = L *
       Q.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the M-by-N matrix A.  On exit, the  elements  on  and
               below the diagonal of the array contain the m-by-min(m,n) lower
               trapezoidal matrix L (L is lower triangular if  m  <=  n);  the
               elements  above the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of elementary reflectors  (see
               Further  Details).   LDA     (input) INTEGER The leading dimen-
               sion of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
               The scalar factors of the elementary  reflectors  (see  Further
               Details).

       WORK       (workspace/output)   DOUBLE   PRECISION   array,   dimension
       (MAX(1,LWORK))
```

```
               On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

       LWORK   (input) INTEGER
               The dimension of the array WORK.  LWORK >= max(1,M).  For opti-
               mum performance LWORK >= M*NB, where NB is the  optimal  block-
               size.

               If  LWORK  = -1, then a workspace query is assumed; the routine
               only calculates the optimal size of  the  WORK  array,  returns
               this  value  as the first entry of the WORK array, and no error
               message related to LWORK is issued by XERBLA.

       INFO    (output) INTEGER
               = 0:  successful exit
               < 0:  if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(k) . . . H(2) H(1), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on  exit  in  A(i,i+1:n),
       and tau in TAU(i).

NAME
       DGEQR2 - a QR factorization of a real m by n matrix A

SYNOPSIS
       SUBROUTINE DGEQR2( M, N, A, LDA, TAU, WORK, INFO )

           INTEGER        INFO, LDA, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEQR2  computes  a QR factorization of a real m by n matrix A: A = Q *
       R.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On entry, the m by n matrix A.  On exit, the  elements  on  and
               above the diagonal of the array contain the min(m,n) by n upper
               trapezoidal matrix R (R is upper triangular if  m  >=  n);  the
               elements  below the diagonal, with the array TAU, represent the
               orthogonal matrix Q as a product of elementary reflectors  (see
               Further  Details).   LDA     (input) INTEGER The leading dimen-
               sion of the array A.  LDA >= max(1,M).

       TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
               The scalar factors of the elementary  reflectors  (see  Further
               Details).

       WORK    (workspace) DOUBLE PRECISION array, dimension (N)
```

```
       INFO    (output) INTEGER
               = 0: successful exit
               < 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(1) H(2) . . . H(k), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1)  =  0  and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
       and tau in TAU(i).

NAME
       DGEQRF - a QR factorization of a real M-by-N matrix A

SYNOPSIS
       SUBROUTINE DGEQRF( M, N, A, LDA, TAU, WORK, LWORK, INFO )

           INTEGER        INFO, LDA, LWORK, M, N

           DOUBLE         PRECISION A( LDA, * ), TAU( * ), WORK( * )

PURPOSE
       DGEQRF  computes  a QR factorization of a real M-by-N matrix A: A = Q *
       R.

ARGUMENTS
```

```
M       (input) INTEGER
        The number of rows of the matrix A.  M >= 0.

N       (input) INTEGER
        The number of columns of the matrix A.  N >= 0.

A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
        On entry, the M-by-N matrix A.  On exit, the  elements  on  and
        above the diagonal of the array contain the min(M,N)-by-N upper
        trapezoidal matrix R (R is upper triangular if  m  >=  n);  the
        elements  below the diagonal, with the array TAU, represent the
        orthogonal matrix Q as a product of min(m,n) elementary reflec-
        tors (see Further Details).

LDA     (input) INTEGER
        The leading dimension of the array A.  LDA >= max(1,M).

TAU     (output) DOUBLE PRECISION array, dimension (min(M,N))
        The  scalar  factors  of the elementary reflectors (see Further
        Details).

WORK      (workspace/output)   DOUBLE   PRECISION   array,    dimension
(MAX(1,LWORK))
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK   (input) INTEGER
        The dimension of the array WORK.  LWORK >= max(1,N).  For opti-
        mum  performance  LWORK >= N*NB, where NB is the optimal block-
        size.

        If LWORK = -1, then a workspace query is assumed;  the  routine
        only  calculates  the  optimal  size of the WORK array, returns
        this value as the first entry of the WORK array, and  no  error
        message related to LWORK is issued by XERBLA.

INFO    (output) INTEGER
        = 0:  successful exit
        < 0:  if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS
       The matrix Q is represented as a product of elementary reflectors

          Q = H(1) H(2) . . . H(k), where k = min(m,n).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i-1)  =  0  and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i),
```

and tau in TAU(i).

NAME
       DGESDD - the singular value decomposition (SVD) of a real M-by-N matrix
       A, optionally computing the left and right singular vectors

SYNOPSIS
       SUBROUTINE DGESDD( JOBZ, M, N, A, LDA,  S,  U,  LDU,  VT,  LDVT,  WORK,
                          LWORK, IWORK, INFO )

           CHARACTER      JOBZ

           INTEGER        INFO, LDA, LDU, LDVT, LWORK, M, N

           INTEGER        IWORK( * )

           DOUBLE         PRECISION  A(  LDA,  *  ),  S( * ), U( LDU, * ), VT(
                          LDVT, * ), WORK( * )
```

```
PURPOSE
       DGESDD computes the singular value decomposition (SVD) of a real M-by-N
       matrix A, optionally computing the left and right singular vectors.  If
       singular vectors are desired, it uses a divide-and-conquer algorithm.

       The SVD is written

            A = U * SIGMA * transpose(V)

       where SIGMA is an M-by-N matrix which is zero except for  its  min(m,n)
       diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N
       orthogonal matrix.  The diagonal elements of  SIGMA  are  the  singular
       values  of  A;  they  are  real  and  non-negative, and are returned in
       descending order.  The first min(m,n) columns of U and V are  the  left
       and right singular vectors of A.

       Note that the routine returns VT = V**T, not V.

       The  divide  and  conquer  algorithm  makes very mild assumptions about
       floating point arithmetic. It will work on machines with a guard  digit
       in add/subtract, or on those binary machines without guard digits which
       subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It  could
       conceivably  fail on hexadecimal or decimal machines without guard dig-
       its, but we know of none.

ARGUMENTS
       JOBZ    (input) CHARACTER*1
               Specifies options for computing all or part of the matrix U:
               = 'A':  all M columns of U and all N rows of V**T are  returned
               in the arrays U and VT; = 'S':  the first min(M,N) columns of U
               and the first min(M,N) rows of V**T are returned in the  arrays
               U and VT; = 'O':  If M >= N, the first N columns of U are over-
               written on the array A and all rows of V**T are returned in the
               array VT; otherwise, all columns of U are returned in the array
               U and the first M rows of V**T are overwritten in the array  A;
               = 'N':  no columns of U or rows of V**T are computed.

       M       (input) INTEGER
               The number of rows of the input matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the input matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On  entry,  the M-by-N matrix A.  On exit, if JOBZ = 'O',  A is
               overwritten with the first N columns of U  (the  left  singular
               vectors,  stored  columnwise)  if M >= N; A is overwritten with
               the first M rows of V**T (the right  singular  vectors,  stored
```

```
        rowwise)  otherwise.   if  JOBZ .ne. 'O', the contents of A are
        destroyed.

LDA     (input) INTEGER
        The leading dimension of the array A.  LDA >= max(1,M).

S       (output) DOUBLE PRECISION array, dimension (min(M,N))
        The singular values of A, sorted so that S(i) >= S(i+1).

U       (output) DOUBLE PRECISION array, dimension (LDU,UCOL)
        UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M,N)
        if  JOBZ  = 'S'.  If JOBZ = 'A' or JOBZ = 'O' and M < N, U con-
        tains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains
        the  first  min(M,N)  columns  of U (the left singular vectors,
        stored columnwise); if JOBZ = 'O' and M >= N, or JOBZ = 'N',  U
        is not referenced.

LDU     (input) INTEGER
        The  leading dimension of the array U.  LDU >= 1; if JOBZ = 'S'
        or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT      (output) DOUBLE PRECISION array, dimension (LDVT,N)
        If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the  N-by-N
        orthogonal  matrix  V**T;  if JOBZ = 'S', VT contains the first
        min(M,N) rows of V**T (the right singular vectors, stored  row-
        wise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not refer-
        enced.

LDVT    (input) INTEGER
        The leading dimension of the array VT.  LDVT >= 1;  if  JOBZ  =
        'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >=
        min(M,N).

WORK      (workspace/output)   DOUBLE   PRECISION   array,    dimension
(MAX(1,LWORK))
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK   (input) INTEGER
        The dimension of the array WORK. LWORK >= 1.  If  JOBZ  =  'N',
        LWORK >= 3*min(M,N) + max(max(M,N),7*min(M,N)).  If JOBZ = 'O',
        LWORK            >=            3*min(M,N)*min(M,N)            +
        max(max(M,N),5*min(M,N)*min(M,N)+4*min(M,N)).  If JOBZ = 'S' or
        'A'        LWORK        >=        3*min(M,N)*min(M,N)         +
        max(max(M,N),4*min(M,N)*min(M,N)+4*min(M,N)).  For good perfor-
        mance, LWORK should generally be larger.  If  LWORK  =  -1  but
        other  input  arguments  are legal, WORK(1) returns the optimal
        LWORK.

IWORK   (workspace) INTEGER array, dimension (8*min(M,N))
```

```
      INFO    (output) INTEGER
              = 0:  successful exit.
              < 0:  if INFO = -i, the i-th argument had an illegal value.
              > 0:  DBDSDC did not converge, updating process failed.

NAME
       DGESVD - the singular value decomposition (SVD) of a real M-by-N matrix
       A, optionally computing the left and/or right singular vectors

SYNOPSIS
       SUBROUTINE DGESVD( JOBU, JOBVT, M, N, A, LDA,  S,  U,  LDU,  VT,  LDVT,
                          WORK, LWORK, INFO )

           CHARACTER      JOBU, JOBVT

           INTEGER        INFO, LDA, LDU, LDVT, LWORK, M, N

           DOUBLE         PRECISION  A(  LDA,  *  ),  S( * ), U( LDU, * ), VT(
                          LDVT, * ), WORK( * )

  Purpose
  =======

  DGESVD computes the singular value decomposition (SVD) of a real
  M-by-N matrix A, optionally computing the left and/or right singular
  vectors. The SVD is written

       A = U * SIGMA * transpose(V)

  where SIGMA is an M-by-N matrix which is zero except for its
  min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and
  V is an N-by-N orthogonal matrix.  The diagonal elements of SIGMA
  are the singular values of A; they are real and non-negative, and
  are returned in descending order.  The first min(m,n) columns of
  U and V are the left and right singular vectors of A.
```

```
Note that the routine returns V**T, not V.

Arguments
=========

JOBU    (input) CHARACTER*1
        Specifies options for computing all or part of the matrix U:
        = 'A':  all M columns of U are returned in array U:
        = 'S':  the first min(m,n) columns of U (the left singular
                vectors) are returned in the array U;
        = 'O':  the first min(m,n) columns of U (the left singular
                vectors) are overwritten on the array A;
        = 'N':  no columns of U (no left singular vectors) are
                computed.

JOBVT   (input) CHARACTER*1
        Specifies options for computing all or part of the matrix
        V**T:
        = 'A':  all N rows of V**T are returned in the array VT;
        = 'S':  the first min(m,n) rows of V**T (the right singular
                vectors) are returned in the array VT;
        = 'O':  the first min(m,n) rows of V**T (the right singular
                vectors) are overwritten on the array A;
        = 'N':  no rows of V**T (no right singular vectors) are
                computed.

        JOBVT and JOBU cannot both be 'O'.

M       (input) INTEGER
        The number of rows of the input matrix A.  M >= 0.

N       (input) INTEGER
        The number of columns of the input matrix A.  N >= 0.

A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
        On entry, the M-by-N matrix A.
        On exit,
        if JOBU = 'O',  A is overwritten with the first min(m,n)
                        columns of U (the left singular vectors,
                        stored columnwise);
        if JOBVT = 'O', A is overwritten with the first min(m,n)
                        rows of V**T (the right singular vectors,
                        stored rowwise);
        if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A
                        are destroyed.

LDA     (input) INTEGER
        The leading dimension of the array A.  LDA >= max(1,M).

S       (output) DOUBLE PRECISION array, dimension (min(M,N))
```

```
        The singular values of A, sorted so that S(i) >= S(i+1).

U       (output) DOUBLE PRECISION array, dimension (LDU,UCOL)
        (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'.
        If JOBU = 'A', U contains the M-by-M orthogonal matrix U;
        if JOBU = 'S', U contains the first min(m,n) columns of U
        (the left singular vectors, stored columnwise);
        if JOBU = 'N' or 'O', U is not referenced.

LDU     (input) INTEGER
        The leading dimension of the array U.  LDU >= 1; if
        JOBU = 'S' or 'A', LDU >= M.

VT      (output) DOUBLE PRECISION array, dimension (LDVT,N)
        If JOBVT = 'A', VT contains the N-by-N orthogonal matrix
        V**T;
        if JOBVT = 'S', VT contains the first min(m,n) rows of
        V**T (the right singular vectors, stored rowwise);
        if JOBVT = 'N' or 'O', VT is not referenced.

LDVT    (input) INTEGER
        The leading dimension of the array VT.  LDVT >= 1; if
        JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
        On exit, if INFO = 0, WORK(1) returns the optimal LWORK;
        if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged
        superdiagonal elements of an upper bidiagonal matrix B
        whose diagonal is in S (not necessarily sorted). B
        satisfies A = U * B * VT, so it has the same singular values
        as A, and singular vectors related by U and VT.

LWORK   (input) INTEGER
        The dimension of the array WORK. LWORK >= 1.
        LWORK >= MAX(3*MIN(M,N)+MAX(M,N),5*MIN(M,N)).
        For good performance, LWORK should generally be larger.

        If LWORK = -1, then a workspace query is assumed; the routine
        only calculates the optimal size of the WORK array, returns
        this value as the first entry of the WORK array, and no error
        message related to LWORK is issued by XERBLA.

INFO    (output) INTEGER
        = 0:  successful exit.
        < 0:  if INFO = -i, the i-th argument had an illegal value.
        > 0:  if DBDSQR did not converge, INFO specifies how many
              superdiagonals of an intermediate bidiagonal form B
              did not converge to zero. See the description of WORK
              above for details.

NAME
       DGESV - the solution to a real system of linear equations  A * X = B,

SYNOPSIS
       SUBROUTINE DGESV( N, NRHS, A, LDA, IPIV, B, LDB, INFO )

           INTEGER       INFO, LDA, LDB, N, NRHS

           INTEGER       IPIV( * )

           DOUBLE        PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
       DGESV computes the solution to a real system of linear equations
          A  *  X  =  B, where A is an N-by-N matrix and X and B are N-by-NRHS
       matrices.

       The LU decomposition with partial pivoting and row interchanges is used
       to factor A as
          A = P * L * U,
       where  P  is a permutation matrix, L is unit lower triangular, and U is
       upper triangular.  The factored form of A is then  used  to  solve  the
       system of equations A * X = B.

ARGUMENTS
       N       (input) INTEGER
               The  number  of linear equations, i.e., the order of the matrix
```

```
          A.  N >= 0.

NRHS      (input) INTEGER
          The number of right hand sides, i.e., the number of columns  of
          the matrix B.  NRHS >= 0.

A         (input/output) DOUBLE PRECISION array, dimension (LDA,N)
          On  entry,  the N-by-N coefficient matrix A.  On exit, the fac-
          tors L and U from the factorization A = P*L*U; the unit  diago-
          nal elements of L are not stored.

LDA       (input) INTEGER
          The leading dimension of the array A.  LDA >= max(1,N).

IPIV      (output) INTEGER array, dimension (N)
          The  pivot  indices that define the permutation matrix P; row i
          of the matrix was interchanged with row IPIV(i).

B         (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)
          On entry, the N-by-NRHS matrix of right hand side matrix B.  On
          exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB       (input) INTEGER
          The leading dimension of the array B.  LDB >= max(1,N).

INFO      (output) INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an illegal value
          >  0:   if INFO = i, U(i,i) is exactly zero.  The factorization
          has been completed, but the factor U is  exactly  singular,  so
          the solution could not be computed.
```

NAME
       DGETF2 - an LU factorization of a general m-by-n matrix A using partial
       pivoting with row interchanges

SYNOPSIS
```

```
SUBROUTINE DGETF2( M, N, A, LDA, IPIV, INFO )

    INTEGER        INFO, LDA, M, N

    INTEGER        IPIV( * )

    DOUBLE         PRECISION A( LDA, * )
```

PURPOSE

DGETF2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) INTEGER
The number of rows of the matrix A. M >= 0.

N (input) INTEGER
The number of columns of the matrix A. N >= 0.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input) INTEGER
The leading dimension of the array A. LDA >= max(1,M).

IPIV (output) INTEGER array, dimension (min(M,N))
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output) INTEGER
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

NAME
       DGETRF - an LU factorization of a general M-by-N matrix A using partial
       pivoting with row interchanges

SYNOPSIS
       SUBROUTINE DGETRF( M, N, A, LDA, IPIV, INFO )

           INTEGER        INFO, LDA, M, N

           INTEGER        IPIV( * )

           DOUBLE         PRECISION A( LDA, * )

PURPOSE
       DGETRF computes an LU factorization of a general M-by-N matrix A  using
       partial pivoting with row interchanges.

       The factorization has the form
          A = P * L * U
       where P is a permutation matrix, L is lower triangular with unit diago-
       nal elements (lower trapezoidal if m > n), and U  is  upper  triangular
       (upper trapezoidal if m < n).

       This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS
       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input/output) DOUBLE PRECISION array, dimension (LDA,N)
               On  entry, the M-by-N matrix to be factored.  On exit, the fac-
               tors L and U from the factorization A = P*L*U; the unit  diago-
               nal elements of L are not stored.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,M).

       IPIV    (output) INTEGER array, dimension (min(M,N))
```

```
              The  pivot indices; for 1 <= i <= min(M,N), row i of the matrix
              was interchanged with row IPIV(i).

       INFO    (output) INTEGER
               = 0:  successful exit
               < 0:  if INFO = -i, the i-th argument had an illegal value
               > 0:  if INFO = i, U(i,i) is exactly  zero.  The  factorization
               has  been  completed, but the factor U is exactly singular, and
               division by zero will occur if it is used to solve a system  of
               equations.
```

NAME
       DGETRS  -  a system of linear equations  A * X = B or A' * X = B with a
       general N-by-N matrix A using the LU factorization computed by DGETRF

SYNOPSIS
       SUBROUTINE DGETRS( TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO )

           CHARACTER      TRANS

           INTEGER        INFO, LDA, LDB, N, NRHS

           INTEGER        IPIV( * )

           DOUBLE         PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
       DGETRS solves a system of linear equations
          A * X = B  or  A' * X = B with a general N-by-N matrix A  using  the
       LU factorization computed by DGETRF.

ARGUMENTS
       TRANS   (input) CHARACTER*1
               Specifies the form of the system of equations:
               = 'N':  A * X = B  (No transpose)
               = 'T':  A'* X = B  (Transpose)
               = 'C':  A'* X = B  (Conjugate transpose = Transpose)

       N       (input) INTEGER
               The order of the matrix A.  N >= 0.

       NRHS    (input) INTEGER
               The  number of right hand sides, i.e., the number of columns of
               the matrix B.  NRHS >= 0.

       A       (input) DOUBLE PRECISION array, dimension (LDA,N)
               The factors L and U from the factorization A =  P*L*U  as  com-
               puted by DGETRF.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,N).

       IPIV    (input) INTEGER array, dimension (N)
```

```
              The pivot indices from DGETRF; for 1<=i<=N, row i of the matrix
              was interchanged with row IPIV(i).

      B       (input/output) DOUBLE PRECISION array, dimension (LDB,NRHS)
              On entry, the right hand side matrix B.  On exit, the  solution
              matrix X.

      LDB     (input) INTEGER
              The leading dimension of the array B.  LDB >= max(1,N).

      INFO    (output) INTEGER
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an illegal value
```

NAME
       DHSEQR - compute the eigenvalues of a Hessenberg matrix H  and, option-
       ally, the matrices T and Z from the Schur decomposition  H = Z T  Z**T,
       where T is an upper quasi-triangular matrix (the  Schur form), and Z is
       the orthogonal matrix of Schur vectors

       Optionally Z may be postmultiplied into an input orthogonal matrix Q,
       so that this routine can give the Schur factorization of a matrix A
       which has been reduced to the Hessenberg form H by the orthogonal
       matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.
```

```
SYNOPSIS
       SUBROUTINE DHSEQR( JOB, COMPZ, N, ILO, IHI, H, LDH,  WR,  WI,  Z,  LDZ,
                          WORK, LWORK, INFO )

           INTEGER        IHI, ILO, INFO, LDH, LDZ, LWORK, N

           CHARACTER      COMPZ, JOB

           DOUBLE         PRECISION  H( LDH, * ), WI( * ), WORK( * ), WR( * ),
                          Z( LDZ, * )

PURPOSE
          DHSEQR computes the eigenvalues of a Hessenberg matrix H
          and, optionally, the matrices T and Z from the Schur decomposition
          H = Z T Z**T, where T is an upper quasi-triangular matrix (the
          Schur form), and Z is the orthogonal matrix of Schur vectors.

          Optionally Z may be postmultiplied into an input orthogonal
          matrix Q so that this routine can give the Schur factorization
          of a matrix A which has been reduced to the Hessenberg form H
          by the orthogonal matrix Q:  A = Q*H*Q**T = (QZ)*T*(QZ)**T.

ARGUMENTS
  JOB     (input) CHARACTER*1
          = 'E':  compute eigenvalues only;
          = 'S':  compute eigenvalues and the Schur form T.

  COMPZ   (input) CHARACTER*1
          = 'N':  no Schur vectors are computed;
          = 'I':  Z is initialized to the unit matrix and the matrix Z
                  of Schur vectors of H is returned;
          = 'V':  Z must contain an orthogonal matrix Q on entry, and
                  the product Q*Z is returned.

  N       (input) INTEGER
          The order of the matrix H.  N >= 0.

  ILO     (input) INTEGER
  IHI     (input) INTEGER
          It is assumed that H is already upper triangular in rows
          and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally
          set by a previous call to DGEBAL, and then passed to SGEHRD
          when the matrix output by DGEBAL is reduced to Hessenberg
          form. Otherwise ILO and IHI should be set to 1 and N
          respectively.
          1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

  H       (input/output) DOUBLE PRECISION array, dimension (LDH,N)
```

```
         On entry, the upper Hessenberg matrix H.
         On exit, if JOB = 'S', H contains the upper quasi-triangular
         matrix T from the Schur decomposition (the Schur form);
         2-by-2 diagonal blocks (corresponding to complex conjugate
         pairs of eigenvalues) are returned in standard form, with
         H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1) < 0. If JOB = 'E',
         the contents of H are unspecified on exit.

 LDH     (input) INTEGER
         The leading dimension of the array H. LDH >= max(1,N).

 WR      (output) DOUBLE PRECISION array, dimension (N)
 WI      (output) DOUBLE PRECISION array, dimension (N)
         The real and imaginary parts, respectively, of the computed
         eigenvalues. If two eigenvalues are computed as a complex
         conjugate pair, they are stored in consecutive elements of
         WR and WI, say the i-th and (i+1)th, with WI(i) > 0 and
         WI(i+1) < 0. If JOB = 'S', the eigenvalues are stored in the
         same order as on the diagonal of the Schur form returned in
         H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2
         diagonal block, WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and
         WI(i+1) = -WI(i).

 Z       (input/output) DOUBLE PRECISION array, dimension (LDZ,N)
         If COMPZ = 'N': Z is not referenced.
         If COMPZ = 'I': on entry, Z need not be set, and on exit, Z
         contains the orthogonal matrix Z of the Schur vectors of H.
         If COMPZ = 'V': on entry Z must contain an N-by-N matrix Q,
         which is assumed to be equal to the unit matrix except for
         the submatrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z.
         Normally Q is the orthogonal matrix generated by DORGHR after
         the call to DGEHRD which formed the Hessenberg matrix H.

 LDZ     (input) INTEGER
         The leading dimension of the array Z.
         LDZ >= max(1,N) if COMPZ = 'I' or 'V'; LDZ >= 1 otherwise.

 WORK    (workspace/output) DOUBLE PRECISION array, dimension (LWORK)
         On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

 LWORK   (input) INTEGER
         The dimension of the array WORK.  LWORK >= max(1,N).

         If LWORK = -1, then a workspace query is assumed; the routine
         only calculates the optimal size of the WORK array, returns
         this value as the first entry of the WORK array, and no error
         message related to LWORK is issued by XERBLA.

 INFO    (output) INTEGER
         = 0:  successful exit
```

```
         < 0:  if INFO = -i, the i-th argument had an illegal value
         > 0:  if INFO = i, DHSEQR failed to compute all of the
               eigenvalues in a total of 30*(IHI-ILO+1) iterations;
               elements 1:ilo-1 and i+1:n of WR and WI contain those
               eigenvalues which have been successfully computed.
```

NAME
       DLABAD  - a input the values computed by DLAMCH for underflow and over-
       flow, and returns the square root of each of these values if the log of
       LARGE is sufficiently large

SYNOPSIS
       SUBROUTINE DLABAD( SMALL, LARGE )

           DOUBLE         PRECISION LARGE, SMALL

PURPOSE
       DLABAD  takes  as input the values computed by DLAMCH for underflow and
       overflow, and returns the square root of each of these  values  if  the
       log  of  LARGE  is  sufficiently large.  This subroutine is intended to
       identify machines with a large exponent range, such as the  Crays,  and
       redefine  the  underflow  and overflow limits to be the square roots of
```

```
       the values computed by  DLAMCH.   This  subroutine  is  needed  because
       DLAMCH does not compensate for poor arithmetic in the upper half of the
       exponent range, as is found on a Cray.

ARGUMENTS
       SMALL   (input/output) DOUBLE PRECISION
               On entry, the underflow threshold as computed  by  DLAMCH.   On
               exit, if LOG10(LARGE) is sufficiently large, the square root of
               SMALL, otherwise unchanged.

       LARGE   (input/output) DOUBLE PRECISION
               On entry, the overflow threshold as  computed  by  DLAMCH.   On
               exit, if LOG10(LARGE) is sufficiently large, the square root of
               LARGE, otherwise unchanged.

NAME
       DLABRD  - the first NB rows and columns of a real general m by n matrix
```

A to upper or lower bidiagonal form by an orthogonal transformation Q' * A * P, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A

SYNOPSIS

```
SUBROUTINE DLABRD( M, N, NB, A, LDA, D, E, TAUQ, TAUP, X, LDX, Y, LDY )

    INTEGER        LDA, LDX, LDY, M, N, NB

    DOUBLE         PRECISION  A(  LDA,  * ), D( * ), E( * ), TAUP( * ),
                   TAUQ( * ), X( LDX, * ), Y( LDY, * )
```

PURPOSE

DLABRD reduces the first NB rows and columns of a real general m by n matrix A to upper or lower bidiagonal form by an orthogonal transformation Q' * A * P, and returns the matrices X and Y which are needed to apply the transformation to the unreduced part of A.

If m >= n, A is reduced to upper bidiagonal form; if m < n, to lower bidiagonal form.

This is an auxiliary routine called by DGEBRD

ARGUMENTS

M (input) INTEGER
The number of rows in the matrix A.

N (input) INTEGER
The number of columns in the matrix A.

NB (input) INTEGER
The number of leading rows and columns of A to be reduced.

A (input/output) DOUBLE PRECISION array, dimension (LDA,N)
On entry, the m by n general matrix to be reduced. On exit, the first NB rows and columns of the matrix are overwritten; the rest of the array is unchanged. If m >= n, elements on and below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors; and elements above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. If m < n, elements below the diagonal in the first NB columns, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and elements on and above the diagonal in the first NB rows, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details. LDA (input) INTEGER The leading dimension of the array A. LDA >= max(1,M).

```
D       (output) DOUBLE PRECISION array, dimension (NB)
        The diagonal elements of the first NB rows and columns  of  the
        reduced matrix.  D(i) = A(i,i).

E       (output) DOUBLE PRECISION array, dimension (NB)
        The  off-diagonal  elements of the first NB rows and columns of
        the reduced matrix.

TAUQ    (output) DOUBLE PRECISION array dimension (NB)
        The scalar factors of the elementary reflectors which represent
        the orthogonal matrix Q. See Further Details.  TAUP    (output)
        DOUBLE PRECISION array, dimension (NB) The  scalar  factors  of
        the elementary reflectors which represent the orthogonal matrix
        P. See Further  Details.   X        (output)  DOUBLE  PRECISION
        array,  dimension  (LDX,NB)  The  m-by-nb  matrix X required to
        update the unreduced part of A.

LDX     (input) INTEGER
        The leading dimension of the array X. LDX >= M.

Y       (output) DOUBLE PRECISION array, dimension (LDY,NB)
        The n-by-nb matrix Y required to update the unreduced  part  of
        A.

LDY     (input) INTEGER
        The leading dimension of the array Y. LDY >= N.

FURTHER DETAILS
        The  matrices Q and P are represented as products of elementary reflec-
        tors:

           Q = H(1) H(2) . . . H(nb)  and  P = G(1) G(2) . . . G(nb)

        Each H(i) and G(i) has the form:

           H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

        where tauq and taup are real scalars, and v and u are real vectors.

        If m >= n, v(1:i-1) = 0, v(i) = 1, and v(i:m)  is  stored  on  exit  in
        A(i:m,i);  u(1:i)  =  0,  u(i+1) = 1, and u(i+1:n) is stored on exit in
        A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

        If m < n, v(1:i) = 0, v(i+1) = 1, and v(i+1:m) is  stored  on  exit  in
        A(i+2:m,i);  u(1:i-1)  =  0,  u(i) = 1, and u(i:n) is stored on exit in
        A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

        The elements of the vectors v and u together form the m-by-nb matrix  V
        and  the nb-by-n matrix U' which are needed, with X and Y, to apply the
```

```
transformation to the unreduced part  of  the  matrix,  using  a  block
update of the form:  A := A - V*Y' - X*U'.

The  contents  of  A  on exit are illustrated by the following examples
with nb = 2:

m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

  (  1   1   u1  u1  u1 )           (  1   u1  u1  u1  u1  u1 )
  (  v1  1   1   u2  u2 )           (  1   1   u2  u2  u2  u2 )
  (  v1  v2  a   a   a  )           (  v1  1   a   a   a   a  )
  (  v1  v2  a   a   a  )           (  v1  v2  a   a   a   a  )
  (  v1  v2  a   a   a  )           (  v1  v2  a   a   a   a  )
  (  v1  v2  a   a   a  )

where a denotes an element of the original matrix which  is  unchanged,
vi denotes an element of the vector defining H(i), and ui an element of
the vector defining G(i).

NAME
       DLACON - the 1-norm of a square, real matrix A

SYNOPSIS
       SUBROUTINE DLACON( N, V, X, ISGN, EST, KASE )

           INTEGER        KASE, N

           DOUBLE         PRECISION EST

           INTEGER        ISGN( * )

           DOUBLE         PRECISION V( * ), X( * )

PURPOSE
       DLACON estimates the 1-norm of a square, real matrix A.  Reverse commu-
       nication is used for evaluating matrix-vector products.

ARGUMENTS
       N      (input) INTEGER
              The order of the matrix.  N >= 1.

       V      (workspace) DOUBLE PRECISION array, dimension (N)
              On the final return, V = A*W,  where  EST =  norm(V)/norm(W)  (W
              is not returned).

       X      (input/output) DOUBLE PRECISION array, dimension (N)
              On  an  intermediate  return,  X should be overwritten by A * X,
              if KASE=1, A' * X,  if KASE=2, and DLACON must be re-called with
              all the other parameters unchanged.

       ISGN   (workspace) INTEGER array, dimension (N)

       EST    (input/output) DOUBLE PRECISION
              On  entry  with  KASE  =  1  or  2  and  JUMP = 3, EST should be
              unchanged from the previous call to DLACON.  On exit, EST is  an
              estimate (a lower bound) for norm(A).

       KASE   (input/output) INTEGER
              On the initial call to DLACON, KASE should be 0.  On an interme-
              diate return, KASE will be 1 or 2, indicating whether  X  should
              be  overwritten  by  A * X  or A' * X.  On the final return from
              DLACON, KASE will again be 0.
```

```

NAME
       DLACPY - all or part of a two-dimensional matrix A to another matrix B

SYNOPSIS
       SUBROUTINE DLACPY( UPLO, M, N, A, LDA, B, LDB )

           CHARACTER      UPLO

           INTEGER        LDA, LDB, M, N

           DOUBLE         PRECISION A( LDA, * ), B( LDB, * )

PURPOSE
       DLACPY  copies  all  or  part  of a two-dimensional matrix A to another
       matrix B.

ARGUMENTS
       UPLO    (input) CHARACTER*1
               Specifies the part of the matrix A to be copied to B.   =  'U':
               Upper triangular part
               = 'L':      Lower triangular part
               Otherwise:  All of the matrix A

       M       (input) INTEGER
               The number of rows of the matrix A.  M >= 0.

       N       (input) INTEGER
               The number of columns of the matrix A.  N >= 0.

       A       (input) DOUBLE PRECISION array, dimension (LDA,N)
               The m by n matrix A.  If UPLO = 'U', only the upper triangle or
               trapezoid is accessed; if UPLO = 'L', only the  lower  triangle
               or trapezoid is accessed.

       LDA     (input) INTEGER
               The leading dimension of the array A.  LDA >= max(1,M).

       B       (output) DOUBLE PRECISION array, dimension (LDB,N)
               On exit, B = A in the locations specified by UPLO.

       LDB     (input) INTEGER
```

```
              The leading dimension of the array B.  LDB >= max(1,M).
```

NAME
  DLADIV performs complex division in  real arithmetic

                         a + i*b
             p + i*q = ---------
                         c + i*d

  The algorithm is due to Robert L. Smith and can be found
  in D. Knuth, The art of Computer Programming, Vol.2, p.195

 Arguments
 =========

  A       (input) DOUBLE PRECISION
  B       (input) DOUBLE PRECISION
  C       (input) DOUBLE PRECISION
```

```
 D       (input) DOUBLE PRECISION
         The scalars a, b, c, and d in the above expression.

 P       (output) DOUBLE PRECISION
 Q       (output) DOUBLE PRECISION
         The scalars p and q in the above expression.
```

==================================================================
dlaed6 examples
==================================================================

==================================================================
Man Page Details
==================================================================

 Purpose
 =======

  DLAED6 computes the positive or negative root (closest to the origin)
  of
                   z(1)        z(2)        z(3)
  f(x) =   rho + --------- + ---------- + ---------
                  d(1)-x      d(2)-x      d(3)-x

  It is assumed that

        if ORGATI = .true. the root is between d(2) and d(3);
        otherwise it is between d(1) and d(2)

  This routine will be called by DLAED4 when necessary. In most cases,
  the root sought is the smallest in magnitude, though it might not be
  in some extremely rare situations.

  Arguments
  =========

  KNITER       (input) INTEGER
               Refer to DLAED4 for its significance.
```

```
 ORGATI       (input) LOGICAL
              If ORGATI is true, the needed root is between d(2) and
              d(3); otherwise it is between d(1) and d(2).  See
              DLAED4 for further details.

 RHO          (input) DOUBLE PRECISION
              Refer to the equation f(x) above.

 D            (input) DOUBLE PRECISION array, dimension (3)
              D satisfies d(1) < d(2) < d(3).

 Z            (input) DOUBLE PRECISION array, dimension (3)
              Each of the elements in z must be positive.

 FINIT        (input) DOUBLE PRECISION
              The value of f at 0. It is more accurate than the one
              evaluated inside this routine (if someone wants to do
              so).

 TAU          (output) DOUBLE PRECISION
              The root of the equation f(x).

 INFO         (output) INTEGER
              = 0: successful exit
              > 0: if INFO = 1, failure to converge

Further Details
===============

NAME
       DLAEXC  -  adjacent  diagonal  blocks T11 and T22 of order 1 or 2 in an
       upper quasi-triangular matrix T by an orthogonal similarity transforma-
       tion

SYNOPSIS
       SUBROUTINE DLAEXC( WANTQ, N, T, LDT, Q, LDQ, J1, N1, N2, WORK, INFO )
```

```
      LOGICAL        WANTQ

      INTEGER        INFO, J1, LDQ, LDT, N, N1, N2

      DOUBLE         PRECISION Q( LDQ, * ), T( LDT, * ), WORK( * )
```

PURPOSE

DLAEXC swaps adjacent diagonal blocks T11 and T22 of order 1 or 2 in an upper quasi-triangular matrix T by an orthogonal similarity transformation.

T must be in Schur canonical form, that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elemnts equal and its off-diagonal elements of opposite sign.

ARGUMENTS

WANTQ (input) LOGICAL
= .TRUE. : accumulate the transformation in the matrix Q;
= .FALSE.: do not accumulate the transformation.

N (input) INTEGER
The order of the matrix T. N >= 0.

T (input/output) DOUBLE PRECISION array, dimension (LDT,N)
On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, the updated matrix T, again in Schur canonical form.

LDT (input) INTEGER
The leading dimension of the array T. LDT >= max(1,N).

Q (input/output) DOUBLE PRECISION array, dimension (LDQ,N)
On entry, if WANTQ is .TRUE., the orthogonal matrix Q. On exit, if WANTQ is .TRUE., the updated matrix Q. If WANTQ is .FALSE., Q is not referenced.

LDQ (input) INTEGER
The leading dimension of the array Q. LDQ >= 1; and if WANTQ is .TRUE., LDQ >= N.

J1 (input) INTEGER
The index of the first row of the first block T11.

N1 (input) INTEGER
The order of the first block T11. N1 = 0, 1 or 2.

N2 (input) INTEGER
The order of the second block T22. N2 = 0, 1 or 2.

```
WORK    (workspace) DOUBLE PRECISION array, dimension (N)

INFO    (output) INTEGER
        = 0: successful exit
        = 1: the transformed matrix T would be too far from Schur form;
        the blocks are not swapped and T and Q are unchanged.
```

NAME
       DLAHQR - An auxiliary routine called by DHSEQR to update the  eigenval-
       ues and Schur decomposition already computed  by  DHSEQR,  by   dealing
       with the Hessenberg submatrix in rows and columns ILO to IHI

SYNOPSIS
       SUBROUTINE DLAHQR( WANTT,  WANTZ,  N,  ILO,  IHI, H, LDH, WR, WI, ILOZ,
                          IHIZ, Z, LDZ, INFO )

           INTEGER        IHI, IHIZ, ILO, ILOZ, INFO, LDH, LDZ, N

           LOGICAL        WANTT, WANTZ

           DOUBLE         PRECISION H( LDH, * ), WI( * ), WR( * ), Z( LDZ, * )

 Purpose
 =======

  DLAHQR is an auxiliary routine called by DHSEQR to update the
  eigenvalues and Schur decomposition already computed by DHSEQR, by
  dealing with the Hessenberg submatrix in rows and columns ILO to IHI.

 Arguments
 =========

  WANTT   (input) LOGICAL
          = .TRUE. : the full Schur form T is required;
          = .FALSE.: only eigenvalues are required.

  WANTZ   (input) LOGICAL
          = .TRUE. : the matrix of Schur vectors Z is required;
```

```
        = .FALSE.: Schur vectors are not required.

N       (input) INTEGER
        The order of the matrix H.  N >= 0.

ILO     (input) INTEGER
IHI     (input) INTEGER
        It is assumed that H is already upper quasi-triangular in
        rows and columns IHI+1:N, and that H(ILO,ILO-1) = 0 (unless
        ILO = 1). DLAHQR works primarily with the Hessenberg
        submatrix in rows and columns ILO to IHI, but applies
        transformations to all of H if WANTT is .TRUE..
        1 <= ILO <= max(1,IHI); IHI <= N.

H       (input/output) DOUBLE PRECISION array, dimension (LDH,N)
        On entry, the upper Hessenberg matrix H.
        On exit, if WANTT is .TRUE., H is upper quasi-triangular in
        rows and columns ILO:IHI, with any 2-by-2 diagonal blocks in
        standard form. If WANTT is .FALSE., the contents of H are
        unspecified on exit.

LDH     (input) INTEGER
        The leading dimension of the array H. LDH >= max(1,N).

WR      (output) DOUBLE PRECISION array, dimension (N)
WI      (output) DOUBLE PRECISION array, dimension (N)
        The real and imaginary parts, respectively, of the computed
        eigenvalues ILO to IHI are stored in the corresponding
        elements of WR and WI. If two eigenvalues are computed as a
        complex conjugate pair, they are stored in consecutive
        elements of WR and WI, say the i-th and (i+1)th, with
        WI(i) > 0 and WI(i+1) < 0. If WANTT is .TRUE., the
        eigenvalues are stored in the same order as on the diagonal
        of the Schur form returned in H, with WR(i) = H(i,i), and, if
        H(i:i+1,i:i+1) is a 2-by-2 diagonal block,
        WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

ILOZ    (input) INTEGER
IHIZ    (input) INTEGER
        Specify the rows of Z to which transformations must be
        applied if WANTZ is .TRUE..
        1 <= ILOZ <= ILO; IHI <= IHIZ <= N.

Z       (input/output) DOUBLE PRECISION array, dimension (LDZ,N)
        If WANTZ is .TRUE., on entry Z must contain the current
        matrix Z of transformations accumulated by DHSEQR, and on
        exit Z has been updated; transformations are applied only to
        the submatrix Z(ILOZ:IHIZ,ILO:IHI).
        If WANTZ is .FALSE., Z is not referenced.
```

```
 LDZ     (input) INTEGER
         The leading dimension of the array Z. LDZ >= max(1,N).

 INFO    (output) INTEGER
         = 0: successful exit
         > 0: DLAHQR failed to compute all the eigenvalues ILO to IHI
              in a total of 30*(IHI-ILO+1) iterations; if INFO = i,
              elements i+1:ihi of WR and WI contain those eigenvalues
              which have been successfully computed.

NAME
       DLAHRD  -  the first NB columns of a real general n-by-(n-k+1) matrix A
       so that elements below the k-th subdiagonal are zero

SYNOPSIS
       SUBROUTINE DLAHRD( N, K, NB, A, LDA, TAU, T, LDT, Y, LDY )

           INTEGER        K, LDA, LDT, LDY, N, NB

           DOUBLE         PRECISION A( LDA, * ), T( LDT, NB ), TAU( NB  ),  Y(
                          LDY, NB )

PURPOSE
       DLAHRD  reduces  the  first  NB  columns of a real general n-by-(n-k+1)
       matrix A so that elements below the  k-th  subdiagonal  are  zero.  The
       reduction  is performed by an orthogonal similarity transformation Q' *
       A * Q. The routine returns the matrices V and T which determine Q as  a
       block reflector I - V*T*V', and also the matrix Y = A * V * T.

       This is an OBSOLETE auxiliary routine.
       This routine will be 'deprecated' in a  future release.
       Please use the new routine DLAHR2 instead.

ARGUMENTS
       N       (input) INTEGER
               The order of the matrix A.

       K       (input) INTEGER
               The offset for the reduction. Elements below the k-th subdiago-
               nal in the first NB columns are reduced to zero.
```

```
NB      (input) INTEGER
        The number of columns to be reduced.

A       (input/output) DOUBLE PRECISION array, dimension (LDA,N-K+1)
        On entry, the n-by-(n-k+1) general matrix A.  On exit, the ele-
        ments on and above the k-th subdiagonal in the first NB columns
        are overwritten with the corresponding elements of the  reduced
        matrix; the elements below the k-th subdiagonal, with the array
        TAU, represent the matrix Q as a product of elementary  reflec-
        tors.  The  other  columns  of  A  are  unchanged.  See Further
        Details.  LDA     (input) INTEGER The leading dimension of  the
        array A.  LDA >= max(1,N).

TAU     (output) DOUBLE PRECISION array, dimension (NB)
        The  scalar  factors  of the elementary reflectors. See Further
        Details.

T       (output) DOUBLE PRECISION array, dimension (LDT,NB)
        The upper triangular matrix T.

LDT     (input) INTEGER
        The leading dimension of the array T.  LDT >= NB.

Y       (output) DOUBLE PRECISION array, dimension (LDY,NB)
        The n-by-nb matrix Y.

LDY     (input) INTEGER
        The leading dimension of the array Y. LDY >= N.

FURTHER DETAILS
       The matrix Q is represented as a product of nb elementary reflectors

          Q = H(1) H(2) . . . H(nb).

       Each H(i) has the form

          H(i) = I - tau * v * v'

       where tau is a real scalar, and v is a real vector with
       v(1:i+k-1)  =  0,  v(i+k)  =  1;  v(i+k+1:n)  is  stored  on  exit   in
       A(i+k+1:n,i), and tau in TAU(i).

       The  elements of the vectors v together form the (n-k+1)-by-nb matrix V
       which is needed, with T and Y, to apply the transformation to the unre-
       duced  part  of  the  matrix,  using  an  update of the form: A := (I -
       V*T*V') * (A - Y*V').

       The contents of A on exit are illustrated by the following example with
       n = 7, k = 3 and nb = 2:
```

```
( a   h   a   a   a )
( a   h   a   a   a )
( a   h   a   a   a )
( h   h   a   a   a )
( v1  h   a   a   a )
( v1  v2  a   a   a )
( v1  v2  a   a   a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

      LOGICAL FUNCTION DLAISNAN( DIN1, DIN2 )

      .. Scalar Arguments ..
      DOUBLE PRECISION   DIN1, DIN2
      ..

 Purpose:
 =============

 This routine is not for general use.  It exists solely to avoid
 over-optimization in DISNAN.

 DLAISNAN checks for NaNs by comparing its two arguments for
 inequality.  NaN is the only floating-point value where NaN != NaN
 returns .TRUE.  To check for NaNs, pass the same variable as both
 arguments.

 A compiler must assume that the two arguments are
 not the same variable, and the test will not be optimized away.
 Interprocedural or whole-program optimization may delete this
 test.  The ISNAN functions will be replaced by the correct
 Fortran 03 intrinsic once the intrinsic is widely available.

  Arguments:
  ==========

  [in] DIN1
          DIN1 is DOUBLE PRECISION

  [in] DIN2
          DIN2 is DOUBLE PRECISION
          Two numbers to compare for inequality.

NAME
       DLALN2  - a system of the form (ca A - w D ) X = s B or (ca A' - w D) X
       = s B with possible scaling ("s") and perturbation of A

SYNOPSIS
       SUBROUTINE DLALN2( LTRANS, NA, NW, SMIN, CA, A, LDA, D1,  D2,  B,  LDB,
                          WR, WI, X, LDX, SCALE, XNORM, INFO )

           LOGICAL        LTRANS

           INTEGER        INFO, LDA, LDB, LDX, NA, NW

           DOUBLE         PRECISION CA, D1, D2, SCALE, SMIN, WI, WR, XNORM

           DOUBLE         PRECISION A( LDA, * ), B( LDB, * ), X( LDX, * )
```

```
Purpose
=======

 DLALN2 solves a system of the form  (ca A - w D ) X = s B
 or (ca A' - w D) X = s B   with possible scaling ("s") and
 perturbation of A.  (A' means A-transpose.)

 A is an NA x NA real matrix, ca is a real scalar, D is an NA x NA
 real diagonal matrix, w is a real or complex value, and X and B are
 NA x 1 matrices -- real if w is real, complex if w is complex.  NA
 may be 1 or 2.

 If w is complex, X and B are represented as NA x 2 matrices,
 the first column of each being the real part and the second
 being the imaginary part.

 "s" is a scaling factor (.LE. 1), computed by DLALN2, which is
 so chosen that X can be computed without overflow.  X is further
 scaled if necessary to assure that norm(ca A - w D)*norm(X) is less
 than overflow.

 If both singular values of (ca A - w D) are less than SMIN,
 SMIN*identity will be used instead of (ca A - w D).  If only one
 singular value is less than SMIN, one element of (ca A - w D) will be
 perturbed enough to make the smallest singular value roughly SMIN.
 If both singular values are at least SMIN, (ca A - w D) will not be
 perturbed.  In any case, the perturbation will be at most some small
 multiple of max( SMIN, ulp*norm(ca A - w D) ).  The singular values
 are computed by infinity-norm approximations, and thus will only be
 correct to a factor of 2 or so.

 Note: all input quantities are assumed to be smaller than overflow
 by a reasonable factor.  (See BIGNUM.)

Arguments
==========

 LTRANS  (input) LOGICAL
         =.TRUE.:  A-transpose will be used.
         =.FALSE.: A will be used (not transposed.)

 NA      (input) INTEGER
         The size of the matrix A.  It may (only) be 1 or 2.

 NW      (input) INTEGER
         1 if "w" is real, 2 if "w" is complex.  It may only be 1
         or 2.

 SMIN    (input) DOUBLE PRECISION
         The desired lower bound on the singular values of A.  This
```

```
        should be a safe distance away from underflow or overflow,
        say, between (underflow/machine precision) and  (machine
        precision * overflow ).  (See BIGNUM and ULP.)

CA      (input) DOUBLE PRECISION
        The coefficient c, which A is multiplied by.

A       (input) DOUBLE PRECISION array, dimension (LDA,NA)
        The NA x NA matrix A.

LDA     (input) INTEGER
        The leading dimension of A.  It must be at least NA.

D1      (input) DOUBLE PRECISION
        The 1,1 element in the diagonal matrix D.

D2      (input) DOUBLE PRECISION
        The 2,2 element in the diagonal matrix D.  Not used if NW=1.

B       (input) DOUBLE PRECISION array, dimension (LDB,NW)
        The NA x NW matrix B (right-hand side).  If NW=2 ("w" is
        complex), column 1 contains the real part of B and column 2
        contains the imaginary part.

LDB     (input) INTEGER
        The leading dimension of B.  It must be at least NA.

WR      (input) DOUBLE PRECISION
        The real part of the scalar "w".

WI      (input) DOUBLE PRECISION
        The imaginary part of the scalar "w".  Not used if NW=1.

X       (output) DOUBLE PRECISION array, dimension (LDX,NW)
        The NA x NW matrix X (unknowns), as computed by DLALN2.
        If NW=2 ("w" is complex), on exit, column 1 will contain
        the real part of X and column 2 will contain the imaginary
        part.

LDX     (input) INTEGER
        The leading dimension of X.  It must be at least NA.

SCALE   (output) DOUBLE PRECISION
        The scale factor that B must be multiplied by to insure
        that overflow does not occur when computing X.  Thus,
        (ca A - w D) X  will be SCALE*B, not B (ignoring
        perturbations of A.)  It will be at most 1.

XNORM   (output) DOUBLE PRECISION
        The infinity-norm of X, when X is regarded as an NA x NW
```

```
         real matrix.

  INFO    (output) INTEGER
         An error flag.  It will be set to zero if no error occurs,
         a negative number if an argument is in error, or a positive
         number if  ca A - w D  had to be perturbed.
         The possible values are:
         = 0: No error occurred, and (ca A - w D) did not have to be
                perturbed.
         = 1: (ca A - w D) had to be perturbed to make its smallest
              (or only) singular value greater than SMIN.
         NOTE: In the interests of speed, this routine does not
               check the inputs for errors.

NAME
       DLAMCH - determine double precision machine parameters

SYNOPSIS
       DOUBLE PRECISION FUNCTION DLAMCH( CMACH )

           CHARACTER    CMACH

 Purpose
 =======

  DLAMCH determines double precision machine parameters.
```

```
 Arguments
 =========

  CMACH   (input) CHARACTER*1
          Specifies the value to be returned by DLAMCH:
          = 'E' or 'e',   DLAMCH := eps
          = 'S' or 's ,   DLAMCH := sfmin
          = 'B' or 'b',   DLAMCH := base
          = 'P' or 'p',   DLAMCH := eps*base
          = 'N' or 'n',   DLAMCH := t
          = 'R' or 'r',   DLAMCH := rnd
          = 'M' or 'm',   DLAMCH := emin
          = 'U' or 'u',   DLAMCH := rmin
          = 'L' or 'l',   DLAMCH := emax
          = 'O' or 'o',   DLAMCH := rmax

          where

          eps   = relative machine precision
          sfmin = safe minimum, such that 1/sfmin does not overflow
          base  = base of the machine
          prec  = eps*base
          t     = number of (base) digits in the mantissa
          rnd   = 1.0 when rounding occurs in addition, 0.0 otherwise
          emin  = minimum exponent before (gradual) underflow
          rmin  = underflow threshold - base**(emin-1)
          emax  = largest exponent before overflow
          rmax  = overflow threshold  - (base**emax)*(1-eps)

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
```

```
     October 31, 1992

     .. Scalar Arguments ..
<       LOGICAL            IEEE1, RND >
<       INTEGER            BETA, T >
     ..

  Purpose
  =======

  DLAMC1 determines the machine parameters given by BETA, T, RND, and
  IEEE1.

  Arguments
  =========

  BETA    (output) INTEGER
          The base of the machine.

  T       (output) INTEGER
          The number of ( BETA ) digits in the mantissa.

  RND     (output) LOGICAL
          Specifies whether proper rounding  ( RND = .TRUE. )  or
          chopping  ( RND = .FALSE. )  occurs in addition. This may not
          be a reliable guide to the way in which the machine performs
          its arithmetic.

  IEEE1   (output) LOGICAL
          Specifies whether rounding appears to be done in the IEEE
          'round to nearest' style.

  Further Details
  ===============

  See Malcolm M. A. (1972) Algorithms to reveal properties of
      floating-point arithmetic. Comms. of the ACM, 15, 949-951.

*     ..
*     .. Data statements ..
      DATA               FIRST / .TRUE. /
*     ..
*     .. Executable Statements ..
*
      IF( FIRST ) THEN
         FIRST = .FALSE.
         ONE = 1
*
*        LBETA,  LIEEE1,  LT and  LRND  are the  local values  of  BETA,
*        IEEE1, T and RND.
*
*        Throughout this routine  we use the function  DLAMC3  to ensure
*        that relevant values are  stored and not held in registers,  or
*        are not affected by optimizers.
*
*        Compute  a = 2.0**m  with the  smallest positive integer m such
*        that
*
*           fl( a + 1.0 ) = a.
*
         A = 1
```

```
      C = 1
*
*+    WHILE( C.EQ.ONE )LOOP
   10 CONTINUE
      IF( C.EQ.ONE ) THEN
         A = 2*A
         C = DLAMC3( A, ONE )
         C = DLAMC3( C, -A )
         GO TO 10
      END IF
*+    END WHILE
*
*     Now compute  b = 2.0**m  with the smallest positive integer m
*     such that
*
*        fl( a + b ) .gt. a.
*
      B = 1
      C = DLAMC3( A, B )
*
*+    WHILE( C.EQ.A )LOOP
   20 CONTINUE
      IF( C.EQ.A ) THEN
         B = 2*B
         C = DLAMC3( A, B )
         GO TO 20
      END IF
*+    END WHILE
*
*     Now compute the base.  a and c  are neighbouring floating point
*     numbers  in the  interval  ( beta**t, beta**( t + 1 ) )  and so
*     their difference is beta. Adding 0.25 to c is to ensure that it
*     is truncated to beta and not ( beta - 1 ).
*
      QTR = ONE / 4
      SAVEC = C
      C = DLAMC3( C, -A )
      LBETA = C + QTR
*
*     Now determine whether rounding or chopping occurs,  by adding a
*     bit  less  than  beta/2  and a  bit  more  than  beta/2  to  a.
*
      B = LBETA
      F = DLAMC3( B / 2, -B / 100 )
      C = DLAMC3( F, A )
      IF( C.EQ.A ) THEN
         LRND = .TRUE.
      ELSE
         LRND = .FALSE.
      END IF
```

```
         F = DLAMC3( B / 2, B / 100 )
         C = DLAMC3( F, A )
         IF( ( LRND ) .AND. ( C.EQ.A ) )
     $      LRND = .FALSE.
*
*        Try and decide whether rounding is done in the  IEEE  'round to
*        nearest' style. B/2 is half a unit in the last place of the two
*        numbers A and SAVEC. Furthermore, A is even, i.e. has last  bit
*        zero, and SAVEC is odd. Thus adding B/2 to A should not  change
*        A, but adding B/2 to SAVEC should change SAVEC.
*
         T1 = DLAMC3( B / 2, A )
         T2 = DLAMC3( B / 2, SAVEC )
         LIEEE1 = ( T1.EQ.A ) .AND. ( T2.GT.SAVEC ) .AND. LRND
*
*        Now find  the  mantissa, t.  It should  be the  integer part of
*        log to the base beta of a,  however it is safer to determine  t
*        by powering.  So we find t as the smallest positive integer for
*        which
*
*           fl( beta**t + 1.0 ) = 1.0.
*
         LT = 0
         A = 1
         C = 1
*
*+       WHILE( C.EQ.ONE )LOOP
   30    CONTINUE
         IF( C.EQ.ONE ) THEN
            LT = LT + 1
            A = A*LBETA
            C = DLAMC3( A, ONE )
            C = DLAMC3( C, -A )
            GO TO 30
         END IF
*+       END WHILE
*
      END IF
*
      BETA = LBETA
      T = LT
      RND = LRND
      IEEE1 = LIEEE1
      RETURN
*
*     End of DLAMC1
*
      END
*
```

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
     October 31, 1992

     .. Scalar Arguments ..
<       LOGICAL            RND >
<       INTEGER            BETA, EMAX, EMIN, T >
<       DOUBLE PRECISION   EPS, RMAX, RMIN >
     ..

  Purpose
  =======

  DLAMC2 determines the machine parameters specified in its argument
  list.

  Arguments
  =========

  BETA    (output) INTEGER
          The base of the machine.

  T       (output) INTEGER
          The number of ( BETA ) digits in the mantissa.

  RND     (output) LOGICAL
          Specifies whether proper rounding  ( RND = .TRUE. )  or
          chopping  ( RND = .FALSE. )  occurs in addition. This may not
          be a reliable guide to the way in which the machine performs
          its arithmetic.

  EPS     (output) DOUBLE PRECISION
          The smallest positive number such that

             fl( 1.0 - EPS ) .LT. 1.0,

          where fl denotes the computed value.

  EMIN    (output) INTEGER
          The minimum exponent before (gradual) underflow occurs.

  RMIN    (output) DOUBLE PRECISION
          The smallest normalized number for the machine, given by
          BASE**( EMIN - 1 ), where  BASE  is the floating point value
          of BETA.
```

```
EMAX    (output) INTEGER
        The maximum exponent before overflow occurs.

RMAX    (output) DOUBLE PRECISION
        The largest positive number for the machine, given by
        BASE**EMAX * ( 1 - EPS ), where  BASE  is the floating point
        value of BETA.

Further Details
===============

The computation of  EPS  is based on a routine PARANOIA by
W. Kahan of the University of California at Berkeley.

  -- LAPACK auxiliary routine (version 1.1) --
     Univ. of Tennessee, Univ. of California Berkeley, NAG Ltd.,
     Courant Institute, Argonne National Lab, and Rice University
     October 31, 1992

     .. Scalar Arguments ..
<       DOUBLE PRECISION   A, B >
     ..

  Purpose
  =======

  DLAMC3  is intended to force  A  and  B  to be stored prior to doing
  the addition of  A  and  B ,  for use in situations where optimizers
  might hold one of these in a register.

  Arguments
  =========

  A, B    (input) DOUBLE PRECISION
          The values A and B.

     October 31, 1992

     .. Scalar Arguments ..
<       INTEGER            BASE, EMIN >
<       DOUBLE PRECISION   START >
     ..

  Purpose
  =======

  DLAMC4 is a service routine for DLAMC2.

  Arguments
  =========

  EMIN    (output) EMIN
          The minimum exponent before (gradual) underflow, computed by
          setting A = START and dividing by BASE until the previous A
          can not be recovered.
```

```
  START   (input) DOUBLE PRECISION
          The starting point for determining EMIN.

  BASE    (input) INTEGER
          The base of the machine.
